Mr. MAKINS showed a man aged thirty-four who went to him three years ago with a large Ilio-femoral Aneurysm. As he could not be sure of room enough to ligature the external iliac artery he made his incision through the semilunar line, not exclusively through fibrous tissue, and managed to ligature the external iliac artery. The patient was up and about by the forty-seventh day. Within three months he went back complaining of pain in the groin on the opposite side, where there was a pulsating swelling not so large as the previous one. He (Mr. Makins) took it to be due to gummatous arteritis, and repeated the operation. This time the patient got well much more rapidly than on the first occasion, the collateral circulation being established more promptly. This he attributed to the ligature of the other external iliac artery having dilated the vessels to some extent. He mentioned that he had tied the epigastric artery because it led directly into the sac. The patient had worn a belt ever since and had no hernia, though he was a carpenter and worked hard.—Mr. THOMAS SMITH asked Mr. Makins whether, if he were free to choose between the two operations, he would deliberately choose the transperitoneal operation.—Mr. MAKINS said, in reply, the operation through the peritoneum was the easier of the two, but if he knew for certain that he could get at the artery without cutting through the peritoneum he would prefer to do so. His reason for operating thus, in the first instance, was that he could not be certain of being able to ligature the external iliac and might have been obliged to tie the common iliac. On the second occasion, as the patient had done well after the first operation, he thought it best to repeat the procedure.

Dr. HARRY CAMPBELL showed a lad fourteen years of age who had been under observation for upwards of ten years. When he was only fifteen months old his mother noticed that hair was beginning to grow upon the pubes and that the external genitals were abnormally large. At two years of age they were fully developed, and had not materially altered during the last ten years. He had at times manifested great sexual excitement. Between four and seven years of age he had frequent discharges of seminal fluid, but Dr. Campbell had never been able to satisfy himself of the presence of spermatozoa. His muscular development was remarkable; in fact, he had the muscles of a man aged twenty-five or thirty. He had been in the habit of getting shaved for the last few years. His education was defective because no school would ever take him in. He had had the gruff voice of a man since the age of two.

Mr. MORGAN showed a child aged three years and a half with well-marked Harelip and Cleft Palate, together with defective development of the left side of the face, and abnormal formation of the left external ear, of which the meatus was wanting. In addition, he presented a curious band of skin in the left trapezius region in which no muscle could be felt. On the opposite side the trapezius was hypertrophied, and there was a large mass of bone, probably representing a rotated cervical vertebra. Mr. Morgan had endeavoured to unite the palate, but had been obliged to desist owing to the hæmorrhage.

BRITISH GYNÆCOLOGICAL SOCIETY.

Porro's Operation for Labour complicated by Uterine Fibroids.—Unusual Complications in Two Cases of Removal of the Ovaries and Fallopian Tubes.—Glycosuria complicating an Ovarian Tumour and Ovariotomy.—Exhibition of Specimens.

A MEETING of this society was held on Nov. 14th, Dr. CLEMENT GODSON, President, being in the chair.

Dr. MUTCH (Nottingham) read for Dr. GEORGE ELDER (Nottingham), in his absence, a paper on a Case of Porro's Operation for Labour complicated by Uterine Fibroids. The patient was a primipara aged thirty-five years. The fibroid had not been observed till labour set in, when it was found occupying the pelvis; the uterus was jammed against and above the symphysis. An attempt to elevate the obstruction was quickly found to be useless. Porro's operation was therefore performed. The child was delivered alive. The stump of the uterus was secured in the usual extra-peritoneal fashion. The patient made a good recovery.—The PRESIDENT observed that of late Porro's operation had been heard of less often owing to the success which Cæsarean section had achieved. He believed he was the first to perform a successful Porro's operation in Great Britain, but still he would now perform Cæsarean section in preference if the case permitted.—Dr. HEYWOOD SMITH said that fibroids generally ceased to grow during pregnancy, becoming flattened and often atrophied.—Dr. LEITH NAPIER believed the reverse was the case, and that fibroids usually grew during pregnancy, sharing also in the subsequent involution.—Dr. MACNAUGHTON JONES said there were many cases on record of large fibroids continuing to grow but still remaining undiscovered up to a late stage of pregnancy. He had recorded such a case himself, in which the birth of triplets further complicated the labour.—Dr. CRICHTON (Twickenham) remembered a case in which he turned the child and then found a fibroid the size of a fist which had not been observed before. It apparently disappeared during involution; for in a subsequent pregnancy it could not be found.

Mr. SKENE KEITH read a paper on Unusual Complications in Two Cases of Removal of the Ovaries and Fallopian Tubes. The first case was one of a patient aged thirty-two years suffering from chronic disease of the appendages, which had greatly reacted on the general health. At the operation, when the right ovary had been freed from adhesions and removed, it was found that there was a distinctly localised irregular swelling, as large as a hen's egg, behind the head of the colon. His hope was that it was inflammatory, his fear that it was sarcomatous. In either case he did not think it right to interfere. Six months later there was no swelling to be felt on examination, but there was a little tenderness. This also had disappeared two months later. The second patient was aged thirty-five years. Three years ago, after an abortion, she had "inflammation in every organ of her body," as she expressed it. Pain in the right side caused her to walk as if lame; an unusual symptom was that as soon as she took food she invariably and instantly felt nauseated. The right-sided pain occupied two distinct areas, the one in the usual position of a pain caused by disease of the ovary, the other in that caused by disease of the appendix. At the operation the appendix, though healthy, was closely involved in a mass of adhesions round the enlarged ovary and tube of the right side. The feeling of nausea disappeared at once, and six months later the patient was in perfect health.

Dr. J. HALLIDAY CROOM read a paper on a case of Glycosuria complicating an Ovarian Tumour and Ovariotomy. It referred to a patient aged fifty-three years who had noticed an abdominal tumour for five months. Being excessively corpulent, the early growth was probably masked. When she presented herself at the ward of the Royal Infirmary, Edinburgh, her appearance was extraordinary. Her height was 5ft. 4½in., her weight without clothes over 17st., and the girth of the abdomen was 60 in. Her complexion was pale, lips cyanosed, and she had a distinct growth of hair on the upper lip and chin. The urine was not increased in quantity; its specific gravity was 1047, and it contained blood, a little albumin, and much sugar; the urea was normal or diminished. All other signs and symptoms of diabetes were absent. The case was regarded as one of glycosuria, probably caused by the tumour. Codeia and morphia had no effect on the amount of sugar, and as the growth was increasing and dyspnœa urgent, laparotomy was performed. There was found a colloid tumour implicating each ovary; the two together weighed 56½ lb. The sugar remained practically unaltered after the operation for eleven days. At the end of this time a course of morphia was resumed, which had an immediate effect in reducing the sugar. After ten days the morphia was stopped and the diet rigidly restricted. For a fortnight no difference in the sugar was observed; then there was a rapid diminution. Ten days later she was sent home, the urine containing a mere trace of sugar. Two months later a specimen was examined and found to be quite free from sugar. The paper concluded with a discussion of the etiology of the glycosuria.—Dr. MACNAUGHTON JONES reviewed the possible causes of the presence of sugar, whether in ovarian tumour or pregnancy, and after ovariotomy or labour. He considered pressure on the portal vein a likely cause. The interference with the hepatic circulation in the one case, and sudden release of pressure in the other, might cause glycosuria. He thought the hepatic a more likely explanation than the pancreatic, though both might coexist.—Dr. LEITH NAPIER thought the paper most valuable and suggestive. Briefly, there were were two classes of causes of glycosuria, the mechanical and the nervous; disturbances in these factors caused variations of metabolism. Morphia and its allies answered well in diabetes, but in glycosuria the group of the bromides was much more efficacious.

Mr. SKENE KEITH showed a very large Ovarian Tumour, successfully removed. It weighed over 100 lb., and was one of the largest that had been successfully removed. The patient was fifty-five years of age. The tumour was first noticed eleven years ago; for some time it so resembled a fibroid that it was diagnosed as such by seven different physicians in London at different times, and operation was not advised. Lately it had grown much, and Mr. Keith saw the patient. The cystic character was then plain. Owing to the enfeebled general condition and cardiac irregularity, he first tapped the cyst, removing 75 lb. weight of fluid; and ovariotomy was performed some days later. There were hairs in the cyst, and the second ovary was the seat of a dermoid. For a week the patient's condition was so bad as to require digitalin in $\frac{1}{70}$ gr. doses every two hours for the whole of that time. It was now six weeks since the operation, and the patient was doing well.—The PRESIDENT, Dr. LEITH NAPIER, and Mr. GEORGE KEITH addressed the meeting.

Dr. HEYWOOD SMITH showed a specimen of Ectopic Gestation at four months. The patient, aged thirty-eight, had had four children, the youngest six and a half years previously. This illness came on with the characters of a miscarriage; and when Dr. Heywood Smith saw her there was a tumour nearly filling the pelvis. On abdominal section it turned out to be an extra-uterine gestation.—Dr. T. W. EDEN, who had examined the specimen, reported that the placenta was enormously enlarged by hæmorrhage into its substance, and that the fœtus was of a development corresponding to the beginning of the fourth month. There was a curious adhesion of the head of the fœtus to the amnion.

Dr. LEITH NAPIER showed a Uterus removed by Vaginal Hysterectomy for Menopastic Endometritis becoming Sarcomatous.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A National System of Registration of Sickness.

A MEETING of this society was held on Nov. 21st, Mr. VACHER, President, being in the chair.

Dr. NEWSHOLME opened a discussion on a National System of Registration of Sickness by observing that it was through the impulse it had given to the provision of hospitals, disinfecting stations, &c., that the notification of infectious diseases had been most useful, for the mere tabulation of cases was of no possible service, and to compare the mortality from such diseases in a town before and after the adoption of the Act, or, as Mr. Biddle did, in towns in which it was in operation with those in which it was not, without taking all other differing conditions into account, was most misleading; whilst such short periods of observation as four years might easily be made to

Digitized by Google

include two epidemic years in one term, and to exclude such recurring prevalence from another. It was only by notification of every case that that knowledge of the causes of a disease is acquired which must precede measures for its prevention, and there were preventable diseases other than the infectious. Of these the most important was tuberculosis, the extinction of which would effect a greater reduction in the death-rate than would that of several infectious diseases put together, and which might be banished as completely as leprosy had been. Acute rheumatism, pneumonia, and others appeared from their greater frequency in some localities and in certain occupations to be more or less preventable. Industrial diseases—as anthrax, arsenic, lead, and other poisonings—should be notified, but always to the medical officer of health in the first instance, and not, as enjoined by Section 29 of the Factory Act of 1895, to the chief inspector of factories only; the preliminary inquiry implied in the wording of the clause as to whether the disease was, or was not, caused by the conditions of the trade or factory should devolve on the medical officer of health and not on the practitioner attending the operatives. Compulsory notification of a number of diseases deemed preventable though not all communicable, either immediately or periodically according to their nature, had for some years worked very successfully in Germany and Scandinavia. The Statistical Yearbook of the city of Berlin was a mine of information with which our Registrar-General's reports would not bear comparison, though as regards infectious diseases only, those of the Metropolitan Asylums Board were excellent. But in England it was impossible to obtain any extension of the system unless immediate benefits could be assured on account of the additional expenditure, and gratuitous notification would be resisted by the medical profession unless they could obtain in exchange the legal protection against irregular practitioners enjoyed by their Continental brethren. Returns might, however, be at once requisitioned with little cost or trouble from all Poor-law surgeons, from asylums, prisons, workhouses, schools, hospitals, and dispensaries, the police, and other public services maintained wholly or in part by imperial or local taxation or by voluntary subscriptions, as well as from friendly and benefit societies, the numbers and ages of members or inmates being also furnished as a basis. Medical officers of health, if they would not be regarded as merely a higher grade of sanitary inspector, must convince the public that their functions and usefulness are not confined to sanitation and infectious diseases.

The PRESIDENT reviewed the history and legislative aspect of notification, and gave some of his experience in the North of England.

Dr. WOODFORDE, Mr. LOVETT, and Dr. YARROW attached little value to the diagnoses of parish and club medical officers, or rather of their unqualified assistants, and Dr. Yarrow deprecated the practice among a certain class of duplicate notification, which he thought might be discouraged by the payment of 1*s.* or 6*d.* for notifications after the first. His objection to the notification of erysipelas was that simple erythemas and swollen faces were described as such, an abuse that might be checked by making them liable to removal to hospital.

Dr. O. FIELD did not think club statistics more untrustworthy than those of diphtheria, and believed that in both errors corrected themselves in the mass.

Dr. SYKES held this view as to the doctrine of averages in respect of diphtheria, the unrecognised cases being probably quite as numerous as those erroneously reported, but adduced the authority of Mr. Neison and Sir E. Chadwick on the fallaciousness of club statistics. He insisted on the importance of a practical recognition of the difference between those preventable diseases, whether communicable or not, which were dangerous or benign, and of frequent or rare occurrence. Measles, for example, was an almost trivial disease, but caused more deaths than the invariably fatal hydrophobia and glanders. The immediate benefits to be derived from the notification of arsenical and lead poisoning would render its adoption easy. He considered that in Germany statistics were pushed to an extent which in this country would be neither desirable nor practicable.

Dr. LEGG defended the accuracy and utility of German statistics, and described the systems of notification in force in several Continental countries.

Dr. WILLOUGHBY expressed his entire agreement with all that Dr. Newsholme had urged, especially as to the importance and preventability of tuberculosis, but would call his attention to the difficulties arising from the inevitable repeated notification of chronic diseases in which it would be impossible to prove the identity of the individual. A tuberculous patient would be attended successively by a private practitioner and at several hospitals or dispensaries in London and then perhaps sent to the seaside, when the same repetition would be continued. Then at many institutions letters were renewable every month, and each was entered in the report as a fresh case. The prevalence of such a disease would be enormously exaggerated, and the death-rate or case mortality proportionately under-estimated.

Dr. NEWSHOLME, in his reply, admitted the difficulty, but confessed himself quite unable to suggest such a remedy as would render the returns available for statistical purposes.

SOCIETY OF ANÆSTHETISTS.

President's Address.—Strychnia Poisoning by Hypodermic Injection.

A MEETING of this society was held on Nov. 21st, Dr. GEORGE HEWLETT BAILEY, President, being in the chair.

The PRESIDENT delivered his introductory address, in which he commented upon the large number of chloroform fatalities reported in the journals during the present year. He suggested that the meetings of the society should be occupied more in the discussion of clinical cases, and trusted that thereby the society might gather valuable information tending to diminish the present alarming mortality from chloroform administration.

Mr. RICKARD W. LLOYD, in introducing Notes on a Case of Strychnia Poisoning by Hypodermic Injection in which he administered chloroform for upwards of six hours, quoted from the address of Professor Horatio C. Wood on Anæsthesia at the International Medical Congress, Berlin, 1890: "For many years chloroform has been used in practical medicine as the physiological and practical antagonist to strychnia, and it seems rather odd that strychnine should not have been employed as the practical antagonist to chloroform." Professor Wood said also that strychnia had a marked influence in increasing respiration and some effect upon the circulation. To anæsthetists great importance attaches to the influence of chloroform in strychnia poisoning, and *vice versâ*. The hypodermic injections of strychnia were administered in medicinal doses every four hours during a period of fifty-two hours as part of the treatment of a patient aged thirty-six suffering from puerperal septicæmia. Three and a quarter hours after the last injection, and shortly before another became due, the patient complained of a little difficulty in opening the mouth, with a peculiar feeling in the head not unlike impending faintness. Bromide of potassium was given at intervals, but ten hours after the last injection the symptoms became so severe, with opisthotonos, terrified expression, impaired respiration, dilated pupils, rapid pulse, and convulsive spasms, that the administration of chloroform was commenced and continued for two hours. After one hour's interval the chloroform had to be recommenced on account of the recurrence of severe symptoms, and continued for another two hours, and subsequently was administered for shorter periods—in all for six hours and seven minutes during the space of nine hours and five minutes. Nine and a half ounces of chloroform were used. The chloroform was sparingly administered upon lint held about four inches from the face, and it was remarkable how little was necessary to keep off the spasms. There was no vomiting. The patient recovered from the strychnia very soon, and ultimately from the septicæmia. Several recorded cases of strychnia poisoning treated by administration of chloroform were referred to. The difficulty or inability to swallow and the promptness with which rectal injections are expelled in cases of strychnia poisoning render medication by hypodermic injection and inhalation of vapour especially valuable methods of treatment; and, therefore, when the strychnia has been swallowed apomorphia by hypodermic injection is a most suitable emetic, and chloroform by inhalation another most applicable antidote when the spasms are severe. Having no experience of the effect of strychnia in chloroform poisoning he could only surmise that it would not be proportionately of inverse value.—Mr. JOSEPH WHITE referred to the great benefit which frequently attended the prolonged administration of chloroform in tetanus, and alluded to a number of cases of traumatic tetanus in which the use of chloroform during the more acute spasms, and extending at intervals over

Digitized by Google

many hours, had proved of the greatest advantage.—Dr. SILK thought that Mr. Lloyd's paper was of great value to anæsthetists as raising the whole question of the use of strychnia in cases of exhaustion or "shock" under anæsthetics. Dr. Silk had no experience of the antidotal action of chloroform in cases of strychnia poisoning; but with regard to the value of strychnia in the conditions of "shock" to which he had already alluded he had a very high opinion. He had employed hypodermic injections of strychnia in this condition with increasing frequency since Professor Wood of Philadelphia had drawn attention to its action at the Berlin Congress, and of late had been in the habit of injecting one-sixtieth of a grain hypodermically immediately after anæsthesia had been induced in cases in which there was reason to anticipate any serious degree of exhaustion from whatever cause, repeating the dose if need be towards the end of the operation. Dr. Silk had seen no cumulative effects following this use of the drug, but in the face of Mr. Lloyd's experience this was obviously a possibility to be borne in mind. From some few cases which had come under his notice Dr. Silk was further inclined to think that the drug was of value in preventing after-sickness, but he should not like to speak with certainty upon this point, although Mr. Lloyd's case rather supported the view.

Dr. DUDLEY BUXTON regarded the right time to use strychnine as an antagonist to chloroform to be just before the administration of the anæsthetic was commenced. If used when dangerous symptoms had occurred it was of less value, probably because it was imperfectly absorbed. The best method of its exhibition was by hypodermic injection.—Mr. EASTES recalled to mind a case where prolonged inhalation of chloroform had produced bronchitis.—Mr. TYRRELL said it would be interesting to know what dose of strychnine was given, and whether it was given every four hours night as well as day.

PLYMOUTH MEDICAL SOCIETY.

Cerebral Irritation.—Exhibition of Cases and Specimens.

AT a meeting of this society, held on Nov. 13th, Mr. SQUARE, President, being in the chair, the following cases and specimens were shown:—

Mr. J. R. ROLSTON showed a child eighteen months old with a Hard Primary Sore on the Right Upper Eyelid, Enlarged and Hard Parotid Lymph Glands, and Mottled Rash on Front of Trunk. No history could be given.

Mr. C. E. RUSSEL RENDLE exhibited (1) a woman aged fifty years from whose Left Auricle he had removed a Cirsoid Aneurysm of the Lobule which commenced to grow after the latter had been "pierced" for earrings; (2) a man aged fifty-six years with old Subcoracoid Dislocation of the Right Humerus for which no cause was assigned; suppuration in the subacromial bursa first brought this patient under treatment, and the abscess had been opened and drained seven months previously; owing to the man's age and brittle arteries any attempt at reduction was deprecated; and (3) a boy with Specific Keratitis of Right, and Choroiditis of Left, Eye.

Mr. WOOLLCOMBE (for Mr. SWAIN) showed two examples of Charcot's Joint Disease. 1. A man aged forty-three years in whom lightning and girdle pain had commenced four years previously and ataxic symptoms for the last two years; thirteen months ago the right knee enlarged painlessly, sexual desire was lost, and some difficulty of micturition occurred. For nine months he had worn a poroplastic splint, fitted after tapping and compression of joint by a rubber bandage. For ten weeks he was kept on arsenic, strychnia, and belladonna. There was no history of syphilis or alcoholic excess. Ataxic symptoms had been in abeyance for the past nine months. 2. A man aged forty-six years whose right knee began to swell three months and a half ago, when ataxia developed; he had had lightning pains for two years in both legs and in the left biceps, and was never free from them for long. The leg below the affected knee also swells, and a few inches above the adductor tubercle there is a hard, elongated periosteal node.

Mr. WEBBER exhibited a young woman aged twenty-five who, when nine years old, began to lose her finger-nails, this being preceded by swelling and tenderness of the finger-tips; she was healthy-looking, well-grown, and without any signs of organic disease. The nails least atrophied are those of each ring-finger; those of each great and second toes are small, brown, and thickened; the nail and matrix of the third fingers are absent; the hands are cold, and on the fingers there are scattered papules like chilblains. Treatment now consists of the administration of 10 gr. of thyroid substance daily.

Mr. C. E. RUSSEL RENDLE showed Splints made by the skipper of a Danish schooner for Fractured Femur and Humerus in one of his crew. The fractures were kept up three days before the patient's admission into hospital, and have since done excellently.

Mr. ELLIOT SQUARE demonstrated the results of Needling Zonular Cataract in a Young Boy.

Mr. WOOLLCOMBE showed—(1) Portions of a Fibroid Tumour of the Anterior Lip of the Cervix removed per vaginam by "morcellement"; the mass filled the vagina, causing retention of urine and œdema of the extremities, but there had been no menorrhagia or metrorrhagia; and (2) Fallopian Tubes removed on the day of the meeting from a woman aged thirty-eight; for eight weeks the abdomen had enlarged, and for the past two weeks the evening temperature had ranged from 101° to 103° F. The intestines were found matted together and studded with miliary tubercle; the fimbriated ends of both tubes were glued to the back of the uterus, and their ostia were filled with caseous points.

Dr. FOX read notes of the case of a boy aged seventeen years who was admitted under Dr. Clay's care with symptoms of Cerebral Irritation. Death took place eight days after the onset of the illness, and post mortem all the ventricles were found to be distended with blood-clot accompanied by hæmorrhage into the upper end of the spinal cord.

Dr. FOX also demonstrated a Large Glioma at the Base of a Brain removed from a young man aged nineteen years.

Mr. LUCY exhibited one of two Calculi, weighing over an ounce, removed from the bladder of a man aged sixty-three who three years before had had prostatectomy performed and three-fourths of an ounce of gland tissue removed, with excellent effect, which lasted for two and a half years, when the wound reopened and discharged urine, death taking place twelve days after removal of the calculi; the ureters were found to be enormously dilated, with a "date-stone" calculus blocking the lower end of the right ureter; the kidneys were shrunken, with commencing cavities in the pyramids. No return of the prostatic overgrowth had taken place

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Notes on a Paris Hospital Visit.

THE second ordinary meeting of this society was held on Nov. 20th, at the Medical Institute, Birmingham, Dr. T. EDGAR UNDERHILL, the President, being in the chair.

Mr. J. T. J. MORRISON showed a specimen of Exostosis of unusual size, which he had removed from the lower end of the left femur. The patient was a man aged twenty-two who had been aware of the swelling for sixteen years. It had not interfered with locomotion or caused any pain, but it had led to his rejection as a candidate for the police force. Mr. Morrison briefly discussed the etiology of cancellous exostoses springing from epiphysial cartilage, and remarked on the advantage of operating by the bloodless method and of dressing the wound without drainage before removing the Esmarch tube. In the present case the bony pedicles had been chiselled through. The deep wound had healed in a few days by first intention, and the patient is now active on police duty.

Dr. LESLIE PHILLIPS showed: 1. A case of Lymphangioma Circumscriptum Cutis in a girl aged seventeen years. The patch is situated over the right scapula and was stated to have been of six months' duration. It is the size of a small hand, fawn or straw-coloured, and consisted of aggregated, raised, flattened, resisting vesicles almost verrucous in character. Over much of the eruption vascular tufts are seen, giving it an ecchymosed appearance in places. The vesicles when punctured exude lymph. There are no subjective symptoms. The patient has red hair, and the angles of the mouth are scarred. The exhibitor expressed doubt as to the reliability of the reputed duration of the disorder. As the eruption was out of sight and did not give rise to inconvenience it is probable that its onset was not accurately observed. 2. A man with Lichen Ruber Planus of three

Digitized by Google

months' duration; it is notable that it began acutely as an eruption indistinguishable from patchy erythemato-squamous eczema—a character which still persists in some of the lesions.

Dr. MALINS showed a large Cystic Ovarian Tumour the chief peculiarity of which was two broad pedicles. The ovaries were firmly united, probably from pelvic pressure in early growth. They had increased rapidly in size, one large cyst reaching up to the liver on the right side. The patient was single, aged thirty-six, and was in good health up to June. A week before admission to hospital she had been tapped, eighty ounces of fluid of sp. gr. 1019 being evacuated from the cyst on the right side. The pedicles were tied in several divisions with prepared silk; recovery was without incident.

Mr. HEATON showed for Mr. LAW WEBB a Dermoid Ovarian Cyst removed from a woman aged forty. The cyst when removed contained the usual pultaceous fatty material found in such cysts. Attached to the cyst wall at one point was a portion of a jaw having four well-formed teeth firmly fixed in it. They resembled the incisor and præmolar teeth of a child six years old. From another point in the cyst wall there grew a tuft of fine silky hair some four or six inches in length.

Mr. PROSSER showed a patient with a Purpuric Eruption covering the entire body.

Mr. GAMGEE showed a specimen of Ruptured Tubal Pregnancy. The patient, aged thirty-nine, has had five children born alive and one miscarriage, the latter seven months ago. Since then she menstruated regularly every five weeks; she lost some blood on Sept. 18th, this being the time when she expected to menstruate. On Sept. 19th she had some abdominal pain, and on Sept. 22nd felt sudden violent abdominal pain, vomited, and became collapsed. Laparotomy was performed twelve hours after onset of the symptoms. The pelvis and lower part of abdomen were full of blood. Left tubal pregnancy, which had ruptured, was found. The broad ligament was ligatured with silk, and the tube removed. The abdomen was cleaned by sponging. Following the operation the patient had a severe attack of bronchitis, but had no abdominal symptoms, and was discharged recovered on Oct. 24th.

Mr. WM. THOMAS read a paper entitled "Notes on a Paris Hospital Visit." The hospitals visited were the Hôtel-Dieu, Laennec, and one of the hospitals for sick children. He described the wards, and contrasted them somewhat unfavourably with those of English hospitals. He spoke with approval of the system of "consultations" instead of out-patient practice, and described several operations which he saw performed, noting some points which might give rise to discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Cancer of the Bowel.—Ovariotomy.—The Treatment of Heart Disease.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 21st, the President, Dr. PORTER, being in the chair.

Mr. SNELL introduced a woman aged sixty-one years with a Malignant Tumour, probably epitheliomatous, involving the outer half of the left upper eyelid. It appeared to have commenced two years previously.

Dr. T. H. MORTON read the notes of an obscure and doubtful case of Cancer of the Bowel. There was a slimy bloody discharge in which spheroidal cells were revealed by microscopical examination.—Dr. MORTON also exhibited Bones which he readily and successfully amputated by his Serrated Pliers.

Dr. CLAPHAM showed a large Ulcer of the Stomach adherent to the Pancreas and Liver. Two months before death what was equivalent to a perforation occurred, and the resulting inflammation was indicated by fine connective tissue adhesions all over the under surface of the liver and a milky coating on the transverse colon. Death was caused by hæmorrhage. An open artery of considerable calibre was conspicuous on the base of the ulcer.

Dr. BURGESS showed a Tumour of the Left Optic Thalamus. There was paralysis of the right side of the face and right arm, but not of the right leg, and there was no hemianæsthesia.

Dr. CUFF demonstrated Microscopic Specimens.

Dr. KEELING gave the details of a case of Ovariotomy for removal of a Suppurating Fibroid Tumour of the Ovary. In separating adhesions the small intestine was wounded in two places, and after the operation partial paralysis of the right arm and hand and of the left leg was found to have occurred. In spite of these mishaps rapid recovery took place. The tumour appeared from microscopical examination by Dr. Wilkinson to be simply fibrous with a rugged cavity at the top from which a pint and a half of pus were removed at the operation.

Dr. HUNT read a paper on the Treatment of Heart Disease. He related cases in which he had used baths to strengthen the heart and reduce its velocity. Though his own experience did not warrant him in coming to any very definite conclusion, he was persuaded that a bath colder than the temperature of the body strengthened and slowed the pulse. The good effects of rest and certain cardiac tonics were briefly referred to. In conclusion, Dr. Hunt drew attention to the excellent results he had obtained in cases of high arterial tension by the use of nitrites.—The PRESIDENT, Mr. PYE-SMITH, Mr. ARTHUR JACKSON, Dr. SAMSON MATHEWS, Mr. KNIGHT, Mr. MAKEIG JONES, and Mr. RICHARD PAGE took part in the discussion.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Enterotomy and Enterectomy.—Exhibition of Specimen.

A MEETING of this society was held on Nov. 20th, Dr. MUTCH, President, being in the chair.

Mr. CHICKEN read a paper entitled "Enterotomy and Enterectomy." With reference to abdominal incisions he advocated making them as far as possible through muscular substance, as the usual incision in the linea alba left a weak scar which conduced to ventral hernia. The first step in looking for the site of intestinal mischief should be to examine the cæcal region; if no local inflammatory mischief were found there, the state of distension or otherwise of the cæcum was a guide as to whether the obstruction was below or above that viscus. The best method of finding the colon when the operation of colotomy was being performed was discussed, and the necessity of leaving a good "spur" insisted on. In uniting divided bowel he preferred to use Murphy's button to tedious suturing. The whole rectum as high as the promontory of the sacrum might be excised with facility by means of Cripps' method. It was important to operate early in cases of cancer before the surrounding tissues were infiltrated. The treatment applicable to rectal prolapse and occlusion respectively was also discussed.—Dr. MICHIE thought if pain was localised near the umbilicus or somewhat higher it indicated obstruction of small intestine, while fixed pain elsewhere indicated obstruction of the large intestine and its seat.—Mr. GRAY, Dr. HUNTER, and Mr. ANDERSON also discussed the subject.

Dr. MICHIE showed a portion of Large Intestine affected by a Carcinoma, which he had excised from a patient who had had complete obstruction for twelve days.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Exhibition of Specimens.

A MEETING of this society was held on Nov. 13th, Dr. HUTTON, President, being in the chair.

The PRESIDENT showed the Heart from a case of Congenital Heart Disease in a child six months old. The malformations consisted of: (1) patency of the foramen ovale and ductus arteriosus; (2) incomplete formation of the septum between the ventricles; (3) dilatation of the aorta from which vessel it was probable the pulmonary artery arose; and (4) thickening and small vegetations about the tricuspid orifice (fœtal endocarditis).—The PRESIDENT also showed the Brain and Microscopic Sections from a case of Glioma of the Right Side of the Pons (pressing on the medulla) occurring in a girl four years of age. The symptoms had been observed for only eleven weeks, and consisted of right internal strabismus, optic neuritis (latent), loss of power of coördination, and slight paralysis of the limbs.

Mr. EDWARD ROBERTS and Dr. J. GRAY CLARKE showed a Tumour removed from the Orbit of a girl aged [illegible] years. The tumour, of the size of a [illegible]

Digitized by Google

under the inner angle of the orbit, was enclosed in a firm capsule, and was easily removed. Its structure was that of a spindle-celled sarcoma, with large lymph spaces running through it.

Dr. WILLIAMSOM showed for Dr. DRESCHFELD preparations from a case of Acromegaly, and also exhibited a patient suffering from the disease.

Dr. KELYNACK showed specimens from a case of Intestinal Obstruction due to Distension of a Cancerous Gall-bladder.

Reviews and Notices of Books.

Skiascopy and its Practical Application to the Study of Refraction. By EDUARD JACKSON, A.M., M.D., Professor of Diseases of the Eye in the Philadelphia Polyclinic. With twenty-six Illustrations. Philadelphia: The Edwards and Docker Company. 1895. Pp. 112.

THE author claims for this method of examination, which is familiar to most ophthalmic surgeons, that it is independent of the patient's coöperation, and that it is accurate, quickly completed, simple, and opens a path for further investigation of the refraction of the eye. To study the test, he remarks, one should as far as possible start with known conditions of refraction, with lenses of known strength, with the eye at a known distance, and should observe the character of the movements of light and shadow in the pupil which belong to these known conditions. After discussing the best term to be applied to this test, Dr. Jackson gives the reasons which have induced him to prefer that of skiascopy, which he defines as a method of measuring myopia—either the myopia originally present in the eye or that produced by a lens of known strength for the purpose of measurement. He recommends the student to familiarise himself with the appearances presented by an artificial eye such as that devised by Mr. Frost, and to use a plane mirror for reflecting the light. He points out that in emmetropia and hypermetropia with the plane mirror the image of the fundus is "erect" from whatever distance the eye is viewed, because the rays emerging from the eye are either parallel or divergent; whilst in myopia the emerging rays, being convergent, are focussed at some point in front of the eye corresponding to the degree of myopia—corresponding, in fact, to the far point of such an eye. This point he terms the point of reversal, beyond which the image is inverted. "The distance of the point of reversal from the eye being the distance from the eye to its far point is the focal distance of the lens required to correct the myopia. So that to ascertain the amount of myopia we have only to determine the point of reversal and then measure its distance from the eye." He shows by easily understood diagrams why with the plane mirror the real movement of light on the retina is with the mirror—i.e., with the area of light on the face generally in all states of refraction, and this is true for all distances of the light from the mirror, or of the light and mirror from the tested eye. With the concave mirror, on the other hand, the real movement of the area of light on the retina is against the mirror and against the light on the face in all states of refraction. "If, however," he goes on to say, "the original source of light be brought so close to the mirror that the rays from it are not rendered convergent, but continue to diverge after reflection, the immediate source of light will be a magnified image of the lamp flame situated behind the mirror, as in the case of the plane mirror; and the movement of the retinal light area will be precisely the same as with the plane mirror." Dr. Jackson dwells on the importance of securing the conditions of accuracy in the application of the skiascopy test, such as thorough darkening of the room and the use of a paraffin candle, the incandescent electric light being inapplicable except it be placed behind a piece of ground glass. Next to the candle he finds the heavy mineral oils to be the best illuminant, then gas flames reinforced with the richer hydrocarbons or used on the Welsbach mantle, and after these the ordinary gas flame. The position of the light and its proper focussing on the retina according to whether a plane or a concave mirror is used, as well as the distance of the surgeon from the patient, are also points of importance that require attention and are fully and satisfactorily discussed. Various instruments are described, and the author's practice is to employ in the great majority of cases atropine, believing it to be requisite to secure precision, in which opinion we fully coincide with him. The work as a whole is very creditable, and the practitioner who takes the trouble to master its contents will know all that can be said of this very excellent, speedy, and satisfactory mode of determining the nature and degree of both common and uncommon errors of refraction.

Twentieth Century Practice. Vol. I.: *Diseases of the Uropoietic System.* Edited by THOMAS L. STEDMAN, M.D., New York City. London: Sampson Low, Marston, and Co. 1895.

IN the first volume of a series which is to extend to twenty volumes are contained seven articles dealing with the urinary tract. Of these seven only one (Diseases of the Kidneys) is purely medical; the rest, if we may except the curiously misnamed article, Diseases of the Urine, are surgical.

The first article, by Dr. Delafield of New York, deals with the medical side of Renal Disease, including, however, some remarks on new growths. Dr. Delafield's system of classification (p. 19) is very clear and founded on a sound basis. The article is copiously illustrated with well-reproduced micro-photographs.

Surgical Diseases of the Kidneys and Ureters are undertaken by Mr. Reginald Harrison. Special attention is given to the subjects of injuries and obstructions of the ureters. To the same writer is allotted the article on Diseases and Injuries of the Bladder, commencing with rupture of that viscus. The difficulties of diagnosis in this condition are specially dwelt upon, prominence being given to Dr. Weir's test by injecting the bladder with water. In this connexion it is interesting to call to mind the discussion at the Royal Medical and Chirurgical Society on June 11th, 1895, when Mr. Walsham related a successful case of suture of a ruptured bladder when the diagnosis was established by inflating the bladder. Foreign Bodies in the Bladder, Cystitis, and Extroversion of the Bladder are next treated. With regard to the last condition, which the writer justly calls "one of the most distressing deformities to which the human body is liable," he thinks that the most likely method of affording relief is to establish a lumbar fistula in connexion with one kidney, preferably the right, and when this is permanently established to remove the other kidney. After this procedure the bladder surface being no longer contaminated with urine may be closed in. This idea is, it seems to us, eminently practical. The diagnosis and treatment of vesical calculi are very fully gone into, prominence of course being given to Bigelow's operation. Mr. Harrison does not seem very favourably impressed with the operation of litholapaxy in children, except in the case of very small stones, preferring lithotomy. The remainder of the paper deals with cystotomy, both perineal and supra-pubic. Dr. Frank G. Lydston of Chicago contributes two articles, the first on Diseases of the Prostate, the second on Diseases of the Male Urethra. Hypertrophy of the prostate naturally claims a large proportion of the space allotted to this gland, and in the writer's opinion operative measures are as a rule delayed too long, and consequently when they are undertaken have but little

Digitized by Google

chance of success. Concerning the most recent operation for the relief of the results of prostatic hypertrophy—namely, castration—Dr. Lydston speaks very cautiously. The article on Diseases of the Urethra is almost entirely devoted to gonorrhœa and its consequences. For treatment rest in bed and attention to diet are insisted on as being of paramount importance. Mr. E. Hurry Fenwick contributes an article called, we do not know why, "Diseases of the Urine." True, in the text of the paper the writer talks of morbid conditions of the urine—a title which is correct. Mr. Fenwick lays stress on the value of electric light cystoscopy, and the employment of this method has certainly been the means of clearing up the diagnosis in a vast number of cases which would otherwise have had to be left undecided. Hæmoglobinuria, paroxysmal and otherwise, are to be treated of in a separate article. The final section of the volume, by Dr. Howard A. Kelly of Baltimore, deals with Diseases of the Female Bladder and Urethra. The chief point in the paper is a full account of Dr. Kelly's very ingenious and simple method of examining the interior of the bladder by means of a straight speculum, a hand mirror, and an electric lamp. By this means the whole of the interior of the bladder can be easily seen and the ureters catheterised so as to obtain urine from either kidney separately. The value of this article is not enhanced by the introduction of many of its illustrations, which are hardly needed for the elucidation of the text. The printing and get up of the work are exceedingly good. There is a full index, and a bibliography is appended to every section.

The Law and Chemistry of Food and Drugs. By H. MANSFIELD ROBINSON, LL.D. Lond., and CECIL H. CRIBB, B.Sc. Lond., F.I.C. London: F. J. Rebman, 11, Adam-street, Strand. 1895.

WITH the prospect of the Food and Drugs Act undergoing shortly very distinct and much required modification in several of its sections, as the result of the inquiry of the Food Products Adulteration Committee, we are not sure that the publication of this work is not premature. This, however, in no way affects its merits under the present *régime*. It is written by an able solicitor—a Doctor of Laws of London—who has had considerable experience of the working of the Acts—and by the analyst who conducts the public analyses of the Strand district. The pages of Part I. (the Law of Food and Drugs) are edged with red colouring, and those of Part II. (the Chemistry of Food and Drugs) with yellow colouring, an arrangement which facilitates reference, and a device which is typical of the originality and enterprise of the publisher. The introductory chapter might well have been written for no other object than to enlist first and foremost the indignation of the lay reader at the fraudulent practices which it is said still obtain. It is certainly a black view of things. Thus he is told that the total annual consumption of milk in England and Wales is 1,740,000,000 quarts, costing £29,000,000, and that there are bought annually 20,880,000 quarts of water, which are added to this commodity, and for which the public pays £348,000. Butter is even worse, the loss to the public owing to the addition of margarine being equal annually to £609,000. Similarly, £303,000 is paid yearly for water under the name of spirits. Total amount of money sterling thrown away, £1,260,000! The pernicious effects on health due chiefly to the watering down of milk are then emphasised in similar strains, till flagrant instances, as in the making of a sum of £1200 a year by adulterating pepper, are quoted in evidence of the unscrupulous practices of the wholesale and retail trade. The writer's indignation attains a maximum in the concluding paragraph of the chapter, in which he says that owing to the free use of antiseptics being allowed in this country, while it is prohibited abroad, we are liable to be [illegible] with all kinds of abominations in the form of sausages and preserved meats made from semi-putrid materials dosed with preservatives. "*England in this respect will soon be regarded as the dust-bin of Europe, and receive all its refuse, both of meat and drink.*" [The italics are ours.] "Many of these things find their way abroad again, and when attention is called to the matter England receives the blame, and her reputation has to suffer." The scientific reader will wonder whether the writer is serious, while the lay reader will pass on with avidity to learn how law and science propose to grapple with and stifle this threatened evil, and thus gloriously save our reputation. Elsewhere, however, occurs the statement—and it is somewhat reassuring—that there is deceit, not death, in the pot, and the public are now rather swindled than poisoned. Revelations and things of a startling order aside, the legal portion of the work is well done and provides information of equal service and value to the public analyst, the lawyer, and the trader. The second part of the work, dealing with the chemistry of food and drugs, is not so much intended as a practical guide to the detection of adulteration as to enlighten the reader as to the composition of various foods and the food value of the components, and to help him to understand the principles upon which the methods employed for the detection and estimation of adulterants are based. The chapters are sensibly written, clear and free from ambiguity and exaggeration, affording a valuable and indispensable collection of material to those engaged in the operations of the Food and Drugs Act, 1875.

LIBRARY TABLE.

Furs and Fur Garments. By RICHARD DAVEY. London: The International Fur Store and The Roxburghe Press. 3*s.* 6*d.*—From the earliest times the skins of animals have been used by man to protect him from the inclemency of the weather and it is not surprising that as the art of dressing the skins became more perfected and man more civilised furs should have been used for ornamental purposes as well. Among ancient nations, and on the Continent during the Middle Ages, fur was lavishly used by the opulent, and some of our own kings and queens used it with an extravagant hand. Of a purely English fur trading company the earliest record is in 1578, when an expert was sent out to New Zealand to seek for furs, leading to the first settlement in that colony. Since that time the trade has grown to enormous proportions, but it was not until the conquest of Canada that England became firmly established in the great fur regions. To this trade one of the richest families of the present day owes the foundation of its wealth, for in 1808 John Jacob Astor founded the American Fur Company, and thus laid the corner-stone of a gigantic fortune. The book under notice is illustrated with pictures of the animals from which the different kinds of fur are obtained, and with portraits of some of the notable persons of history who have conspicuously used fur as an ornament of dress. Among the portraits is a reproduction of "The Constable de Bourbon" by Titian, one of the earliest pictures in which fur is painted with anything like realism, while the frontispiece represents Her Majesty in her magnificent ermine-trimmed coronation robes. If after reading the book we have anything to regret it is that the author has somewhat shaken our faith with regard to two stories which were the delight of our childhood. Quoting from other writers he tells us that the slipper which Cinderella dropped on the palace stairs was not made of glass at all, but that the translator mistook the word *ver*, a contraction of *ménu-ver*, the heraldic *vair* (fur), for *verre* (glass).

Digitized by Google

and that the story of the Golden Fleece is nothing more than an allegory connected with the early fur traders.

The *Edinburgh Medical Journal* for November has a paper on Congenital Nervous Disease, by Dr. W. Ireland; Dr. James Smith and Mr. C. W. Cathcart report two successful cases of Laparotomy for Appendicitis; and Dr. John Strachan has an admirable paper on Health Conditions in School Life which we commend to the notice of the London School Board. Dr. R. F. Leith contributes his paper on Ruptures of the Pancreas which recently appeared in our columns, and there are sundry other papers and articles of interest.

Clinical Sketches for November.—This comparatively young periodical is so full of appreciation of ourselves that we are chary of saying anything about it. However, we may refer to the three original articles; on Melasma, by Dr. Sansom; on Cholera, by Mr. Wynter Blyth; and on the Chalk Beds of the Thames and their Influence on Mortality from Cancer, by Mr. Arthur Haviland. There is a paper upon Fractures of the Upper Third of the Femur, referring to that of Sir William Stokes read at the recent meeting of the British Medical Association. The illustrations, which are very good, were drawn on wood by Mr. Noble Smith. We must give the editor our thanks for his appreciative paragraph about our articles, "The Battle of the Clubs."

CHRISTMAS NUMBERS.

Black and White leads off with an illustration by Bernard Partridge of "Cantat nunc Io, chorus angelorum," which has caught some of the spirit of the old religious painters. There are stories by Anthony Hope and Barry Pain which stand out among modern Christmas literature for having no reference to unhappy marriages, suicide, or adultery. Mr. Arthur Morrison obliges with a suicide, and Mr. H. D. Lowry with a more or less happy love story.

Yule Tide, Cassell's Christmas annual, has a good story by "Q." We should like to know if Ia Rosemundy's songs are real gipsy ones or "Q.'s" composition, for they have the curious wandering sad melody of the Roumanian folk songs. There are a number of coloured plates besides the big supplement, "Prisoners of War." One is called "I'll be well by Christmas." We should say this hope would not be fulfilled, for the unfortunate child who makes the remark is obviously suffering from advanced mitral regurgitation and a nutmeg liver.

The Christmas number of the *Girl's Own Paper*, entitled the "Herald Angels," has a number of stories and papers. The two most interesting are an account of "Popular Christmas Festivities in Naples" and "A Girl's Ride into Upper Butain."

The *Pall Mall Magazine's* Christmas number is excellent. Lord Ernest Hamilton contributes a thrilling story of a secret society. Hilda Johnson, a very powerful and sombre story called "Κέραμος," remarkable, too, for the excellence of its illustrations, especially the last. John J. Waller writes on Behind the Scenes at Monte Carlo, giving balance-sheets of the Casino Company, in which appear the following interesting items: "Bishop, clergy, educational and religious bodies, £12,000; the viaticum for assisting losers, £5000; number of suicides for the year, five."

It has been arranged to hold a public meeting with the object of furthering the movement for the establishment of voice-training as a branch of education. The subject has been growing in interest of late, and with a good chairman, the Bishop of Stepney, who is strongly in favour of the movement, with Sir Dyce Duckworth and other speakers, some practical result ought to follow. The meeting will take place at Cadogan House, 162, Sloane-street, on Wednesday, Dec. 4th, at 3 P.M.

New Inventions.

THE DUNLOP PNEUMATIC TYRE FOR VEHICLES.

THE subject of pneumatic tyres for vehicles of all kinds must be one of no small interest to the medical profession. There is probably no one who would more appreciate such a luxury than the country practitioner, who has to spend many hours daily in his carriage travelling over roads which are—well, not quite so smooth as asphalt, and which, from their generally bad condition, add not a little to the annual cost of repairs to his vehicle, and considerably shorten the life of his horse.

Great as has been the popularity of cycling since the introduction of pneumatic tyres, and the consequent lessening of that vibration and liability to sudden jerks with which the rider of the now almost extinct "solid" was only too familiar, it is not too much to say that the general use of pneumatic tyres in the construction of our public conveyances, such as cabs, omnibuses, &c., would be even more welcome, and would add much to their popularity. As things are at present, the iron-bound wheel goes down every hole, runs up every corresponding ascent, and jumps over every obstruction, with the most disastrous results to the "fare" and to his nerves. Not so with the pneumatic tyre. Instead of acting in like manner, the air in the inner tube is simply displaced, and the tyre absorbs, as it were, all obstructions, and keeps the vehicle steady. And, then, what a revolution such a tyre would effect in the din and noise of our streets, if it could only be applied generally. There would then be no further need to put down more of wood-paving which is now almost a necessity in all large towns with heavy traffic, for the purpose of deadening the sound, and our streets would become almost perfect "silent highways." We have said "almost" advisedly, because we should still have to reckon with the itinerant vendor of bird-whistles, &c., and with the host of urchins whose vocabulary consists of half-a-dozen words, of which "Speshul!" and "All the winners!" are most generally in use.

For carriages used by invalids and for ambulances pneumatic tyres are obviously nowadays a necessity, and for every one who uses a carriage they are most desirable. The carriage is rendered absolutely noiseless, and the ease is so great that it is possible to write comfortably in a brougham so fitted, whilst conversation can be easily carried on. But it is not only the occupant of the carriage that reaps the benefit: the draught is lessened considerably, the horse goes much more freely, and, it is claimed, retains his action far longer. Although the initial outlay for these tyres is rather high, yet they appear to be an undoubted economy, owing to the saving of wear to the carriage and the lighter work for the horse. New wheels can be supplied fitted complete with these tyres, or existing wheels can easily be altered in a few days. The company have every faith in the tyre, and guarantee to repair free of cost any carriage tyres, wheels, or rims supplied by them which shall fail within twelve months, provided, of course, that they have received fair treatment. This appears to be a very fair offer, and is made on the strength of the experience of the company that it is almost impossible to puncture their carriage tyres. Certainly the tyres of the company's own cart, which we examined, and which have been in daily use for the past five months doing business in all parts of London, did not show the slightest signs of wear, nor could we discern any cuts in them. Should, however, a puncture penetrate the inner tube, it is claimed that the vehicle could still be used for many miles without in any way damaging the tyre, and this certainly seems feasible, looking to its solid construction. An examination of the method of manufacture

Digitized by Google

reveals that the vital part of the tyre is very carefully "wrapped up" by the rubber lining, the canvas fabric, and the outer cover.

The company invite an inspection of their showrooms at 14, Regent-street, where may be seen all classes of carriages, ambulances, &c., fitted with the pneumatic tyres.

A NEW TEA INFUSER.

WE have received from Messrs. Marshall, Arthur, and Co., 180, West Regent-street, Glasgow, a teapot fitted ith a new contrivance as an infusor, and having given it trial are able to report favourably upon it. It consists of an ingenious arrangement, made obvious by inspection of the accompanying illustration, for separating

the spent tea-leaves from the hot infusion, and without opening the pot, so that the tea can be kept hot for any length of time without becoming bitter—so that, in fact, the tea is an infusion and not a decoction. We have before now noticed in these columns, and with favour, con trivances having this object in view, but the "Marguerite" teapot appears to us to be as efficacious as any, while it is one of the neatest designs in the market. The required amount of tea is placed in the strainer and the pot filled with boiling water. After the necessary time has elapsed to complete the infusion (from two to ten minutes according to the hardness of the water or taste as to strength) the knob of the lid is depressed and the leaves are separated from the water. This occurs because the under side of the knob when pressed opens a valve and permits the air previously confined in the bell-shaped vessel beneath the strainer to escape. This vessel is immediately filled with fluid in lieu of the displaced air, and the level of the fluid consequently sinks in the pot to a point below where the leaves rest. As we have said, the invention is a particularly neat one, and our practical trials have given very satisfactory results. One small thing may prove inconvenient to housekeepers. If the pot is not filled to the brim the contrivance is clearly useless, and sometimes a full pot is not wanted.

NORTH-WEST LONDON CLINICAL SOCIETY.—A clinical meeting was held at the North-West London Hospital on Nov. 20th, Dr. J. H. Stowers being in the chair. Dr. R. F. Gill read notes of a case of Pleuritic Effusion and Pulmonary Cancer. Mr. C. G. Brodie showed a case of Nævus treated by Electrolysis, and one of Congenital Dislocation of the Hip; Dr. Guthrie, a case of Plumbism and Monoplegia; Dr. Cagney, a case of Telangiectasis of the Face undergoing treatment; Mr. W. H. Battle, cases of Bullet Wound of Skull and Intestinal Obstruction by a large Gall-stone; Dr. Stowers, a case of Epithelioma of the Back, and one of Tinea Versicolor; Mr. Mayo Collier, a series of cases of Nasal Obstruction; and Mr. Jackson Clarke, Hallux Valgus and Hammer-toe.

THE ASHANTI EXPEDITION.

A LARGE detachment of officers, non-commissioned officers and men left Liverpool last Saturday for Cape Coast Castle to take part in the forthcoming expedition to Kumasi. We may assume that, whether there is to be fighting or not, there will be an expedition to Kumasi in any case. Sir Francis Scott made some very pertinent remarks before he embarked for the Gold Coast as to the differences between the conditions that existed in the 1873–74 campaign and those which obtain at the present time. We know much more about the country than we did on the last occasion; we have not now to deal with a powerful confederation of tribes, but, on the other hand, the Ashantis are better armed than they were. There is time for the organisation of a large force of native bearers for this expedition and for the arrangement of everything at the base, which will be Cape Coast Castle; and it is anticipated that the force will reach Kumasi at the end of about three weeks after starting from the base. Sir Francis Scott hopes to reach the capital in any case before the end of January, which will leave time for the return march before the rainy season sets in. The route from Cape Coast consists of thick bush, but there is a fair road to the River Prah, although there are places where there is only a narrow track and where there will be heavy work in cutting away the bush. It is expected that the expedition will advance at the rate of about eight miles a day. The accounts published by different special correspondents present on the Gold Coast in 1873–74 were highly corroborative of the truthfulness of the descriptions given by previous explorers of its climate, topography, and scenery, and of the characteristics of the tribes and races inhabiting that country. Bowdich's narrative of the mission to Ashanti in 1817 gives, for example, a very graphic and accurate description of the country and people. The Ashantis are a fine, warlike race, very superior to the other West Coast natives. The Fantis, for example, on whom they were constantly making inroads and attacks, are the reverse, for they are a weak and timid people, who cannot be trusted as bearers or transport, and invariably drop their loads and run away on being attacked. The chief difficulty to be overcome is the commissariat, and the transport of supplies for the force, and it is very probable that a store depôt will be formed on the present occasion at the River Prah where it is crossed by the troops in their advance on Kumasi. The Ashantis, as we have said, are a brave race, as our own experience has proved, but we strongly suspect that we shall have more to fear from the climate and dense bush than from the fighting qualities of the Ashantis, if they are really determined on opposing the advance of the British force. The right season has been selected for the expedition, and all practicable safeguards appear to have been taken about its preparation and arrangements in this country, and we may now safely wait events. The battalion recently disembarked at Gibraltar from the *Malabar* is now awaiting orders for Ashanti. As we have already announced, the medical arrangements for the expedition are now almost complete, and, as has been stated, Surgeon-Colonel Taylor will act as the principal medical officer. He leaves Liverpool to-day (Saturday) accompanied by five other officers of the Army Medical Staff Corps. In addition to those already named, the following officers of the Army Medical Staff Corps have been detailed for the expedition—Surgeon-Lieutenant-Colonel Blennerhasset, Surgeons-Major Hughes, Wolseley, Wilson, Beatty, Bartlett, and Hickman, Surgeons-Captain Beaver (Scots Guards), O'Callaghan, Josling, Eckersley, Corcoran, Burke, Wilson, and Maher, and Surgeon-Lieutenant Spencer.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 30, 1895.

ON Tuesday afternoon the General Medical Council got well into business. It was occupied chiefly with the Address of the President; the motion of Sir WALTER FOSTER for consideration of the petition of the British Medical Association in favour of an increase in the direct representation of the profession; and a motion by Dr. GLOVER asking the Council to refer to the Executive Committee the subject of the disciplinary powers of the qualifying bodies and the General Medical Council, with a view to bringing them into more harmonious and efficient action. A discussion also took place *in camerâ* on the case of Mr. THEOBALD, who sought unsuccessfully a rehearing of his case and restoration to the Register. Mr. THEOBALD thinks himself to have been very hardly used. It will be remembered that his name was taken off the Register for publishing and circulating a book entitled "Electro-Homœopathic Medicine," in which are contained a description and recommendation of the so-called electro-homœopathic cures and medicines of one Count MATTEI, and in which it was suggested by Mr. THEOBALD, as a registered medical practitioner, to persons suffering from disease that they should adopt such so-called cures and medicines as were therein stated to be practised and used by him. Previous to the action of the General Medical Council he had been deprived of his diploma by the Royal College of Surgeons of England—the only qualification he possessed. The Council declined to re-hear the case or to restore his name to the Register. It is difficult to say how it could do otherwise, seeing that he is no longer possessed of any qualification that would give him a title to registration. It is within the power of the Royal College of Surgeons of England to restore his qualification, but so far there has been no indication of a disposition to that course. The question at issue is not one of therapeutical opinion, but of the right of a registered medical man to give his professional sanction to a quack medicine bearing the name of a non-medical man and alleged to consist, according to chemical tests, of distilled water and a little cork. Removal from the Register seems to us a proper punishment for such an offence. How long it should continue is a matter for the qualifying body to determine rather than the General Medical Council, especially in this case.

Direct representation is not popular in the Council. Its members are quite respectful to the five elected gentlemen who represent that principle, and it is admitted that they have shown no revolutionary dispositions. But the principle is, nevertheless, cordially disliked, and before Sir WALTER FOSTER had the chance of moving his resolution in favour of an increase in the number of direct representatives, the President, in his very interesting opening address, had expressed some of the well-worn arguments against the principle. These arguments did not avail to prevent the adoption of the principle, and they are not likely to be always effective against a reasonable extension of it. Sir RICHARD QUAIN quoted with great effect the striking words of Lord RUSSELL of KILLOWEN, as we have already done. But he will not deny that these words of praise have reference quite as much to the Council as reformed in 1886 as to its original constitution. In spite of the President's arguments the motion of Sir WALTER FOSTER had two or three more adherents than it had on the previous occasion.

A motion brought forward by Dr. GLOVER, and seconded by Mr. WHEELHOUSE, based on a petition of the general meeting of the British Medical Association in favour of a more adequate recommendation of the Council as to the requirements of the qualifying bodies in the matter of practical instruction in midwifery, encountered a curious and unexpected fate. The petition mentioned in Dr. GLOVER'S motion had not been formally adopted and forwarded by the Council of the Association, as contemplated in the resolution of the annual meeting. The miscarriage was eagerly seized on by the opponents of the amendment so reasonably and yet so urgently demanded by those who have studied this subject from a practical point of view. Comparisons and distinctions were made between the resolutions of the general meetings and those of the Council of the British Medical Association as if they were out of harmony, and in the end the resolution had to be withdrawn. The subject cannot always be allowed to remain in its present form. It is not tolerable that a body of the authority of the General Medical Council of Education, consisting of all the qualifying medical bodies in the kingdom, should give out that an attendance on twelve cases of labour is a sufficient practical education in midwifery. It is not the direct representatives who will be discredited by this recommendation as it stands, and as it must some day be submitted to even a higher authority than the General Medical Council.

Dr. GLOVER was more fortunate in his motion, seconded by Dr. THORNE THORNE, for instructing the Executive Committee to revert to the consideration of the subject of the disciplinary functions of the qualifying medical authorities and of the General Medical Council, of the best means for conferring and extending them, and of bringing them into harmonious and effective coöperation. The ends aimed at in this resolution would tend to save the Council's time and money, and would impose on the qualifying bodies primarily the duty of regulating the professional conduct of their own diplomates. Such a function is fundamental in our conception of the relation of bodies that license men to practise the profession of medicine. The Executive Committee, under the lead of the late Mr. MARSHALL, did good work in initiating this inquiry. The present President and Sir JOHN SIMON have frequently urged its importance. It rests now with the Executive Committee to complete work that has been well begun and not finished.

The greater part of Wednesday was occupied in considering the reply of the Privy Council to the resolution of the Council, representing to the Privy Council "that in the opinion of the Council the standard of proficiency in medicine required from candidates at the qualifying examinations held by the Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries' Hall of Dublin, after four special inspections, has been found insufficient." The chief incident in the

Digitized by Google

discussion was a graceful acknowledgment by Mr. WHEELHOUSE of his error in saying that a candidate had been passed into the profession who had really only passed certain subjects of his final examination. The whole subject was on that day left unfinished. The Council declines to alter its report to the Privy Council, and has postponed to a later day consideration of the request to appoint surgical examiners to coöperate with the medical examiners of the Hall.

SOME confusion seems to exist, both in the profession and amongst the public, regarding the merits and demerits of the south coast—by which expression we designate, for brevity's sake, the English littoral from the Thames to the Severn—as a winter resort. On the one hand, it is often quite ignored by many who too hastily assume that only the most distant resorts can benefit the more serious cases, especially those of pulmonary disease; while, on the other hand, extravagant claims have in recent years been put forward, and we are invited to contemplate the folly of those who undertake long and toilsome journeys to secure climatic advantages which are already at hand on the Cornish and Devon coast. We venture to say that both these extreme views reveal a large ignorance of the elements of the subject, and that such confusion of things essentially different and contrasted can only bring discredit and contempt upon climatology as a branch of scientific medicine. The south coast is a most admirable and useful resort for certain cases, but from the meteorological point of view its analogy with the Riviera or Davos or Egypt is remote indeed, and such loose statements as have found currency in certain quarters are much to be regretted and reprehended. Let us contrast the south coast with a well-known district regarding which we possess fairly complete information—viz., the Riviera. The mean winter temperature of Falmouth (one of the warmest places on the coast) varies from 48° to 52° F.; that of Cannes varies from 55° to 61°. Torquay has about nineteen or twenty rainy days (by which it is understood a day on which 0·01 inch of rain falls) per month during the winter season, Ventnor about 16 or 17, while Nice has only 5 or 6. The number of bright sunny days in winter is three or four times as great on the Riviera as on the south coast. The mean relative humidity of Falmouth during the winter months varies from 82 to 88 per cent.; that of Mentone from 70 to 74. Sea-fogs and mists are common on the south coast; they are practically unknown on the Riviera. It often freezes during the day time on the south coast; very rarely on the Riviera.

We do not draw attention to these facts with any design of unduly exalting the Rivieran climate, which has certain grave disadvantages, especially the prevalence of cold winds. Still less do we wish to make light of the many climatic advantages of the south coast, of which we are fully sensible; but we plead for some scientific accuracy in these matters, and we deplore the confusion of things radically different. What, then, are the leading features of the climate of the south coast? They may be summed up as follows with substantial accuracy. The climate is one of considerable mildness and equability. Sudden changes and extremes of temperature are very rare. The amount of sunshine is large compared with the average of these islands—the winter average of sunshine on the south coast is three times that of London. The prevailing winds (except during some of the spring months) are from the south-west, and are mild and humid. In many places the local protection is good. The soil is in some places—e.g., Bournemouth, Ventnor, and the Isle of Thanet—very favourable for the purposes of a health resort. The local differences of climate—e.g., those between Cornwall and Sussex—though considerable, are much less than might be expected. To a large extent the climate is determined by the Gulf Stream, of which the influence is felt as far as the North Foreland, and, as a matter of fact, the sea is almost as warm off Ramsgate as off Penzance; still, it remains true that as we come from south-west to south-east the net influence of the climate becomes bracing and moderately tonic instead of being soft and relaxing, but the differences are probably less than is usually assumed. The climate of North Devon is practically as warm as that of South Devon, but is generally regarded as more tonic in character. The most bracing climate on the south coast is that of the Isle of Thanet, especially Margate. The south coast forms an admirable resort for many cases of anæmia, dyspepsia, and debility, impaired convalescence after acute disease and operation, tropical cachexia, some varieties of bronchitis, asthma and gout, and certain types and stages of phthisis, as well as other forms of tuberculous disease. It is not generally suitable for rheumatic and nervous affections, though to this rule there are exceptions. We cannot, of course, do more than throw out a few general hints regarding the large questions of therapeutics which these statements raise. As a general rule, where there is much irritability the Devonshire and Cornish seaboard should be preferred, while if a distinctly bracing quality is desired Sussex and Kent should be selected. The Isle of Wight occupies, both geographically and climatologically, an intermediate position. Margate, Broadstairs, Ramsgate, Dover, and Brighton are types of the most bracing resorts, while Hastings, Torquay, Falmouth, and Penzance represent various grades of the soft and soothing type of climate. Bournemouth has in some respects a unique climate, and is decidedly sedative without being relaxing. It owes its peculiar characters to the dry soil, abundance of pine forest, and proximity to, with shelter from, the sea.

The question of phthisis is, of course, the most important as it is also the most difficult in this connexion, and most of the controversies which have arisen regarding the merits or demerits of the South Coast have had relation to this disease. It cannot be said that any part of the South Coast affords an ideal resort for phthisical patients. The amount of sunshine is deficient, the number of cloudy and rainy days is too large, the relative humidity is too high, and the amount of wind and fog is too great. Still, it is undeniable that many cases of the disease do well at Hastings, Ventnor, Bournemouth, Torquay, and Penzance. These cases belong usually to one of two classes—first, incipient cases with limited and quiescent lesions; and, secondly, advanced cases where only some slight palliation and mitigation of symptoms is to be expected. The excellent accommodation, good diet, and general comfort of the south-coast resorts are

Digitized by Google

powerful auxiliaries to their considerable climatic advantages. Making every allowance, however, for the above facts, it is, we think, most undesirable to put forward any high claim for the south coast as, speaking generally, a sanatorium for phthisical patients. The results obtained, though often gratifying and even surprising, will not compete with those yielded by Egypt, Davos, South Africa, or Colorado. But many patients, especially young women, cannot or will not undertake distant journeys, and to such persons the south coast may often be recommended with excellent results. We must, however, again repeat our *caveat* against claims that are unsound and comparisons that are in every way fallacious and misleading.

THERE is a lower depth than medical aid associations to which medical men may fall if they once suffer themselves to be exploited by bodies of commercial laymen. We refer to the case of gentlemen who accept office as the servants of commercial companies. There are several of these companies in existence, as is evidenced by our Special Commissioner in his account of "The Battle of the Clubs," and the fact happily seems to be leading in some towns to the unanimous combination of the profession by way of protest and resistance. There is reason to believe that these companies are getting into their service a great number of medical men and are making a wholesale attempt to commercialise the matter of medical attendance on the poor throughout the country. We have spoken of medical attendance on the *poor*, but it is of the very essence of such a system not to be too particular as to any fine lines of demarcation between the well-to-do and the poor. These companies work essentially by a system of canvassing. With ordinary canvassers, paid a percentage on the work they do and the members they draw into the net, and with no hindrance from any sense of medical etiquette, canvassing is done on a very comprehensive scale. As our Commissioner showed in the case of Eastbourne, the better the social condition of the persons entrapped by the company's medical schemes, the better the insurance business done and the more the profit to the canvasser. It may easily be imagined how the private patients of medical men are approached and inveigled by such a system and carried off wholesale to the company, to be attended by its nominees on terms altogether incommensurate with their duty to the profession and the ability of the patients to pay. This seems to us a very serious matter indeed, and one to which the profession in all parts should direct its attention and against which it should enter its emphatic protest. We repeat that the system seems already to have taken considerable hold of the profession and of the people. From the accounts which reach us there can be little doubt that hundreds, or perhaps thousands, of medical men are becoming the servants of commercial companies hailing from Manchester, London, Liverpool, &c., and parties to the methods of business companies. It seems intolerable that commercial companies should so unblushingly intervene between medical men and the people, and it is unintelligible that any number of educated men should be found ready to lend themselves to such a system.

We can do nothing with the companies. They are not amenable to reason, authority, or the traditions of the profession. They have to make 5 per cent. for their shareholders and as much more as possible, and they have found out that the health of families can be brought into the great market out of which dividends can be extracted. The old club system was a personal transaction between an established practitioner and the people among whom he lived—probably had lived for years—and whose family attendant he was. The medical aid associations have been shown to be sweating systems, abused by mayors and councillors and men of wealth in their respective communities, and in which the working men of England, individually generous, are made to exact labour from a learned profession on terms which do not remunerate it and which do not permit of due attention to patients. Still, even so, the persons treated by the medical officers have been neighbours, open to the neighbourly influences which make for consideration and fairplay. But the intervention of commercial companies in medical business, dominated by commercial men living at a distance, and carried on for purely commercial purposes, is a new point of departure which cannot be too soon or too severely criticised by those who object to the degradation of the profession. The attendance on the working classes by the profession has been for ages a matter of consideration and accommodation. When medical education was not half so long and arduous, and not half so expensive as it is now, medical men were found to attend, on the whole faithfully and kindly, to the working classes on such terms as they could afford. With the evolution of society working men have become richer and with a strange inconsistency propose to be more exacting and less generous to medical men. In their clubs, or even perhaps in their local medical aid associations, we have some control over them, some chance of appeal to their sense of what is due to men of high education and of the need of some leisure if they are not to become mere machines for prescribing stock mixtures; but with commercial companies in Manchester or London or Liverpool coming between medical men and their honest neighbours the profession should hold no intercourse. It should do in every place what the medical profession in Eastbourne and Bexhill has done—that is, combine firmly and unanimously to form its own local provident dispensaries, admitting all medical men to the staff who care to join.

But it must go further: it must give clear instruction to gentlemen who have interest in this alliance with commercial companies that that alliance is an unholy and an unpermissible one. The great temptation offered to very young men is to accept this alliance as an easy introduction to practice. We fear, from the accounts we receive, that this bait has not been altogether unsuccessful in its appeal to men of standing in the profession with good private practices of their own. Let anyone who doubts this get the lists of the officers of such societies. As we have said, we have no control over companies; commercial men will act commercially; but we have control over medical men. They cannot resist an appeal to reason and the traditions of the profession; they cannot, *in curia conscientiæ*, acquit themselves of complicity, as servants of these companies, in canvassing. They

Digitized by Google

would not themselves think of canvassing for the patients of other men, but they are parties to it by accepting office in such companies. They may have acted inadvertently, but the fact remains, and we ask them to ponder well over what it means for the profession, of whose honour they are in this matter the guardians.

Annotations.

"Ne quid nimis."

KITCHEN BOILER EXPLOSIONS.

THE constant apprehension of an explosion, which to many householders—especially ladies—greatly detracts from the comfort derivable from a complete hot-water system, and goes far to hinder its extension to the warming of the dwelling as a whole, would, we believe, be removed and the actual risks of such a catastrophe obviated if people generally understood the real causes of these accidents. The ordinary low-pressure service which is most in use consists of a closed kitchen boiler supplied through a ball valve from a feed cistern, and a hot-water cistern on one of the upper floors, the circulation being maintained between these by means of two pipes, through the upper of which the heated water rises, to return somewhat cooled through the lower, while a vent pipe rising from the cistern gives exit to any steam and effectually prevents a rise of pressure in every part of the apparatus. The danger of the low-pressure system lies in the stoppage of both pipes by the gradual accumulation of the crust of lime salts which forms especially in bends and angles and dependent parts of their course, or by the freezing of the water in any part of both pipes after the fire has gone out. The former condition may be anticipated when a constant difficulty, not to be accounted for by leakage from taps, is found in heating the water in the cistern. The latter is not likely to occur so long as water in open vessels in the rooms or passages traversed by the pipes does not freeze, and should the pipes be exposed to the risk of freezing it may be prevented by making up the kitchen fire at night. This is the cause of explosions in churches and buildings in which the heating is intermittent, the fires being allowed to go out for two or three days together. If one pipe only be blocked the circulation of the water is interrupted, and that in the boiler being somewhat superheated, large bubbles of steam rising and collapsing in the cistern produce a regular succession of loud reports, decidedly alarming though not indicative of danger. But the greatest misery is that inflicted on themselves by timid householders who deprive themselves of the necessary convenience of the kitchen fire so long as, by freezing of the cold-water cistern, bursting of pipes, or shutting off of the supply at the main, the hot-water service is suspended. There is, however, no danger whatever in allowing the residual water in the boiler to boil away, or in keeping up a fire beneath an empty boiler for a few days, if only care be taken to effectually prevent the entrance of water from the feed cistern while the boiler is hot. Not, indeed, that even this would cause an explosion, but the sudden contact of cold water with iron at nearly a red heat might cause even the soundest plates to crack, with a result like that of upsetting a kettle on the fire, and necessitating the fixing of a new boiler. Once more, kitchen boilers do explode with fatal consequences, but only from the closure by encrustation or by freezing of both pipes, when, no exit being left, the pressure of the steam rises until the boiler plates give way with a force proportional to their strength and soundness. A safety valve, which should be so placed as to be easily inspected from time to time with the view of ascertaining that it is in working order, would prevent such an occurrence. We are glad to learn that a circular letter was last week addressed by the Board of Trade to the various water companies and local authorities calling attention to the necessity for adopting some such precautions as we have just indicated during periods of severe frost.

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

MR. SHARP'S astounding statement at the meeting of the School Board on Nov. 14th, "that the great body of medical men approve of the action of the Board with regard to medical certificates," has elicited a dignified reply from Dr. J. G. Glover, who in a letter which appeared in the *Times* of Nov. 25th, entirely repudiates this statement. Dr. Glover has a right to speak for the profession at large, for he is one of the direct representatives of the profession for England and Wales on the General Medical Council. Mr. Sharp writes to the *Times* of Nov. 28th in reply, which reply mainly consists of a reprint of a letter addressed to the chairman of the committee of the Royal Westminster Ophthalmic Hospital. In the *Times* of Nov. 28th are three letters, all from medical men, including a second from Dr. Glover disposing of Mr. Sharp's contention. Mr. Kesteven takes Mr. Sharp's excuses one by one and pulverises them, and "A Hospital Surgeon" thinks it is unreasonable for the School Board to insist on poor parents obtaining a certificate. It is curious how widespread is the delusion that the Board demands certificates. *It never does*; the only people who demand certificates are the magistrates. So the Board says, and yet it has a printed form of its own for a medical certificate. We have fought this question of certificates ever since June 8th, and now that our powerful contemporary has opened its columns to the matter we hope to see Mr. Sharp and his committee retire from their untenable position.

THE SCHEME OF SEA-WATER SERVICE SUPPLY TO LONDON.

ON reflection the idea of bringing a supply of sea water into the metropolis opens some very interesting and important possibilities from a public health as well as from an economic point of view. That the project is no mere dream is evident from the fact that a Bill is being prepared for presentation in the next session of Parliament for powers to provide London with a supply of sea water direct from the south coast, near Lancing, in Sussex. Were the scheme sufficiently comprehensive, it is probable that its application would affect the question of London's future water-supply. It seems to us that if sea water could be substituted for fresh water for the purpose of flushing our drain and sewer systems, a very important economy in the supply of water for drinking purposes would result. The amount of water used for merely removing waste and offensive matters from our midst is, in proportion to that used for consumption, very considerable, and the demands, therefore, for potable water as London's first necessity of life would be very materially reduced. Assuming, for example, that each individual uses two gallons of water for flushing purposes per diem, this alone would mean a saving for the drinking supply in London of at least 10,000,000 gallons a day if sea water were substituted for this purpose. Is there, then, any necessity to go further afield, as, for example, to Wales, for an additional supply of water for drinking purposes, and to incur such enormous expense, when within fifty miles of the metropolitan area sea water may be had in inexhaustible quantity, the equivalent of

Digitized by Google

which would be saved for drinking, cooking, and cleansing purposes? On the face of it, it is an absurd piece of extravagance that the same water which we drink, and which, therefore, is purified with great care, should be used for the mere conveyance of sewage, and thereby immediately grossly contaminated. Further, it is also evident that, if sea water were used in our sewers, an important aid to the detection of sewage contamination of water-supplies and to the establishment of leakage would be afforded, since obviously a preponderance of saline matter could be easily ascertained by chemical analysis, which would decide the question of pollution. Again, sea water serves to arrest the putrefactive processes for a time, and acts very prejudicially on the germ of typhoid fever, so that it is probable that the offensive and unhealthy character of sewer emanations would be favourably modified. All these are facts which should lead us to consider the scheme of sea-water supply to the metropolis with very great care, for the proposal has, we venture to think, a much more important bearing on public affairs and London's future history than at first sight appears.

ENLARGEMENT OF THE CHALFONT COLONY FOR EPILEPTICS.

ON Tuesday last a new home to accommodate eighteen male epileptics was formally opened by the Duke and Duchess of Devonshire. The cost of erecting the home has been defrayed by Mr. Passmore Edwards, and it will be called by his name; and it was announced that he has also generously undertaken the erection at his own expense of a home and school for epileptic children. The committee have already in hand the addition of a home to accommodate a score of epileptic women, and a laundry in which they may be employed, so that it will be seen that the scheme has already passed the experimental stage; and the satisfactory results obtained, and the number of applicants still awaiting admission, indicate that further extension of the operations of the society will be required before long. The colony was opened in July, 1894, with nine colonists. In August of this year the committee were able to take thirty-six, and it is probable that by this time next year the numbers will be doubled. The colonists have been employed mainly at market gardening, and a few of them at occupations, such as carpentering, which they followed before their admission. Lack of funds has up to the present hindered the provision of other employments such as basket-making, netting, rope-making, &c., which will provide more variety and allow more scope for differences of capacity on the part of individual colonists. Hitherto there has been no medical man resident at the colony, but the committee have most prudently determined to erect a building for a resident medical officer, with a residence of such a character that patients of a superior class may be taken, whose payments at a higher rate may cover the extra cost to the colony. No one who knows anything of the accidents, the occasional explosive outbursts of mental excitement which are sure to arise from time to time in such an institution, will question the urgent necessity of having a medical officer of experience on the spot. The medical reports on the working of the colony show that with improvement in the colonists' surroundings there has not only been extraordinary improvement in their physical health, but a definite amelioration of the disease—fits have been less frequent and less severe in almost all cases, and except in a few instances mental deterioration has been arrested. The healthy out-door life, abundance of plain food and fresh vegetables, and steady occupation have no doubt largely to do with the result; but we understand that in all cases the physicians have found it necessary to continue treatment by drugs. Not a single case of serious illness apart from epilepsy has occurred among the colonists. But to equip the colony properly a large amount of money must still be expended, and the constant expenditure for maintenance is a severe strain on the resources of the institution. We hope that the eloquence of the Duke of Devonshire and the example of Mr. Passmore Edwards will result in a most liberal response from the wealthy members of the community. We have often commended the enterprise in these columns as deserving of public confidence and support. The executive committee is composed not only of ladies and gentlemen well known for philanthropic enterprise, but also of such representative medical men as Sir James Crichton Browne, Sir William Broadbent, Dr. Buzzard, Dr. Ferrier, and Dr. Tooth; and the visiting physicians, Dr. Fletcher Beach, Dr. Colman, and Dr. Aldren Turner, are associated with the three hospitals in London at which special provision is made for epileptics. Able-bodied, sane epileptics are admitted if found medically suitable without distinctions of creed or locality. Forms of application can be obtained from the secretary, Mr. G. Penn Gaskell, National Society for the Employment of Epileptics, 12, Buckingham-street, Strand, W.C., to whom subscriptions can also be sent.

THE FRENCH SURGICAL CONGRESS.

WHEN towards the latter end of autumn the principal business meeting of a congress is fixed for 8 A.M. on the morning succeeding a banquet it is scarcely to be wondered if the attendance should be scanty. The general assembly of the French Association of Surgery took place under these prohibitive conditions, and so fatal was their influence that when the officials put in an appearance half an hour after the appointed time only fifty-two members out of a possible 300 were present to inaugurate the proceedings. As may be supposed, such unbridled somnolence on the part of the staff gave rise to a good deal of criticism, more or less serious. One very well-known and witty commentator began by frankly confessing that at the unearthly hour selected for the reunion all self-respecting Parisians were still snug in bed, and then gravely went on to remind the secretarial sluggards that punctuality is the politeness of kings. Now, of course, the ancient apophthegm may be perfectly germane in such a connexion with our neighbours on the other side of the silver streak, for is there not another ancient adage regarding the better management of things in France? Far be it from us to so much as hint that the Gallic organisers of congressional functions are not the monarchs of all they survey; but assuredly their congeners with us could never justify so regal a simile, being unfortunately more akin to slaves than sovereigns—in fact, an army of veritable martyrs to science. The subject, however, is too knotty to be discussed within reasonable limits, and, moreover, the Congress demands attention. Two candidates for the presidentship, MM. Terrier and Le Dentu, having obtained 27 and 25 votes respectively, the latter withdrew from the contest, whereupon M. Terrier was elected almost unanimously. The vice-presidency fell to Professor Gross of Nancy, M. Broca remains treasurer, and the joint secretaries are MM. Baudouin, Mauclaire, Coudray, and Reblaud. The financial position of the Congress was shown to be most flourishing, so much so, indeed, that for the future the transactions are to be produced independently instead of being, as heretofore, entrusted to an outside publisher. The business proceedings ended, Professor Bousquet of Clermont-Ferrand proposed in his own name, as well as on behalf of several leading members, that general meetings should always be held in the afternoon; but apparently all power is in the hands of the Conseil d'Administration, and no decision was arrived at. Professor Bousquet also drew attention to the

Digitized by Google

unsympathetic attitude of the Parisian hospital surgeons towards the members of the Congress. In no case did they offer the slightest encouragement to strangers to attend their operations or visit their wards. The general secretary replied that the above complaint was fully justified. He had done his best to remedy the defect, but, unfortunately, could not succeed. When a visitor arrived at New York and manifested a desire to witness operations the utmost *empressement* was exhibited to afford him every information by telegraph. No matter where he might be sojourning, every morning messages would arrive containing detailed statements of all the operations it was proposed to perform that day, together with time-tables and route instructions. It would be very easy for the Parisian surgeons to imitate their New York *confrères*, and thus remove the grievance to which Professor Bousquet alluded. All that was necessary was a little goodwill, but, unfortunately, that was precisely what was not forthcoming. Possibly these gentlemen had very good reasons for their apparent churlishness, but if so it was strange that similar reasons should be non-existent across the Atlantic. The banquet the previous evening, notwithstanding its alleged absentee-producing effects, seems to have been rather a dull affair. The chairman, M. Eugène Boeckel, presided with effect; M. Delorme returned thanks for the army medical officers; M. Demons for the provincials; and Professor Jonnesco pronounced a discourse wherein he dwelt upon the intimate scientific union which exists between Roumania and France. "I have mentioned Roumanian surgery," exclaimed the enthusiastic delegate; "but I should rather have said French surgery in Roumania. Living at the gate of the Orient, we are all of us the indefatigable pioneers of French science and French civilisation." Finally, M. Monod proposed the health of the organisers of both Congress and banquet, and M. Picqué having responded briefly the proceedings terminated. The commentator already alluded to[1] concludes his article in the following words: "The reunion struck us as being a little colder than usual; perhaps we should try to find something more novel than a banquet. Is this impossible? We do not think so. We are not altogether destitute of ideas on the subject, but first of all it must appear whether or no a change is desired."

PRIMITIVE MAN.

AT a special meeting of the Anthropological Institute held at 3, Hanover-square, on Monday evening, Nov. 25th, Dr. Eugène Dubois from Holland read a paper describing his explorations in Java, and gave a demonstration of the interesting fossil remains discovered by him during six years' residence there. Most attention was attracted by the remains of a human-like femur, an anthropoid skull, and two molar teeth found alongside various extinct species in a pliocene stratum on the banks of a river in Java. As these specimens were found within an area of fifteen metres, Dr. Dubois considers that they all belong to one skeleton. He holds that these form the strongest evidence yet adduced in favour of the doctrine of man's progressive development along with the apes from a common progenitor, for he asserts that these indicate a transitional and intermediary form between man and the anthropoid ape, a creature measuring about five feet and a half in height, maintaining an erect posture, to which he has given the name Pithecanthropus erectus. The individual bones have given rise to much discussion in the scientific world since Dr. Dubois published a short monograph some months ago describing the find, and on Monday evening he related the various divergent opinions held by authorities who have examined the specimens. The femur presents all the characteristics of a human thigh-bone, and, strange to say, shows rare pathological changes, myositis ossificans having affected the insertions of muscles on the upper third of the shaft. Dr. Dubois, however, thinks that he discerns some distinctive features, especially in the popliteal surface; this triangular space between the divergent supra-condylar lines is seen to be convex instead of being flat as in the human bone. Some of the anatomical authorities hold that this apearance is the result of the pathological process. Whatever difference of opinion exists regarding the femur, the skull is quite unique, and approaches more nearly the simian type than the famous Neanderthal skull, being much more ape-like in the sinciput, the supra-orbital ridges being very prominent, with a marked flattening over the frontal bones; but, on the other hand, its larger cranial capacity of about 1000 c.c. places it higher in the scale than any of the known anthropoid apes. The teeth, the distinguished lecturer maintained, belong to the skull and are very human-like in appearance, but the wearing away of the surface of the crowns points more towards the ape than to Homo sapiens. After the demonstration many distinguished zoologists and anatomists took part in the discussion, including Sir William Flower, Sir John Lubbock, Sir William Turner, Professor Thomson, Dr. Garson, Mr. Sutton, Dr. Keith, and others. If Dr. Dubois' thesis be adopted that these specimens belong to the same individual, then we are bound to admit the existence at an early period of an ape more anthropoid, or a man more pithecoid, than any remains have hitherto revealed, thus constituting an important link in tracing man back to an early form, which probably existed in the Archipithecus in the eocene or pliocene periods, whence he became differentiated from the simians, gorillas, &c. If, on the other hand, the bones belong to two individuals, then we have evidence of man being contemporaneous with an ape at a very early period having a skull more resembling his own in form and capacity than any now existing. The truly scientific attitude is to wait for further researches by the palæontologists before we attempt to formulate our opinions.

[1] Dr. Marcel Baudouin, secretary of Le Progrès Médical.

REDUCTION OF AN INVERTED UTERUS AFTER FIVE DAYS.

IN the New York *Medical Record* of Oct. 26th is a very complete and interesting account of a case of inversion of the uterus of five days' standing and of its successful reduction. The patient was twenty-eight years old, a primipara, and was delivered with forceps after a labour of about eighteen hours. The extreme rarity of this accident leads us to give a few particulars. The perineum and vagina were much torn, and the removal of the placenta was followed by severe hæmorrhage. After the physician had left for a distant place pelvic pain and symptoms of collapse appeared, and a neighbouring physician did what he could to help the patient through the night. The next day fever and retention of urine occurred. The catheter was used once. The following two or three days passed, with uterine pains and more or less temperature. On the fourth day the temperature was 103·4° F., and she again changed medical hands and came under the care of Dr. A. A. Davis. The symptoms were somewhat misleading. The face was pale and the expression anxious. There had been no sleep since delivery, and though there was no great pain there was restlessness. There was a tender swelling of the hypogastrium reaching to the umbilicus. As urine had passed in considerable quantities since catheterism on the second day it was concluded that this swelling was due to a hæmorrhage, but a vaginal examination was not made. The next day Dr. Davis proceeded to, as he thought, clear the uterus of clots, and, after forty-eight ounces of urine had been drawn off, came upon a mass which, but for

Digitized by Google

the hypogastric tumour, he would have considered inverted uterus. But after consultation with Dr. Pickard, and further catheterisation yielding fifty ounces more, it was easy to feel that there was no uterus in the abdomen, and the diagnosis of inverted uterus was confirmed by further vaginal examination. The tumour was the size of a child's head, just inside the vulva and completely filling the cavity. The surface was moist with lochial discharge of normal odour, covered here and there with films of coagula. As a mass the tumour was pale and anæmic from diminished blood-supply due to contraction of the cervix. Felt through the abdomen it seemed to be a hard and round surface in the pelvis, with no cupping of the cervix. Under etherisation the walls became soft and completely relaxed. The process of reduction was slow, and the steps of it are given with great and interesting detail. At the end of an hour Dr. Pickard's hand was so benumbed that he had to resign the work to Dr. Davis. It was noticed that under steady pressure from below, and with increasing dilatation of the cervix, the uterus was slowly returning itself, not by movement at the fundus, *but at the cervix, the tissues nearest the cervix returning first*. There was fear lest the patient, who was pale and apathetic at the beginning of the operation, should be unable to bear it, but she was as well at the end of it as at the beginning. For ten days after her state was very precarious. She then improved for some days. But after this she became worse, and rapidly sank from peritonitis and metritis about twenty-one days from the time of delivery. The case is full of lessons. Happily few practitioners see such cases. Braun states that of 250,000 births in the clinics under him and Spaeth, not a single complete inversion had come to their notice.

THE MEDICO-MILITARY ARRANGEMENTS OF THE JAPANESE ARMY.

WE have already alluded to the graphic report which Surgeon-Colonel Taylor has given of the medico-military arrangements of the Japanese army in the field during the War of 1894–5 between China and Japan. The progress which the Japanese have made during the last thirty or thirty-five years is remarkable. About that time ago very little indeed was known of Japan. Its people held little or no intercourse with other nations, and it was with some difficulty and only as a great favour that officers of our fleet were allowed to land and make themselves acquainted with the place and its people, and but few indeed of the Japanese had up to that time visited Europe. Things have entirely changed now. The Japanese have visited this and other countries, have made themselves well acquainted with modern arts and sciences, and have returned to their own country and applied all the knowledge they have acquired with wonderful skill and sagacity. Their bravery and patriotism, their aptitude for war, their capacity for organisation and administration, their patience and painstaking, and their mastery of detail are now well known and generally recognised. As far as their medical regulations and the application of the latest results of surgical science to war purposes went the Japanese were remarkably successful. The last thing which nations seem to learn, however, is that which is necessary to be known and put in practice everywhere and at all times—namely, the ordinary principles of sanitary science and practical hygiene. This was not to be wondered at, perhaps, as far as the Japanese are concerned, for it is only of recent years that this country has paid any regard to sanitation and the laws of health. Surgeon-Colonel Taylor in his report states that the Japanese had no regulations for ensuring satisfactory sanitary conditions, and that in practice the same want of thought of all sanitary precautions, even of the most ordinary kind, was evident. He gives several striking illustrations of this drawn from his own observations, and speaks of the universal indifference to the mos insanitary surroundings as incomprehensible, but as, nevertheless, an undeniable fact that existed at the beginning of the war and until very near the end of the campaign. The Japanese being an eminently practical and receptive people, however, learnt the vast importance of army sanitation before the campaign was over, and made strenuous exertions towards its close to improve existing conditions and introduce sanitary measures.

BOARD SCHOOLS: MANNERS AND ANATOMY.

BOARD schools exist, like the Apocrypha, for "example of life and instruction of manners," but their efforts are not always successful, as is apparent from the following story. A teacher in a Board school has been giving some girls instruction in elementary anatomy to point the evils of tight-lacing. Thereupon she received the following letter from the mother of one of her hearers: "Dear Miss ——,—Please don't tell our Lizzie anything more about her inside. It is not nice, and frightens her. Besides, it's rude." Tight-lacing is nowadays almost a thing of the past since athletics have come to form so large a portion of women's amusements, but anatomy and common-sense are alike powerless against the dictates of fashion. If fashion decreed that, instead of wearing the products of diseased molluscs in their ears, women ought to carry bones through their noses or discs of wood in their lips they would do it. A light, well-fitting, and yielding corset is almost a necessity, and it is only the more silly of the fair sex who enclose themselves in an iron grip.

A NEW METHOD OF STAINING FLAGELLA.

LÖFFLER'S method of staining flagella is probably the one most commonly employed. It is, however, rather troublesome and the manipulation required difficult. Dr. Pitfield of Philadelphia has introduced a new and easier one.[1] It consists in the use of but a single solution, which is at once mordant and stain. The solution should be made in two parts, which are filtered and mixed—(*a*) saturated solution of alum, 10 c.cm., and saturated alcoholic solution of gentian violet, 1 c.cm.; and (*b*) tannic acid, 1 grm., and distilled water, 10 c.cm. The solutions should be made with cold water, and immediately after mixing the stain is ready for use. The cover-slip is to be carefully cleaned, the grease being burned off in a flame, and after it has cooled the bacteria are spread upon it well diluted in water, care being taken to exclude culture medium. After the preparation has been thoroughly dried in the air it should be held over the flame with the fingers, as Löffler has directed. Afterwards the stain is gradually poured on the slip and heated gently, the fluid being brought almost to boiling point; the slip covered with the hot stain should then be laid aside for one minute, washed in water, and mounted. Upon examination the bacteria, both isolated and in clumps, will, if mobile, be found to have the flagella clearly and delicately defined. In the middle of the cover-slip, as well as round the edges, the bacteria will be found equally well stained, the clumps being surrounded by a zone of delicate fringing flagella, each being well stained and distinctly outlined from its fellows. If a clear preparation is desired, the stain, after mixing, may be filtered; but Dr. Pitfield has found that the most reliable method is to use the unfiltered stain. In the case of the former a clear fluid is produced without the detritus &c. being precipitated on the glass around the micro-organisms, and all the flagella are stained, but not so distinctly as with the unfiltered solution. If the filtered stain is used a second stain of aniline water containing gentian

[1] Medical News, Philadelphia, No. 10, vol. lxvii.

Digitized by Google

violet had better be used, which should be applied but a moment and then washed off, thus leaving a clean field, showing only the bacteria lightly stained, with their flagella still more lightly coloured. In examining the different bacteria Dr. Pitfield found that the bacillus of typhoid fever, the colon bacillus, the cholera bacillus, and the bacillus of hog cholera each stained well by this method and without the addition of any acid or alkali to the mordant such as Löffler uses. The bacillus of typhoid fever showed the flagella most beautifully, and there seemed one flagellum to each cell that stained more deeply than the others and appeared larger and stronger.

CHARING-CROSS HOSPITAL MEDICAL SOCIETY.

WE are glad to notice that the Charing-cross Hospital Medical Society, which for several years has been allowed to drop into unmerited obscurity, has been set on foot once more with every prospect of a successful session before it. The first meeting was held on the 20th inst., when several members of the school and hospital staff and a large number of students were present to listen to an instructive paper on the Abuse of Athletics by Mr. C. D. Francis Burney. An interesting discussion followed the reading of this paper, in which Dr. F. W. Mott, Dr. M. S. Pembrey, Mr. Morgan, Mr. Carter-Braine, and others took part. Mr. Burney replied in suitable terms. A vote of thanks to the chairman, Mr. C. Gibbs, F.R.C.S. Eng., brought the proceedings to a close. These meetings are to be continued once a fortnight throughout the winter session, and it is hoped that every student of the hospital will take the opportunity of attending what is likely to be a very instructive and helpful course.

THE UNQUALIFIED ASSISTANT.

AT an inquest held on Nov. 8th by Dr. Wynn Westcott at the Shoreditch Coroner's Court, a special verdict was given with reference to the employment of an unqualified assistant at a branch practice. The deceased was an infant who had been in good health till Nov. 1st. The mother took him next day to Mr. Currah's surgery at 92, St. John's-road, Hoxton, and there saw a gentleman whom she supposed to be a qualified medical practitioner. He prescribed a powder which was duly administered, and on Nov. 4th he prescribed a powder and mixture. At a late hour on that day the patient became worse and the mother returned to the surgery, but it was closed, and no one was resident there. Another medical man was sent for and came at once, but the child died before his arrival; he made a post-mortem examination and gave evidence at the inquest that the cause of death was croupous pneumonia of both lungs, and that the body was well nourished and free from signs of injury. The evidence of the prescriber was as follows: "I am employed by Dr. Currah. I am a dispenser of medicine. The mother came to me on Saturday morning, and I gave her a powder; she came again on Monday, and I gave her a mixture of ipecacuanha and ammonia. ..... I have no legal qualifications. Dr. Currah's name is on the door; he lives close by; neither of us lives on the premises. ..... I have been twenty years an unqualified practitioner, and it is very hard to be prevented from practising." The jury returned a verdict of "Death from acute pneumonia," adding an emphatic expression of opinion that unqualified men should not be permitted to prescribe and dispense as qualified men. So far the case does not materially differ from many which are from time to time recorded, and which have occasionally proved a source of trouble to the legally qualified associate in the business. The employment of unqualified assistants is not unlawful, and under proper supervision their services may be not only useful to their principals but advantageous to themselves, as for instance when they happen to be young men on the point of entering the profession. Mr. Currah, however, in seeking to justify himself, gave the matter an entirely new and reprehensible aspect. His evidence was as follows: "I am a registered medical practitioner; I have a branch practice at 92, St. John's-road; I employ Mr. [illegible] to dispense there and prescribe for trifling cases; I am frequently there. He is told to call me whenever necessary. An unqualified man takes less wages; and unqualified men are better than some young qualified men; but a person who pays only sixpence for medical attendance does not expect to have medical attendance from a qualified man." Mr. Currah's remarks were probably made in haste, and intended only for the limited audience of a coroner's court in a poor neighbourhood; on further consideration must satisfy him that they will stir of a highly unfavourable interpretation. His suggestion that the efficiency of medical services, by whomsoever rendered, may be estimated according to the fee paid by the patient is one which cannot be too promptly and strenuously repudiated.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT the recent clinical examination for the Fellowship a number of interesting cases were brought together, and, as usual, many Fellows of the College attended in order to see them. The cases provided for these clinical examinations for the Fellowship form the best collections of clinical cases to be seen in London, for patients presenting surgical conditions typical or rare are sent from all the London hospitals. In fact, it is probable that nowhere else in the world can such an assemblage of remarkable cases be seen. The clinical examinations, like all the other examinations of the College, are open to all the Fellows. Of course, it must happen that great variations occur in the value of the cases shown, and on this occasion they were not quite up to the average. Two of the cases deserve mention. One was that of a little girl, eight years of age, with congenital absence of tibiæ, but she was able to "walk" fairly on the ends of the femora; as in all these cases, the fibulæ were hypertrophied. The other case was that of an infant with a translucent fluctuating swelling over the right parietal bone; it appeared after an injury, and was probably what has been called a "traumatic meningocele" or a "cephalhydrocele"; in this case there was no pulsation.

JURIES AND OVERLAYING.

THE commendable zeal shown by coroners in dealing with cases of overlaying is clearly of little practical value unless it be supported by the intelligence and good sense of their jurymen. Unfortunately for the public interest it is not always thus aided. In order to prove this we need only refer to an incident which lately occurred in the Lambeth Court. The case was that of a woman, the mother of four children of whom two had died in succession from being overlain. At the examination on the first occasion the woman had been carefully warned against having a young child in bed with her. She had nevertheless persisted in this practice, and another death within twelve months was the result. Mr. Braxton Hicks pointed out these facts to his jury. He also informed them that 500 children had in this way been done to death during the last ten months in London alone. What was then the decision of these twelve interpreters of justice? Accidental death, purely accidental. Well might the coroner describe the process of legal inquiry under such irrational direction as a "perfect farce." After the warning conveyed to this mother and impressed by experience on a former occasion, the least that was compatible with sound judgment or consicence in a matter of public duty was a verdict of neglect. It is impossible even

Digitized by Google

to allege in excuse the difficulty of providing separate sleeping accommodation for a young child. A box and a couple of chairs will suffice for an extemporised cot. Such means are daily used for this purpose among the intelligent poor, and if the ignorant or the careless do not regard them this fact only adds force to our argument. The mother in the case quoted was not ignorant. She was thoughtless and negligent, and the only possible decision respecting her conduct was one which would so describe it. It is to be hoped that coroners' juries in future will not be so deceived as to confirm a verdict which in its feeble pity for the heedless parent is so cruel towards the child. It is to the loyal exercise of a sound and simple judgment in such matters that we must look if we desire to avoid the necessity for special legislation in cases of this kind. Unless the exercise of this faculty can be relied upon, as it ought to be wherever twelve rational persons meet together, we can see no other alternative but to include the "accident" of overlaying within the list of indictable offences.

A HUMANE POLICE CLUB.

FROM America comes an account of a new weapon for the use of the police. To quote from the descriptive pamphlet, "it is strong and effective, safe, humane, and nearly indestructible. In its use the human brain is not injured, the normal skull fractured, the skin broken, nor blood brought except at the nose. It may break an arm or blacken an eye. Experiments on cadavers, animals, and violators of the law confirm these claims. It stuns and stupefies temporarily, with rapid and complete recovery. Such claims cannot be made for any other effective police club. This policeman's club is 'composed of a central core-piece and an elastic envelope constructed in an integral piece and wholly enclosing said core.'" A variety of testimonials appear in the pamphlet, from which we select the following as being simple and as throwing a new light upon the way in which the supply of police is kept up: "Glasgow, Scotland, April 1st, 1895. I will put it into the hands of an experienced officer for trial. What do you charge for them?" The club is the invention of a Dr. Nelson, who claims for it that its use will stun a man without doing him permanent injury. Successful experiments appear to have been made upon dogs and calves, but though doubtless it would not cut like a wooden club we doubt whether the concussion effects would be any less than when the old club is used.

QUININE AS A PROPHYLACTIC OF INFLUENZA.

DR. C. GRAESER of the German Hospital at Naples points out[1] that the timely and continuous administration of quinine during influenza epidemics may undoubtedly prevent infection, and cites in support of this opinion—in holding which he does not stand alone—his experiences with regard to a regiment of hussars stationed at Bonn during the epidemic wave of 1889–90. He has previously published these facts, but again refers to them in consequence of an article which appeared this year in a Paris medical journal,[2] stating that experiments on rabbits showed quinine to be inactive against the infection of influenza. His facts are simply these: that for a period of twenty-two days he administered to each man of one of the squadrons of the regiment 0·5 gramme — i.e., about 8 grains — of quinine hydrochlorate, and that the numbers attacked by influenza in this squadron were far smaller than those who succumbed in each of the other squadrons, even in those occupying the same quarters. Thus, during this period there were attacked in the first squadron twenty-two men, in the second seven, in the third nineteen, in the fourth forty-two, and in the fifth thirty-two. Now it was the second squadron that underwent the quinine treatment, and of the seven men attacked three fell ill on the first day of the trial, two on the third day, and one on the fourth and fifth days respectively. After that no cases arose in this squadron, although fresh attacks continued to occur in other detachments. Dr. Graeser is persuaded that this *experimentum crucis* justifies the conclusion that quinine has a specific action in influenza, and that when administered at the appropriate time and in sufficient dose it may prevent an attack in a person exposed to infection. Such an experience, he holds, is of more weight than any experimental results in animals.

THE HUXLEY MEMORIAL.

ALTHOUGH Professor Huxley's life and work have so stamped his personality upon the nation that he will never be forgotten, yet it is fitting that some tangible memorial of so great a mind and so charming an individuality should be established. On Nov. 28th the general committee appointed to further such a memorial met in the Museum of Practical Geology. Literature, art, and science were all represented, and it was decided that the memorial should take the form of (1) a statue to be placed in the Natural History Museum; (2) a medal in connexion with the Royal College of Science; and (3) that the surplus should be devoted to the furtherance of biological science, the manner to be determined by the committee, dependent upon the amount collected. It was also announced that Messrs. Macmillan were prepared to publish at their own risk a collected edition of Professor Huxley's scientific papers, and would defray the cost of editing. The total sum promised and received is £544.

METROPOLITAN HOSPITAL SUNDAY FUND.

ON Monday last, Nov. 25th, the Council of the Metropolitan Hospital Sunday Fund assembled in the Venetian Parlour of the Mansion House to determine the report of the Council for 1895, to revise the list of Council for the coming year, and to recommend a convenient day for the Hospital Sunday collection in 1896. As previously announced,[1] the twenty-third year of collecting the Fund has resulted under the presidency of the late Lord Mayor, Sir Joseph Renals, in an unprecedented total of over £60,000, and the report gives prominence to the Council's desire to place on record its indebtedness to the persons mentioned in a series of resolutions adopted at the last meeting of the Council. The large sum collected this year will, we hope, be always maintained, if not exceeded, and the auspicious words with which Colonel Sir Walter Wilkin, the new Lord Mayor—who by virtue of his office presided at the Council meeting on Monday as President of the Fund—give us every reason to believe that such will be the case. "I am very gratified indeed," he said, "to find that the amount realised this year has reached so large a sum, and I trust that during the coming year you will assist me, and I will do all I possibly can, to at least maintain these figures." Hospital Sunday in the metropolis has always been fixed as near as possible to the middle of June, and in accordance with this precedent the next annual general meeting of the Fund will be asked to sanction June 14th as the date for Hospital Sunday, 1896. To fill the vacancies on the Council caused by death or resignation the following names are recommended: The Rev. Canon Graham, the Rev. David Anderson, the Rev. M. R. Neligan, the Rev. H. Russell Wakefield, Sir Joseph Renals, Bart., the Earl of Stamford, Alderman Faudel Phillips, and Mr. John Astley Bloxam, F.R.C.S. Eng. During the proceedings some discussion took place on a question raised by Mr. Acland with reference to the position

[1] THE LANCET, Nov. 16th, p. 1248.

Digitized by Google

of St. Thomas's Hospital in regard to the Fund and its non-participation in the awards. The matter will be fully discussed at a meeting of the constituents in the early part of next year. The annual general meeting will be held at the Mansion House, on Wednesday, Dec. 18th, at 3 P.M.

THE BATTLE OF THE CLUBS.

WE published last week a letter from Dr. T. Frederick Pearse, honorary secretary of the Portsmouth Medical Society, stating that the present holder of certain clubs at Portsmouth having refused to undertake the care of infants and girl juveniles under a charge of 4*s*. per annum, four medical men from other places had tendered for the clubs at a lower figure. The local members of the profession stood solidly by the holder of the clubs, refusing to compete against him by accepting lower terms, and we rejoice to say that the tactics of unanimity have prevailed. The present holder is confirmed in his appointment by 168 votes against 65, 31, and 11 given for the three outside competitors.

THE CASE OF DR. WIGHT.

As our readers are probably aware, the trial of Dr. Wight at the Central Criminal Court, on an indictment charging him with the manslaughter of Mrs. Fletcher by alleged unskilful treatment, took place on Monday and Tuesday of the present week, and resulted in a verdict of "Guilty" and a sentence of three months' imprisonment without hard labour. Medical evidence was given by Mr. Hannah after the verdict, but before sentence was passed, that the prisoner's health had been failing for some time, and Mr. Hannah is reported as having said that he did not think the prisoner was in his right mind. This evidence appears to us an important feature in the case, and, indeed, it seems to have been so considered by the judge, for he ordered that the prisoner should be placed under the care of the medical officer of the prison till the directions of the Secretary of State were received. Of course, if the medical opinion above mentioned as to the state of Dr. Wight's mind is correctly reported, and if this opinion should be corroborated, it is unfortunate that it should not have been produced for the consideration of the jury before they gave their verdict. Dr. Wight would in such case appear to have been entitled to an acquittal on account of the state of his mind. Most probably the Home Secretary, under the circumstances, will obtain independent medical opinions in this matter before deciding whether or not the sentence pronounced shall be carried into effect, and we feel sure that everything that is submitted to him on this aspect of the matter will receive the consideration it deserves.

THE RELATION BETWEEN ADENOIDS AND TUBERCULOUS CERVICAL GLANDS.

AN interesting pamphlet has recently been published by Dr. J. H. Nicoll of Glasgow giving his impressions derived from a study of 500 cases of enlarged glands of the neck. Some of his conclusions are rather startling and so far opposed to received teaching that he would have made his paper more convincing if he had entered with greater detail into a consideration of the facts which led him to his conclusions and given a description of the methods of investigation pursued by him. He believes that caries of the teeth no more affects the glands of the neck than caries of the tarsus affects the glands of the groin. He admits that cutaneous eruptions cause enlargement of the glands, but that they are never tuberculous. Chronic enlargement of the cervical glands he believes to be due in 80 per cent. of the cases to tuberculous infection from the tonsils and naso-pharyngeal mucous membrane. On this ground he practises and enthusiastically recommends the removal of the tonsils and erasion of the naso-pharyngeal mucous membrane whether there be enlargement of the tonsils and adenoid vegetations or not, as a preliminary to excision of the glands. He maintains that in most tonsils removed in this way tubercle bacilli may be discovered under the microscope even when there is no evidence of tuberculous disease to the naked eye. No drawings of sections are given, and we are often obliged to rely on the dogmatic assertions of the writer instead of being able to consider the evidence on which he has arrived at his conclusions.

THE INCONSISTENCIES OF ANTI-VIVISECTIONISTS.

MR. BURFORD RAWLINGS, in a letter to the *Times* of Nov. 27th, points out with great force the injury which the unreasoning and illogical attitude of the anti-vivisection clique is inflicting upon hospitals. Mr. Rawlings quotes a list of "bequests to societies amounting to some £60,000, of which the large majority were for the benefit of animals other than man—horses, dogs, &c.—while the institutions which are supreme in their beneficence and utility were conspicuously absent. The explanation was found in a legacy of large amount bequeathed to an 'anti-vivisection society,' and, without for a moment seeking to lessen the full liberty of a testator, hospital workers may be permitted a protest when they believe the exclusion of their institutions is brought about by reckless mis-statement. The animus exhibited in the provisions of this particular will is remarkable chiefly because of its increasing frequency, and we may well ask what is the result these assailants of our hospitals have set themselves to achieve." Whatever be the result they wanted to achieve, the one which they actually do achieve is to lessen the number and amount of subscriptions, and so compel the closing of wards. Mr. Rawlings points out the inconsistency of members of anti-vivisection societies who, when ill, at once employ a medical man and a nurse, both of whom have been trained in an institution which the sick man has been in the habit of vilifying both by word and action. We take it that the most bigoted anti-vivisectionist, if he had an aneurysm or a wound in an artery and was told that he could be cured by the ligation of the vessel, would submit, and yet the feasibility of such procedure was established by experiment on the living animal. Hospitals, as the writer of the letter we comment on says, are not responsible for the practice of vivisection, and it is equally cruel and foolish of the opponents of that practice to try to make them so.

A SESSIONAL meeting of the Sanitary Institute will be held at the Parkes Museum on Wednesday, Dec. 11th, at 8 P.M., when Sir Douglas Galton, Vice-President of the society, will open a discussion on the Lessons to be Learned from the Experimental Investigations by the State Board Health of Massachusetts upon the Purification of Sewage.

LUCKLESS Christ's Hospital! There are now under treatment in the infirmary of the school cases of measles, scarlet fever, and diphtheria, and the parents of the boys have, we understand, been informed that they can remove their sons if they wish to do so, and can do it without risk to other members of the family, before the end of the term.

"INFECTIVE and Tubercular Osteitis as Causes of Arthritis, and the Importance of their Early Treatment" is the title of the Bradshaw Lecture to be delivered at the Royal College of Surgeons of England on Dec. 5th at 5 P.M. by Mr. C. N Macnamara.

THE Milroy Lecturer at the Royal College of Physicians of London for 1896 will be Dr. Edward Seaton.

Digitized by Google

LORD KELVIN is to retire from the Presidency of the Royal Society, and Sir Joseph Lister has been nominated as his successor. Sir Joseph Lister will be the first practising surgeon who for many years has occupied this exalted position, and the profession will join us in heartily congratulating him upon his merited attainment thereto.

THE Harveian Lectures on "The Heart in its relation to Pregnancy, Parturition, and the Puerperal State" will be delivered before the Harveian Society by Dr. M. Handfield-Jones, on Dec. 5th, 12th, and 19th, at 8.30 P.M., at the Stafford Rooms, Tichborne-street, Edgware-road, W.

DEPUTY-INSPECTOR-GENERAL RICHARD DOMENICHETTI has been appointed Honorary Physician to Her Majesty the Queen; and Surgeon-Major-General C. D. Madden and Surgeon-General H. T. Reade, V.C., C.B., have been appointed Honorary Surgeons to Her Majesty.

HIS ROYAL HIGHNESS THE PRINCE OF WALES has promised to take the chair at the festival dinner in aid of the funds of Guy's Hospital, which is announced to take place in May next.

ABUSE OF MEDICAL CHARITIES.[1]

BY C. A. GRIFFITHS, F.R.C.S. ENG.,
LATE RESIDENT MEDICAL OFFICER, GENERAL AND EYE HOSPITAL, SWANSEA;
AND
T. G. HORDER, M.R.C.S. ENG., L.R.C.P. EDIN.,
EX-PRESIDENT, CARDIFF MEDICAL SOCIETY.

BEFORE referring to the inquiry we have made into the medical charities of Cardiff it may be as well briefly to state what has been done in reference to this question in other towns and also to refer to a Conference of the Charity Organisation Society which met at Oxford in the year 1890 and discussed the question of organisation of medical relief. From the report of the Medical Charities Committee of the British Medical Association which was presented to the members at the annual meeting held in Birmingham in 1890, we extract the following: "The committee recommend an immediate reform of the in-patient departments of medical charities as an urgent necessity, and would especially emphasise the fact that it is difficult fro provident or other thrift movements to compete successfully against medical charities which bestow relief on all applicants without any inquiry, or against those which, by charging a fee from 1*d.* to 2*d.*, try to undersell any provident system. They would also add that the reform of provident dispensaries and sick clubs is necessary." To carry out these proposals the committee consider that a reform of the abuse of the out-patients' departments would be best attained by some modification of the Manchester system, which is set out in the appendix. To this end they would recommend that the following "wage limit" should be adopted: single man or woman, 14*s.* per week; man and wife, 18*s.* per week, and 1*s.* 6*d.* for each child (19*s.* 6*d.*, 21*s.*, 22*s.* 6*d.*, 24*s.*, 25*s.* 6*d.*, 27*s.*, 28*s.* 6*d.*, 30*s.*, &c., per week). The above "wage limit" is one that cannot be adopted universally. On this basis they recommend that the following cases should be considered ineligible for outpatient hospital relief otherwise than as accident and urgency cases.

1. All those earning over the "wage limit." Letters of recommendation from subscribers to medical charities, Hospital Saturday and Sunday Funds, ought to carry no weight unless the person so recommended for relief conforms to the "wage limit" clause. No subscriber should be permitted to receive any benefits for himself or his household. Each subscriber who recommends an ineligible patient should have forwarded to him by the hospital clerk or secretary a form like the following:—

SALFORD ROYAL HOSPITAL.

Name .....
Residence .....

The circumstances of the above-named person recommended by you have been carefully inquired into, and it is found that he is not a proper case to be admitted as a patient of this charity.

To Mr. .....

Full particulars may be obtained at the hospital.

G. H. Larmuth, Secretary.

2. That all those who are in receipt of Poor-law relief and those who are members of friendly societies possessing a surgeon shall be ineligible for out-patient relief, except with a recommendation from the surgeon in attendance to show it is a case requiring consultation. To inquire into the social circumstances of applicants for relief an inquiry officer should be appointed at each hospital with a view to prevent the abuse of charity by improper objects, and a notice to this effect similar to that in use at the London Hospital should be placed in the waiting-halls. This will act as a deterrent to those who try to impose on charity, and will therefore lessen the work of the inspector.

Notice to Governors and Patients.

1. With a view to prevent the abuse of charity by improper objects a waiting-hall inspector will be employed to ascertain whether any patients presenting governors' letters are able to pay the fees of consulting physicians or surgeons or (not being urgent cases) of local practitioners; or should be referred to recognised provident institutions (wherever existing) or being in receipt of parish relief should be required to attend Poor-law dispensaries.

2. In order to ensure that renewed attendance is granted solely to such patients as require the continuous advice of experienced hospital physicians or surgeons, a governor's letter will not entitle to more than one attendance unless the medical or surgical officer on duty may decide to prolong such attendance, and he is not at liberty to continue in force any ticket unless in his professional opinion further treatment be necessary or desirable, in which latter case attendance may be prolonged without renewal.

[The Manchester Royal Infirmary system for checking out-patient hospital abuse was then cited. This system consists, in brief, of the employment of an inquiry officer and a wage limit. Letters were then quoted from the hospitals of St. Bartholomew and the London, and the Manchester Royal Infirmary, stating their methods for checking abuse of the charity by out-patients. They all consisted in the employment of an inquiry officer.]

As to the organisation of medical relief, Mr. Timothy Holmes of London, in speaking on this subject at Oxford in 1890, made some valuable observations which are well worthy of attention.

[A portion of Mr. Holmes' paper was then quoted as well as some remarks of Mr. Smith of the Manchester and Salford District Provident Society.]

The result of much deliberation was the establishment of a number of provident dispensaries in various parts of Manchester and Salford, and a system of investigation into the circumstances of applicants for relief at the free medical charities. Those charities who fell in with the scheme abolished to a great extent the system of subscribers' recommends and agreed to treat all cases upon application. The names and addresses of the patients are then sent on to the District Provident Society, whose officers visited their homes and inquired into their circumstances; those who were found to be able to pay medical men's fees were refused further charitable relief, and those able to pay the provident dispensary charges were referred to these institutions for further treatment, whilst those whom it had been necessary to take into the hospital as in-patients were required to contribute according to their circumstances to the charity at which they were being treated. This may be said to be the system of medical relief now in vogue in Manchester and Salford, and although a few of the medical charities have not seen their way to become affiliated, still they have individually adopted some similar scheme of visitation and investigation, and have benefited much thereby. In 1875, when the system was first applied, the percentage of applicants to the affiliated medical charities who were found to be ineligible for free treatment, and who were in consequence referred to the provident dispensaries or told to engage private practitioners, was 43·32, in 1880 it was reduced to 14·76, in 1885 to 13·57, and in 1889 to 6·89.

[1] An abstract of a paper read at the meeting of the South Wales and Monmouthshire Branch of the British Medical Association on Nov. 19th, 1895.

Thus, as far as Manchester and Salford are concerned, it may now be said that the once oft-heard cry, "abuse of medical charities," is a thing of the past.

Having obtained the permission of the committee we visited the out-patient department of the Cardiff Infirmary on several occasions; in all, we interviewed 129 patients attending the medical, surgical, ophthalmic, and aural departments. At the request of the committee Mr. Munday was present at each visit. The particulars we endeavoured to obtain from the patients were: (1) name; (2) age; (3) address; (4) occupation; (5) income of family; (6) number of family at home; (7) nature and duration of illness; (8) amount paid for rent; and (9) name of employer. The answers given to us were recorded in a book at the time, and we wish particularly to say that any conclusions we have arrived at have been drawn from those answers. In several cases where we were of opinion that further information was desirable we sought for, and obtained, the assistance of the Cardiff Charity Organisation Society. Before giving details we wish to say that the secretary's attention is called to cases where the income of the patients is stated on their letters to be above the "wage limit" adopted by the committee. It is only right that you should be acquainted with the regulations which are printed on the back of the out-patients' letters.

[The Rules were then quoted.]

In connexion with the "wage limit" we are informed that in 1891 a committee was appointed to consider means for the better organisation of medical charities in Cardiff, and that this committee, which consisted of representatives of the infirmary, the provident dispensary, and the Charity Organisation Society, made the following report:—

A meeting of the Joint Committee for the Better Organisation of Medical Charities was held at the infirmary on Thursday, Aug. 13th, 1891, at 5 P.M. Present: Dr. Sheen (in the chair), Mr. Charles Thompson (representing the infirmary), Mr. T. H. Stephens (representing the provident dispensary), and Mr. H. M. Thompson (representing the Charity Organisation Society). The following recommendations were unanimously adopted:—

1. With a view to prevent the abuse of the charity by improper objects a paid officer should be appointed to inquire into the circumstances of out-patients presenting governors' letters and applying for medical relief.

2. That a "wage limit" for out-patients at the infirmary be adopted, the following being suggested as applicable to Cardiff: Single man or woman, 18*s.* per week; man and wife, 22*s*; and each child, 1*s.* 6*d.*; and that all applicants for out-door medical relief whose wages shall be found on investigation to be in excess of this limit (unless for special reasons it seems to the out-patient medical staff desirable to retain them as patients) shall be referred to the provident dispensary or refused attendance, as the case may be.

3. In order to insure that renewed attendance is granted only to such patients as require it a governor's letter will not entitle to more than one attendance, unless the out-patient medical officer for the day may think it desirable that further attendance should be given.

4. No person in receipt of parish relief or belonging to a club with medical attendance, or being a member of the provident dispensary, shall be deemed eligible for relief, except for the purpose of a consultation on the recommendation, in writing, by the respective medical officers.

5. Any domestic servant in service presenting an out-patient letter to be referred to the provident dispensary after one attendance.

6. That minor accidents and urgent cases be attended to in the first instance without inquiry, but referred to club doctor, provident dispensary, or private practitioner subsequently, as the case may be, if not eligible for treatment under the rules here suggested.

7. That a board should be placed in a conspicuous position containing the following information:—

GLAMORGANSHIRE AND MONMOUTHSHIRE INFIRMARY AND DISPENSARY.

This institution is a charity for the medical relief of the necessitous poor only.

Out-patient Department.

Patients are seen daily (Sundays excepted) at 3 P.M., on presentation of a governor's letter if they are suitable objects.

There are special departments for eye and ear cases and dentistry.

The ophthalmic surgeon attends on Monday, Wednesday, and Friday, at 3 P.M.

The dental surgeon attends on Tuesday and Friday, from 9 to 10 A.M.

Accidents and urgent cases are attended to at any time without a governor's letter.

Persons in receipt of parish relief, or belonging to a club with medical attendance, or to the provident dispensary, are inadmissible as out-patients, except on the recommendation of their respective medical officer for the purpose of consultation.

This report was presented to the infirmary committee on Oct. 14th, 1891, but was not evidently adopted as presented, for we find that the "wage limit" clause was altered, that the allowance for each child was altered from 1*s.* 6*d.* to 2*s.*, and, most important of all, that the recommendation of the committee to appoint an inquiry officer to investigate the circumstances of the out-patients was not carried out. We also found that the rule forbidding the treatment of persons receiving parish relief or belonging to clubs having medical officers has not been carried out. The growth of the out-patient department is worth recording, especially as we are given to understand that the infirmary is urgently in want of funds to enable the committee to open the new wards for in-patients. In the year 1885 the population of Cardiff was 97,034, and the number of out-patients was 7385. In 1895 (to June 30th) the population was 155,637, and the number of out-patients was 6455. It will be as well here to give the figures connected with the membership of the provident dispensary. In the year 1885 (ten months) the receipts from members were £277 6*s.* 10*d.* In 1894, with a membership of 1586, the receipts were £705 18*s.* 4*d.* On analysing those patients whose cases we had an opportunity of inquiring into we found that there were seven whose incomes amounted to 30*s.* per week, three to 31*s.*, two to 35*s.*, one to 38*s.*, one to 39*s.*, one to 48*s.*, two to 43*s.*, one to 49*s.*, one to 51*s.*, one to 74*s.*, and one to 58*s.* per week. That the condition of some of the patients should be better estimated we give particulars of those who were found to have a "wage limit" in excess of the infirmary standard, and also a list of those who, we have good grounds for believing, were in receipt of such an income as would not entitle them to charitable relief. The following cases appear to us from the statements made by the patients themselves to be outside the "wage limit" fixed by the infirmary committee:—

List I.

No.	Rent.	Income of family.	Number of children.
1	14/- (shop)	58/- (estimated)	Seven (two only not at work).
2	7/-	74/-	Six (three not at work).
3	4/6	51/-	Five (three at work).
4	6/-	48/-	Six (two at work).
5	7/-	43/-	Four (two at work).
6	10/-	43/-	Five (two at work).
7	5/6	51/-	Four (one at work).
8	4/-	35/-	None.
9	(?)	32/-	(?)
10	17/-	31/-	(?) One.
11	14/-	30/-	None.
12	7/-	30/-	Two (one at work).
13	5/6	38/-	Four (one at work).
14	5/6	30/-	Two.
15	6/-	32/-	Four.
16	10/-	(?) 30/-	Three.

= ¼ of the whole number examined.

In the following list are given the particulars of cases where we have good reasons for believing the wages stated by the patients to be below those usually earned by men of the same trade:—

List II.

No.	Trade.	Wages as stated.	Wages believed to be earned.
1	Coal trimmer	20/- to 40/-	40/-.
2	Marine engineer	£4 a month	£8 a month.
3	Hair-dresser	25/-	28/- (and commission).
4	Collier	7/-	(?) Average 30/-.
5	Tailor	12/- to 20/-	Much too low.

We have only to add that concerning all these cases we are in a position to give more information should it be desirable.

Turning our attention to the nature of the complaints for which the out-patients sought relief, we found that in a very large number of cases the illnesses were of a trivial nature, and such as could easily be relieved by a few bottles of medicine. We wish, however, to state that in some of the cases we could only make a shrewd guess as to the nature of the complaints; in the majority the nature of the illness had been diagnosed by the medical officers of the infirmary. The prevailing diseases were: anæmia, 11; disorders of the lungs (including cough, phthisis, and chronic bronchitis), 15; dyspepsia, 6; chronic rheumatism, 5; stomach disorders, 5; diseases of the skin, 5; and diseases of the eye, 18. The occupation of the patients or of their parents included the following: colliers, coal trimmers, warehousemen, tailors, boiler-makers and their assistants, marine engineers, hair-dressers, gardeners, masons, moulders, lodging-house keepers, outfitters,

Digitized by Google

bill-posters, policemen, dock pilots, publicans, fitters, dressmakers, domestic servants, and labourers. It was noted that there were several persons in the receipt of parish relief, some were in the receipt of club pay, and some were domestic servants in situations. In sixteen cases we were not able to ascertain the income of the patients and their families, and in eleven cases the heads of the families were out of work.

In summing up, we are decidedly of opinion—(1) that the "wage limit" at the Cardiff Infirmary is too high; (2) that a considerable number of persons obtain letters who could well afford to pay private practitioners; (3) that a very large number of persons obtain letters who could well afford to pay the small fees of the provident dispensary; (4) that a large proportion of the cases attending the out-patient department are of a very trivial nature and could easily be treated in other ways; and (5) that the only satisfactory way to discover these persons who are not entitled to receive the benefits of the charity is to appoint an inquiry officer whose sole duty it would be to make personal investigations into the circumstances of the patients after they have received one attendance. We think it right to state that patients seeking relief in the ophthalmic department can hardly be dealt with in the same way as patients in the medical and surgical departments. Some of those attending the ophthalmic department could very well afford to pay the fees of a specialist; but, on the other hand, it cannot be denied that the majority could not afford to pay those fees. It is difficult to suggest a remedy unless the ophthalmic surgeons could see their way to arrange to see patients on a certain day at their own houses at a reduced fee. We are given to understand that the ophthalmic surgeon at the infirmary has from time to time refused to attend certain out-patients, believing that they were well able to afford to pay the regular fees. From the very large number attending this department it must be almost impossible for the medical officers to make any sort of inquiry into the circumstances of those coming before them. We think that the appointment of an inquiry officer would tend to reduce very materially the number attending the ophthalmic department.

Through the courtesy of the committee of the Cardiff Provident Dispensary we were enabled to inspect the list of the members and to make any other inquiry we thought fit. This institution was established in 1884, and has an acting medical staff consisting now of eleven practitioners. The following is the number of patients on the roll for the years 1890 to 1894: 1890, 1517; 1891, 1482; 1892, 1456; 1893, 1547; and 1894, 1586. There is a "wage limit" for members, and it is as follows: Single man or woman, 21*s.*; married men, 25*s.*; each child, 2*s.*; and limit for man and wife and five children, 35*s.* The two points to which we directed our attention were: (1) whether persons were admitted as members who could reasonably be supposed to be able to pay the ordinary fees of private medical practitioners, and (2) whether systematic canvassing for members took place or not. We are satisfied that every possible precaution is taken to prevent well-to-do people becoming members.

With regard to canvassing for new members, we are informed that this takes place. It seems to us that medical men who are not on the staff have good grounds for objecting to canvassing. The chief cause of complaint to the lay medical aid associations is the fact that they canvass for members, and what is objectionable in a medical aid association must necessarily be objectionable in a provident dispensary. General practitioners who have no connexion with the dispensary are liable to lose patients. Such a system is apt to lead to reprisals on the part of private practitioners, and for this reason, if for no other, it should be dispensed with. We think with the committee of the dispensary that the sphere of usefulness of that institution might be considerably enlarged if the committee of the dispensary effected a closer alliance with the out-patient department of the infirmary. We have no hesitation in asserting that the vast majority of the out-patients we saw at the infirmary were in a position to afford the small subscription necessary for joining the dispensary. If ever such a close alliance came about it would be necessary, however, to increase the staff of the dispensary and also to establish subsidiary branches in the outlying districts. A model provident dispensary would be one that included on its staff every registered medical practitioner who had resided in the town for a period of twelve months, and who had been recommended by his brother practitioners already on the staff.

The *Hamadryad* Seamen's Hospital is supported by contributions from vessels belonging to the port. Patients are admitted on the order of their captains. In the case of foreign ships the Consul's order is also accepted. Sailors not belonging to the port are admitted on the payment of 3*s.* a day. Destitute sailors are frequently attended as out-patients without the production of an order. The order from the Consul or the captain is a contract that they will either contribute towards the hospital or pay 5*s.* a day during the period of treatment.

In conclusion, we think it right to state that the result of our inquiry merits the serious attention of the committee of the Cardiff Infirmary, and we feel sure that if they would only deal with the abuses which are pointed out they will have the support of all those people who believe that a charity like this should be restricted to the necessitous poor.

Cardiff, Nov. 18th, 1895.

AERIAL SPREAD OF DISEASE—IN CHANCERY.

AFTER occupying the Chancery Court for six days, an action heard by Mr. Justice Kekewich was concluded on the 20th inst. which, by its medical evidence, illustrates the still unsettled state of professional opinion as regards the aerial spread of small-pox, and which also illustrates the increasing difficulty which sanitary authorities have in finding an unopposed site for the erection of a small-pox isolation hospital, at least in the southern counties.

The Guildford, Godalming, and Woking Joint Hospital Board have at present provided a cottage, and propose to erect a small hospital with some ten or fifteen beds for small-pox, on Whitemoor Common in Surrey, where there is a population consisting of only 20 inhabitants living within a radius of a quarter of a mile, and a total of 103 within a half-mile radius of the hospital site. But some of the inhabitants around, headed by the owner of an estate whose mansion is just outside the half-mile radius, sought to obtain an injunction to restrain the combined Hospital Board from using the cottage or erecting a small-pox hospital there, on the ground that it would become a "nuisance" and a danger to themselves and their property. The hospital would be enclosed in about two acres of land, 100 yards across, and surrounded by a double wall enclosing a belt of trees. The site is surrounded on all sides by a common consisting of marshy ground which is utilised for the feeding of cattle and geese. Children are in the habit of playing on the common, and one of the plaintiffs keeps cows and earns his livelihood by selling milk and butter. Another is a market gardener whose house is about 170 yards from the proposed hospital, and others reside at distances of 200, 250, 335, and 450 yards.

There was an array of seven medical witnesses on each side, and the verdict practically turned on the scientific evidence for and against the theory of aerial convection. Dr. Thorne Thorne, Dr. Bruce Low, Dr. Alexander Collie, Dr. Russell, Dr. Morton, Dr. Wilson (Hastings), and Dr. Sanderson were subpœnaed by the plaintiffs.

Dr. Thorne Thorne, after protesting that it was not in the interests of the public service that he and Dr. Bruce Low should be called, gave evidence as to the danger of the proximity of a small-pox hospital. He expressed his firm conviction that the contagion of small-pox could be conveyed through the air in some way as yet undiscovered to a great distance—under certain circumstances to a distance of at least a mile. He admitted, however, that it was upon his advice, and explained on what grounds, that the Local Government Board had adopted the present regulations for sanctioning the sites of small-pox hospitals. In a letter to the Joint Hospital Board the Local Government Board had stated that it was not their practice to sanction any loan for the erection of a small-pox hospital which would have within a quarter of a mile of it 150 to 200 inhabitants, or within half a mile of it 500 to 600 inhabitants—numbers which largely exceeded the number of inhabitants around the proposed site.

Dr. Bruce Low gave similar evidence, and referred to the Hastings epidemic of 1894, in which he believed aerial convection played an important part.

Dr. Collie thought that the hospital grounds were not large enough. But in a long cross-examination by Mr. Cozens Hardy, Q.C., he would not commit himself to the view that small-pox could be spread through the air to any great distance. He admitted that the immunity of the Darenth Asylum adjacent to the small-pox camp, and other similar instances, were against that view, finally stating that isolation in his view meant the avoidance of corporeal contact. The plaintiffs' other medical witnesses supported the theory of aerial convection.

For the defendant board, Dr. Gayton, Dr. Savill, Dr. Orme Dudfield (whose evidence was taken on commission on

Digitized by Google

account of ill-health), Mr. Wellington Lake (the medical officer of health of Guildford), Mr. Collins (Kingston), Mr. Howlin (Woking), and Dr. Reginald Dudfield (Paddington) were called.

Dr. Gayton, after an experience of small-pox extending over nearly a quarter of a century in the hospitals of the Metropolitan Asylums Board, did not agree that a very large area around a hospital was necessary. He thought aerial convection was a theory which was not worthy of much practical consideration, and the facts on which it was based were capable of other explanations.

Dr. Savill, from his inquiry at Warrington on behalf of the Vaccination Commission, and elsewhere, believed that a sufficient belt of space around a hospital was very desirable, but solely for the purpose of efficient ventilation, not to avoid aerial convection, to which theory he could not subscribe. It was universally conceded that free fresh air was the best known natural germicide, and he failed to understand how it could become the vehicle for carrying contagion to such distances as had been alleged. There were also other grounds for disbelieving that it could take place. Cross-examined by Mr. Warrington, Q.C., on the plans of Whitemoor Common, he thought the site a good one. He admitted that infection could be taken within the limits of an ordinary room or ward by a person who simply breathed the patients' respiratory impurities, but not beyond this limit in presence of fresh air.

Dr. Orme Dudfield's evidence dwelt on the necessity of proper administration within the hospital in preference to a large area around it as the best means of preventing spread.

The other medical witnesses for the defence gave similar evidence.

Mr. Justice Kekewich, in the course of a long and elaborate judgment, first excluded from his consideration such points as the alleged greater suitability of other sites, and the accessibility of this one. The question was, "Is there here a real apprehension of real danger to the inhabitants or damage to their property or their trade?" If the existing cottage, and arrangements as now made, were used for small-pox patients the evidence went to show that there would be danger by reason of direct infection. In that sense, therefore, it constituted a "nuisance," and the plaintiffs were entitled to a verdict so far as the present arrangements were concerned. But the plaintiffs also sought to restrain the defendant Board from erecting a suitable small-pox hospital on this site. It had been shown in evidence that a properly built and administered hospital could be erected here, and the only question which remained was concerning the area of uninhabited space around, and whether small-pox could be contracted by persons frequenting and dwelling on the adjacent land. The real question, then, was, "Is aerial convection a theory sufficiently established to enable the Court judicially to say this constitutes a source of danger against which the defendants have to provide?" But his lordship had not been satisfied by the evidence before him that such a theory had been conclusively proved to exist, nor that the "particulate matter" referred to by one medical witness could be conveyed a mile, half a mile, or even a quarter of a mile. Under such circumstances it would be entirely wrong to grant an injunction against the defendants erecting this hospital, which would be an advantage to the public, because some learned men, whose opinions were entitled to great respect, came to the conclusion, though they could not prove it, that small-pox was the subject of aerial convection. The case came before him almost as a *res integra*, for his lordship had not found any reported case to assist him in coming to a conclusion.[1] But on the evidence he was of opinion that he should be going much too far in saying that there was any real apprehension of a real danger. The verdict would therefore be for the defendant board upon their undertaking (as they had consented to do) not to use the existing cottage and site for small-pox patients until a proper hospital had been erected; but, as each side had failed in part of the action, no order would be made as to costs.

[1] The case of Hill v. Metropolitan Asylums Board was finally concluded by arbitration.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A MEETING of the Comitia of the Royal College of Physicians was held on Friday, the 22nd inst., the President, Sir J. Russell Reynolds, Bart., being in the chair.

The President announced that he had nominated Dr. J. F. Payne as Harveian Orator for 1896. He also reported to the College that at a meeting held on the previous day at the University of London, Sir James Paget presiding, delegates of various bodies concerned in the question of the reconstruction of the University were selected to attend a deputation to the Duke of Devonshire on Nov. 28th. The delegates of the Royal College of Physicians were the President, the Registrar, Dr. Norman Moore, and Dr. Allchin.

The College seal was set to a deed declaring and accepting on the part of the College the Weber-Parkes prize trust.

A letter of thanks was received from the Cambridge Antiquarian Society for permission to photograph certain objects of interest possessed by the College.

A letter was read from the secretary of the Royal College of Surgeons reporting the proceedings of its Council.

A letter was read from Sir Arthur Watson resigning the office of standing counsel, which he had held since 1872. On the motion of the Registrar, seconded by the Senior Censor, Sir A. Watson's resignation was accepted, and a cordial vote of thanks passed to him for his valuable services.

On the motion of Dr. J. K. Fowler, seconded by Dr. Poore, permission was renewed to the Fellows' Club to dine in the College.

The report of the delegates of the two Royal Colleges on the proposed third and fourth examinations under the five years' scheme was received. The Registrar reviewed the various steps taken in the framing of the original scheme, and stated that the present revised plan was almost exactly the same as that which had been recommended in 1871 by the delegates of the College on the Committee of Management. The scheme, which would come into force in January, 1896, established the third examination (medicine, surgery, and midwifery) at the end of the fifth year, with certain extensions over the present examination; and permitted the examination in midwifery to be passed at any time after the completion of the fourth year of professional study, provided one year has elapsed since passing the anatomical and physiological examination. It also established an examination in pharmacology to be passed at any time after the completion of the fourth year of professional study, provided that the anatomical and physiological examination has been passed. Amongst other matters it recommended that the subject of elementary anatomy be eliminated from the first examination. Considerable discussion arose upon the desirability of instituting a separate examination in pharmacology, in which Dr. Curnow, Dr. Payne, Dr. Church, Dr. Fowler, Dr. S. West, Dr. I. Owen, Dr. Ewart, Dr. Poore, Dr. Cayley, Dr. Coupland, and Dr. Taylor took part. Eventually it was moved by Dr. Church, seconded by Dr. Curnow, and carried, that the report of the delegates be adopted, but that the Royal College of Surgeons be informed that this College would regard it as an improvement if the subject of pharmacology were included with the other subjects of the medicine examination, and not made a distinct examination by itself. Dr. Griffiths moved, and Dr. Playfair seconded, that the subject of midwifery and diseases of women be placed on the same footing as medicine and surgery—i.e., relegated to the end of the fifth year. The motion was negatived by sixteen votes to nine.

On the motion of Dr. Champneys, seconded by Dr. Playfair, a committee was appointed to prescribe the proper conduct of a practitioner when brought into relation with a case of acknowledged or suspected criminal abortion. The committee consists of the four censors, the mover and seconder, and Dr. Black.

A TEACHING UNIVERSITY FOR LONDON.

AT a meeting held at the University of London, on Thursday, the 21st inst., Sir James Paget, Bart., in the chair, and attended by delegates from institutions named in the report of the Royal Commission on the Gresham University, by members of that Commission and of the earlier Commission on a Teaching University for London, and by others interested in the establishment of a Teaching University, the following resolution was unanimously passed:—

"That the Government be requested to introduce, at an early date, a Bill, similar to Lord Playfair's London University Commission Bill, 1895, appointing a Statutory Commission to carry out the recommendations of Lord Cowper's Commission, but with an added clause giving [in accordance with precedent Acts of a similar tenor] to all institutions or persons directly affected by any Statute or Ordinance proposed by the Statutory Commission a right of appeal to the Privy Council for the

Digitized by Google

disallowance or alteration thereof, previous to such Ordinance being laid before Parliament for confirmation."

A second resolution was passed to the effect that a deputation in favour of this resolution should wait upon the Duke of Devonshire at the Privy Council Office.

This deputation, which waited upon the Duke of Devonshire on Thursday, Nov. 28th, was introduced by Lord Kelvin.

The following representatives of institutions explain the object of the deputation: Professor Rücker, for the Senate of the University of London; Dr. Allchin, for the Royal College of Physicians; Mr. Heath, for the Royal College of Surgeons; Sir George Young, for University College; Dr. Wace, for King's College; Dr. Frederick Taylor, for the Medical Schools; the Rev. Principal Whitehouse, for the Theological Colleges; Sir Henry Roscoe, for the Professorial University Association; Professor Silvanus P. Thompson, for the Annual Committee of Convocation; and Mr. James Anstie, for the Committee of Graduates.

In replying, the Duke of Devonshire said he would not commit either himself or the Government to any definite decision, but would lay the whole matter before his colleagues. At the same time he urged them by every possible means to inform those who opposed the scheme from misunderstanding of its true nature, in order that there might be as little opposition as possible should a Bill come before Parliament.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Enteric Fever at New Delaval, by Dr. Sweeting [1]—New Delaval lies in the Tynemouth rural district, about ten miles north-west of Newcastle-upon-Tyne, and it has a population of 1975 with 331 houses. The report refers to 129 cases of enteric fever in the six months August, 1894, to January, 1895, in addition to certain cases that were not notified and to a synchronous prevalence of diarrhœa. Dr. Sweeting discusses the outbreak at considerable length, and the reader is materially assisted by a lithographic plan of the place, in which the houses affected with the fever are specially marked in their relation to the local drainage system. He also describes the general sanitary circumstances of New Delaval. The place is provided with midden-privies having all the worst faults of this offensive system, and the water-supply is derived from a spring issuing from the sandstone at the foot of a declivity. Thence it is piped by ordinary field pipes to a collecting well, called a "tank," which further receives the overflow from an open dipping well or trough. Previously to Dr. Sweeting's visit the tank was open to contamination; indeed, the ground around it was early this year found to be the ordinary defecating place for tramps and others; the latter apparently preferring the open air to the stinking midden-privies. A drainage theory of causation had obtained local support, but after a careful analysis of all the circumstances involved Dr. Sweeting is unable to accept it as a definite cause. On the other hand, the localisation of the disease over other areas than New Delaval, but having the same water-supply, gave special force to the view that the water had served as a means of conveying the infection. The actual source of the prevalence at its onset was not a matter that admitted of demonstration; but, given its importation, the local conditions of unwholesomeness, including the risks of the excremental pollution of the water service, amply sufficed to explain its subsequent diffusion. And even importation would not be far to seek in an area which has long had much enteric fever. This report is well compiled and deserves careful reading by those who are interested in etiological investigations.

Diphtheria at Potterne, by Dr. S. MONCKTON COPEMAN.[2]—For some years antecedent to 1893 diphtheria had been practically unknown in the parish of Potterne, which lies in the Devizes rural district and has a population of nearly 1200. By the third week of July, 1893, the disease had led to 18 attacks; the schools seemed to be identified with its spread and they were closed, but the disease was maintained through August. It then abated, and had practically disappeared in December. Several attacks, however, occurred again in the period January—March, 1894, but there being comparative freedom from the disease, the schools were opened in April. Within ten days there were 3 fresh cases; and, some subsequent cases occurring, the school work was again suspended on June 1st. The disease, however, soon spread, and other cases occurred right up to a time when the reopening of the schools was once more permissible, on Aug. 20th. In fact, 143 cases of diphtheria were notified in Potterne in sixty-five households from July 18th, 1893, to Oct. 6th, 1894, and yet not a single case occurred among the large number of children of the better-class residents in the parish. The origin of the disease remains undetermined; indeed, Dr. Copeman found all trace of source lost amongst certain cases of so-called "sore-throat." As to its spread, a number of conditions commonly regarded as having to do with its diffusion are set aside; but it seems clear that at certain stages the aggregation in school of susceptible persons was concerned with it, and that, apart from this, personal infection came largely into play. The school was badly ventilated, one class-room was distinctly "fusty," and the flooring and foundations were not so constructed as to avoid damp and ground air getting into the building. These are conditions which, though they may not explain the onset of the disease, are such as would certainly tend to its diffusion amongst the school attendants, if not do more by producing a condition of unhealthiness in the fauces such as would render the individual particularly susceptible to receive the infection. Dr. Copeman reports that these conditions have now been remedied in accordance with his advice, and we may hope that no further prevalence of the same sort may arise.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Lancashire County Sanitary District.—Mr. Edward Sergeant estimates the population of the administrative county of Lancashire for 1894 as 1,870,141. The general death-rate of the county for the year in question was but 16·16 per 1000—i.e., 16·42 in the urban and 14·87 in the rural districts. Mr. Sergeant reports that during 1894 medical officers of health have been more careful to take into account the deaths of persons belonging to their districts but occurring in outside institutions. It appears, however, that a not inconsiderable number of the deaths in the county still remain unappropriated, and the writer of the report somewhat significantly remarks: "It may be observed that the tendency to put the best complexion on the statistics is more noticeable in residential districts and in certain districts desirous of acquiring reputations as health resorts." The infantile mortality for 1894 was a low one, being but 134 per 1000 registered births, as compared with a rate of 177 in 1893. In connexion with infantile mortality several of the district medical officers of health refer to the necessity for limiting the use of the feeding-bottle in the manufacturing towns. In the matter of small-pox an interesting instance of the influence of tramps on the spread of disease is given in the report before us, one tramp being instrumental during his wanderings in infecting directly or indirectly no less than twenty-six persons. During the year the Chadderton, Royton, and Crumpton joint hospital district was formed under the provisions of the Isolation Hospitals Act, 1893; but in connexion with the subject of isolation accommodation we regret to see that the Prescott urban sanitary district has requested its medical officer of health to refuse admission into the local fever hospital unless the guarantee of the payment of a guinea a week is forthcoming or the patient is provided with a magistrate's order. We shall not be surprised if the hospital in question goes down to posterity as one that did not fulfil its purpose. The supervision of dairies, cowsheds, and milkshops still seems in a backward condition in the county, although in some districts these places are conscientiously inspected. The smoke nuisance has been specially inquired into during 1894, and as a result of a recommendation on the part of a public health committee of the county council some attention seems to have been paid to the matter. It is, nevertheless, true that Section 91 of the Public Health Act, 1875, is not

very far from being a dead letter in the administrative county. Mr. Sergeant speaks highly of the energy displayed by the Lancashire Watershed Committees, and the effects of their labours will, he thinks, soon be apparent in an improved condition of the rivers.

St. Pancras Urban Sanitary District.—Dr. Sykes comprises in his annual report for 1894 the very interesting paper which he presented in May of that year to the St. Pancras Public Health Committee upon the causes of increased diphtheria mortality in London, and which we noticed at some length in a leading article in THE LANCET of July 14th, 1894. In that article we carried on Dr. Sykes' figures to the years 1892 and 1893, and we showed that the inferences which were apparently to be drawn from his report were not borne out by the figures which had been published since. In his present annual report Dr. Sykes has himself continued his observations so as to include the 1894 figures, and the whole paper now forms a highly valuable contribution to the literature of the subject. The St. Pancras Family Shelter was in use during the whole of 1894, and altogether 39 persons took advantage of it. In his report Dr. Sykes gives a summary of the isolation provision of the metropolis, and refers to the great inconvenience which has hitherto accrued from the absence of a fever ambulance station at Hampstead. The delay to the St. Pancras patients has been considerable owing to the fact that it has been necessary to send either to Fulham or Homerton to obtain an ambulance.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6311 births and 3863 deaths were registered during the week ending Nov. 23rd. The annual rate of mortality in these towns, which had been 22·1 and 19·1 per 1000 in the two preceding weeks, further declined last week to 19·0. In London the rate was 17·7 per 1000, while it averaged 20·0 in the thirty-two provincial towns. The lowest rates in these towns were 12·6 in Brighton, 13·1 in Norwich, 13·2 in Croydon, 14·9 in Bristol, and 15·7 in Preston; the highest rates were 24·7 in Birkenhead, 26·2 in Oldham, 27·2 in Liverpool, 27·3 in Salford, and 32·3 in Blackburn. The 3863 deaths included 548 which were referred to the principal zymotic diseases, against 606 and 522 in the two preceding weeks; of these, 208 resulted from measles, 111 from diphtheria, 69 from diarrhœa, 55 from "fever" (principally enteric), 54 from whooping-cough, 50 from scarlet fever, and 1 from small-pox. No fatal case of any of these diseases occurred last week in Plymouth; in the other towns they caused the lowest death-rates in Brighton, Bolton, Croydon, and Derby, and the highest rates in Oldham, Wolverhampton, Burnley, Salford, and Blackburn. The greatest mortality from measles occurred in Liverpool, Salford, Burnley, Oldham, Blackburn, and Wolverhampton; from scarlet fever in Birkenhead; from whooping-cough in Cardiff; from "fever" in Salford and Sunderland; and from diarrhœa in Blackburn. The 111 deaths from diphtheria included 69 in London, 8 in Birmingham, 6 in West Ham, 4 in Salford, and 3 each in Manchester, Birkenhead, Bristol, and Newcastle-upon-Tyne. One fatal case of small-pox was registered in West Ham, but not one in any other of the thirty-three large towns. There were 89 small-pox patients under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 23rd inst., against 106, 78, and 86 at the end of the three preceding weeks; 20 new cases were admitted during the week, against 29, 14, and 23 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2807, against 2841, 2847, and 2845 on the three preceding Saturdays; 296 new cases were admitted during the week, against 215, 349, and 298 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 447 and 340 in the two preceding weeks, further declined to 327 last week, and were 119 below the corrected average. The causes of 69, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Bradford, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Bristol, Leicester, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·4 and 18·5 per 1000 in the two preceding weeks, further declined to 18·1 during the week ending Nov. 23rd, and was 0·9 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·5 in Leith and 13·7 in Perth to 18·9 in Paisley and 23·3 in Aberdeen. The 521 deaths in these towns included 15 which were referred to diarrhœa, 12 to scarlet fever, 10 to whooping-cough, 8 to "fever," 3 to diphtheria, and not one either to measles or small-pox. In all, 48 deaths resulted from these principal zymotic diseases, against 77 and 52 in the two preceding weeks. These 48 deaths were equal to an annual rate of 1·7 per 1000, which was 1·0 below the mean rate last week from the same diseases in the thirty-three large English towns. The 15 fatal cases of diarrhœa exceeded by 4 the number in the preceding week and included 11 in Glasgow. The deaths from scarlet fever, which had declined from 11 to 9 in the three preceding weeks, rose again to 12 last week, of which 7 occurred in Glasgow and 3 in Aberdeen. The fatal cases of whooping-cough, which had been 21 and 18 in the two preceding weeks, further fell to 10 last week, and included 6 in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. The deaths referred to different forms of "fever," which had been 9 and 3 in the two preceding weeks, rose again to 8 last week, of which 5 occurred in Glasgow. The 3 fatal cases of diphtheria showed a further decline from the number recorded in recent weeks, and included 1 each in Edinburgh, Dundee, and Greenock. The deaths referred to diseases of the respiratory organs in these towns, which had been 173 and 134 in the two preceding weeks, further declined to 123 last week, and were 19 below the number in the corresponding week of last year. The causes of 28, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 31·5 to 23·1 per 1000, rose again to 23·9 during the week ending Nov. 23rd. During the past eight weeks of the current quarter the death-rate in the city has averaged 24·5 per 1000, the rate during the same period being 18·3 in London and 17·5 in Edinburgh. The 160 deaths registered in Dublin during the week under notice showed an increase of 5 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against numbers declining from 29 to 6 in the six preceding weeks; of these, 5 resulted from diarrhœa, 3 from "fever," 2 from scarlet fever, and not one either from small-pox, measles, diphtheria, or whooping-cough. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 3·0 in London and 1·0 in Edinburgh. The fatal cases of diarrhœa, which had been 2 in each of the two preceding weeks, increased to 5 last week. The deaths referred to different forms of "fever," which had been 4 and 2 in the two preceding weeks, were 3 last week. The 2 fatal cases of scarlet fever exceeded the number recorded in any recent week. The 160 deaths in Dublin last week included 34 of infants under one year of age, and 48 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded the numbers recorded in the preceding week. One inquest case and 3 deaths from violence were registered; and 49, or nearly a third, of the deaths occurred in public institutions. The causes of 10, or more than 6 per cent., of the deaths were not certified.

THE SERVICES.

MOVEMENTS OF MEDICAL STAFF.

IN addition to the names which we published last week the following officers complete the list of those proceeding with the expedition to Ashanti:—Surgeon-Lieutenant-Colonel Blennerhassett, Surgeon-Major Beatty, Surgeon-Captains Burke, G. Wilson, Corcoran, and Cummins, and Surgeon-Lieutenant Spencer. The following officers have arrived from India on relief:—Surgeon-Major Smythe and Surgeon-Captain Bullen. Surgeon-Major-General Hamilton

Digitized by Google

has arrived from the Cape and been appointed to the Western District. Surgeon-Major Truman has been posted to Dublin. Brigade-Surgeon-Lieutenant-Colonel Knox and Surgeon-Majors Maunsell, Maconachie, and Dixon have left India on completion of a tour of service. Surgeon-Colonel T. Maunsell will succeed Surgeon-Major-General Inkson as Principal Medical Officer at Malta.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Mathew D. O'Connell, M.D., to be Brigade-Surgeon-Lieutenant-Colonel, vice C. White, retired.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain F. E. Swinton is appointed Personal Assistant to the Principal Medical Officer, Bombay Command. Surgeon-Lieutenant MacDonald is appointed to the Officiating Medical Charge of the 14th Bombay Infantry. Brigade-Surgeon-Lieutenant-Colonel G. W. R. Hay has taken charge of the office of the Superintendent of Matheran. Surgeon-Lieutenants Gibbs and Rivers have been transferred from Bombay District to the Sind District.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Surgeons: J. Dowson to the *Basilisk*; W. G. Stott, M.B., to the *Victory* for the *Duke of Wellington*.

VOLUNTEER CORPS.

Artillery: 5th Lancashire: Thomas William Butcher, M.B., to be Surgeon-Lieutenant. 4th Durham (Western Division, Royal Artillery): Harry Harte Gourley, M.B., to be Surgeon-Lieutenant. *Royal Engineers:* 1st Middlesex: Surgeon-Lieutenant-Colonel M. Baines, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement. *Rifle:* 5th (Irish) Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Captain D. F. Flinn to be Surgeon-Major. 2nd Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Lieutenant-Colonel J. E. Foster resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 3rd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant J. Mason to be Surgeon-Captain.

THE REORGANISATION OF THE WAR OFFICE.

The new Order in Council for the reorganisation of the War Office has been published, and it proves to be very much what was anticipated. The principles laid down in the report of the Hartington Commission have in the main been followed, but certain modifications have been beneficially made and introduced. The recommendation for the appointment of a chief of the staff has, for instance, been set aside. The future administrative machinery and the details of the new system are plainly set forth in the Order and its accompanying explanatory memorandum. A greater division, and consequently a corresponding curtailment, of labour has been effected, but the commander-in-chief exercises a general power and authority over the whole organisation. With a military board containing Sir Redvers Buller and Sir Evelyn Wood, in conjunction with the other members, under the presidency of Lord Wolseley, there should be no practical difficulty in working the new system. It will be seen that the new order of things is to some extent a compromise, but we do not on that account see why it should not work efficiently and well; the commander-in-chief is, and always must be, something more than *primus inter pares*. The quartermaster-general deals, as heretofore, with all supplies, transport, the movement of troops and their equipment, and with all sanitary questions relating to the army. Among the military departments which report to the commander-in-chief, the adjutant-general or the quartermaster-general is the director-general of the Army Medical Department who is charged with the administration of the medical establishments of the army, the Medical Staff Corps, the preparation of medical, sanitary, and statistical returns, and the supply of medical stores to the army. This states, in other words, that the functions of a director-general are general medical direction, just as those, to parody another well-known definition, of an archdeacon are archidiaconal.

THE FRENCH IN MADAGASCAR.

The latest reports of the French in Madagascar are more satisfactory, and things appear to be quietly "settling down" in that country. According to all accounts nothing could have been better or more humane and orderly than the conduct and discipline of the French force after the capture of Antananarivo. The sickness and suffering among the French soldiers have been very great in this expedition, and they have borne these with great fortitude. We can only hope that they are now at an end, and that when the new Treaty between Madagascar and France has been finally settled affairs in Madagascar may be greatly improved. The great defects and mistakes of the campaign seem to have been the youthfulness and immaturity of so many of the troops sent out to Madagascar, the deficiency of supplies and transport, the employment of young soldiers in road-making in a highly malarious and hot climate, and the relative absence of hygiene. The sickness and loss of life entailed by the road-making would most probably have been altogether avoided if the French had taken care to have organised a large force of native bearers and speedily pushed on to higher and healthier localities and to the capture of the capital. It is pitiable to read the descriptions of the physical weakness and anæmic condition of so many of the French soldiers on their arrival at Antananarivo, and it says much for their discipline and powers of endurance that they persevered in the way they did in prosecuting the campaign to a successful issue.

SANITARY COMMISSIONERSHIPS IN INDIA.

We notice in the Anglo-Indian papers that it is proposed by the Indian Government to abolish a number of the sanitary commissionerships in order to raise funds for the establishment of a bacteriological institute at Agra. Although we fully recognise the importance of bacteriological researches, and have advocated the establishment of bacteriological laboratories in India, we regard it as a false and retrograde step to decrease the numbers of the present sanitary staff in that country. There is a quantity of detailed sanitary work of a practical kind to be carried on in India, the necessity of which has, first of all, to be urged upon the attention of the authorities and then the work itself has to be supervised and inspected, if the hygienic conditions of India are to be improved. We do not see how this is to be done without the aid of a sanitary staff, and that which exists at the present time is not upon such a liberal scale as to admit of its being curtailed. By all means establish bacteriological institutes in India, but see that the practical sanitary work of the country, such as that which devolves upon the health officers and the Medical Department of the Local Government Board of this country, is carried out at the same time. Bacteriological researches and other scientific work are but necessary means to an end, and the two have to go on together if practical results are to be reaped.

THE SUCCESSORS TO SIR THOMAS CRAWFORD, SIR THOMAS LONGMORE, AND SURGEON-GENERAL IRVINE.

The *London Gazette* of Nov. 26th announces the following appointments: — Surgeon-Major and Honorary Deputy-Inspector-General Richard Domenichetti, M.D., retired, late Army Medical Department, to be Honorary Physician to the Queen, vice Surgeon-General J. Irvine, M.D., retired pay late Medical Staff, deceased (dated Nov. 27th, 1895). Surgeon-Major-General Charles Dodgson Madden, retired pay late Medical Staff, to be Honorary Surgeon to the Queen, vice Director-General Sir T. Crawford, M.D., F.R.C.S.I., K.C.B., retired pay late Medical Staff, deceased (dated Nov. 27th, 1895). Surgeon-General Herbert Taylor Reade, V.C., C.B., retired pay late Medical Staff, to be Honorary Surgeon to the Queen, vice Surgeon-General Sir Thomas Longmore, Knt., F.R.C.S. Eng., C.B., retired late Army Medical Department, deceased (dated Nov. 27th, 1895).

DEATHS IN THE SERVICES.

Surgeon-Major Dobson, F.R.S., of the Army Medical Service, at West Malling, on the 26th inst., after a long illness. The deceased officer was born in 1848, and was educated at Trinity College, Dublin, where he graduated in 1866, and entered the Army Medical Department in 1868, from which he retired after twenty years' service. He was a man of very considerable scientific attainments and the author of many works and original researches in zoology and comparative anatomy. Surgeon-Major Dobson was for a long time at Netley, where he did good work in connexion with the museum. He retired from the service many years ago in consequence of ill-health.

Digitized by Google

The *Army and Navy Gazette* prints the following records of Surgeon-General J. O'Nial, C.B., retired pay, and Surgeon-Major-General J. Warren, who have been awarded good pension rewards. Surgeon-General O'Nial has taken part in five campaigns—the Kaffir War, 1852–53; the North-West Frontier of India campaign, 1863; the Afghan War, 1880; the Soudan expedition, 1884–85; and the Soudan, 1885–86. For Afghanistan and the Nile expedition he was mentioned in despatches, and for the latter promoted Surgeon-General. Surgeon-Major-General Warren took part in the Afghan War, 1878–80; the Egyptian expedition, 1882; and the Soudan expedition, 1885, and for the last-mentioned was mentioned in despatches.

A committee consisting of Brigade-Surgeon-Lieutenant-Colonel King, Superintendent of the Royal Botanical Garden, Calcutta (President); Surgeon-Lieutenant-Colonel McConnell, Professor of Materia Medica and Clinical Medicine, Medical College, Calcutta; Dr. George Watt, Economic Reporter to the Government of India; and Rai Bahadur Kanny Lall Dey, has been appointed to consider the whole question of Indian drugs.

Surgeon-Major-General Cleghorn, surgeon-general with the Government of India, has left Simla on tour, proceeding to Agra and Bombay.

Correspondence.

"Audi alteram partem."

THE EXAMINATIONS AT THE LONDON COLLEGES.

To the Editors of THE LANCET.

SIRS,—When it was decided that the medical student's course of study should extend over five years, hopes were entertained in many quarters that, whatever else might happen, the two London Colleges would at last take care to bring the clinical part of their examinations up to a high standard of efficiency. It must be with feelings of surprise and disappointment that those who cherished this hope now find how trivial, when compared with the high importance of the subject, is the place given to the clinical examinations in the most recent proposals of the delegates, to whom the Colleges have entrusted the consideration of the arrangements of the examinations. Here is the proposal of the delegates in their own words: "That the time of the clinical part of the examination in each subject (medicine and surgery) be extended to thirty minutes." *Extended* to thirty minutes! What must this examination have been when it did not cover even thirty minutes! Will anyone have the courage to say, that within the space of thirty minutes a medical student can be examined clinically in such a way as to give him a fair chance of showing what he knows of clinical medicine or of clinical surgery? To make such an examination what it ought to be, the student should be invited to enter the ward of a hospital, and there, with abundance of time at his disposal, should be asked to give the examiners an insight into what he knows of the conditions of disease shown in the cases in the ward. Were some such system of clinical examination as is here indicated adopted by the two Colleges and thoroughly carried out by them, it would soon be admitted on all hands that men who went into practice with the qualifications of the Colleges were as efficiently equipped for the most important of the daily duties of the medical practitioner as newly qualified men could be.

In these days, when examinations are believed to play so important a part in barring the entrance to professional life against incompetent men, a very important and significant discovery has been made. I have spoken to several examiners of large experience with a view to ascertaining whether or not they are agreed in accepting it as a fact that there are men who have a special aptitude for passing examinations, and who, nevertheless, show less than ordinary ability in efficiently dealing with the affairs that make up the work of the practitioner of medicine. This is the discovery which, I say, has been made, or at all events emphasised, by the outcome of examinations; and I do not remember that any one of the examiners with whom I discussed the matter denied the truth of this discovery, or contradicted the assertion that no examination scheme has yet been devised which can be trusted to keep incompetent men out of the medical profession. I do not say that the system of clinical examination indicated in this letter would keep incompetent men out of our profession, but I do say it would be vastly more efficient for this purpose than the mass of paper work which now forms the bulk of the final examination for the qualifications of the Colleges. Not the least of the advantages of a clinical examination, properly conducted on the lines mentioned above, is that it would be impossible to "cram" students for such an examination.

Objection may be taken to the scheme here suggested on three grounds. In the first place, it may be said that sufficient time could not be given by the examiners for the thorough carrying out of such a scheme. A second objection might be, that the examiners' fees would amount to an impracticably large sum. And, lastly, it might be asked, Where is a sufficient number of examiners to be found? There are to be found among the Fellows of the two Colleges plenty of men perfectly well qualified, and able and willing to give the time necessary for the efficient carrying out of such a clinical examination as is here outlined; and I should be greatly surprised if the question of fees, when it came to be looked at closely, were to prove an insuperable obstacle.

I know there are men of the highest standing in the profession of medicine who are entirely at one with me in the views I have here expressed, and I venture to hope that they and others will not allow this matter to drop until clinical examinations are made, as I contend they ought to be, the most important and the most thorough of the tests to which medical students have to submit themselves.

I am, Sirs, yours truly,

Nov. 26th, 1895. G. A. HEBON.

"THE ADMISSION OF WOMEN TO THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—Many of the arguments brought against the admission of women to the London Colleges shew very plainly that those who advance them have no acquaintance whatever with medical women and no knowledge of the extent to which the movement in their favour has progressed during the last few years. Mr. Truman tells us that the profession owes a debt of gratitude to the London Colleges for their verdict; it is difficult to see why. If their decision had involved the entire exclusion of women from the profession his position would be comprehensible, but in all probability not a single woman who wishes to will be debarred from entering. Those who do not take the L.S.A. or the M.B. Lond. will merely go to the Scotch Colleges instead of the London ones, or very possibly to the Scotch Universities (let London diplomates who dislike the competition of Scotch M.D.'s note the fact), and probably the only people who can really congratulate themselves are some of our Northern friends who see more grist brought to their mills by the action of their less astute London brethren. But, say the opponents of the women, by all means let them go anywhere else than to our Colleges. Meanwhile, however, we shall have to reckon with public opinion, which year by year is being more emphatically expressed in favour of medical woman. Note the action of our representative bodies: the Government gives a woman a medical appointment at the Post Office, the London County Council appoints one as assistant medical officer at the Claybury Asylum, the Metropolitan Asylums Board puts one on the staff of the North-Western Fever Hospital, and the governing bodies of hospitals and infirmaries all over the country are constantly adding to the number of women who fill responsible hospital posts; in fact, if some of your correspondents were to see a complete list of appointments obtained by medical women during the last few years it is difficult to say whether astonishment or jealousy would be their predominant emotion. In addition, the women have founded and fully officered a hospital of their own, where they successfully deal with the gravest cases both medical and surgical. And yet—let us hope in ignorance of all this—we are told that women faint at the sight of blood and are unfit both physically and morally to practise medicine. Those who are brought into contact with them in teaching and examining are surely best qualified to judge on these points, and I believe all who have had such opportunities favour their claims. Even an afternoon spent at the *Royal*

Digitized by Google

Free Hospital or at the New Hospital for Women in Euston-road would dispel many fallacies in the minds of those who argue on theoretical premises only. Of course all must agree with Mr. Brindley James's rhapsody on women and home, although he is above troubling himself as to whether all can find homes; but a personal knowledge of medical women would probably teach him that many of them would grace the profession even more than the domestic circle. We must beware of arguing merely from averages and of thinking that because most women are unsuited for medical work that therefore all are. The same fallacy has been exposed in regard to mathematics. A few years ago I was no friend to the movement, but an acquaintance with the women students, their earnestness, their power of work, and, above all, their practical ability, have forced me to believe in their claims.

Mr. Morton, glancing with prophetic insight into the future, draws an appalling sketch of women teaching men. A few years ago an equally terrible picture would have been drawn of men teaching women, and yet for years many of us have done so, we hope without serious moral injury, and certainly without social or professional ostracism, and I fail to see any material difference between the two if a woman should happen to be a more competent teacher than a man. Let the opponents of the women rejoice over their pyrrhic victory while they may. But would not the party of reform at the Royal College of Surgeons be well advised to make friends with them; they might find them valuable and congenial auxiliaries in their crusade against the Council? They must know themselves—if they will only face the facts — that a cause which has made such tremendous strides during the last few years in the face of prejudice and opposition; a cause which has already obtained the admission of over 200 women into the profession and the establishment of a fully-equipped medical school in London with about 150 students with a large, well-arranged hospital for their training; a cause which is approved by the Council of the Royal College of Surgeons and was nearly carried at the Royal College of Physicians, despite a strong whip-up on the other side, is not likely to be long retarded by the conscientious prejudices of an expiring generation or by the efforts of those whose very arguments conclusively prove that they have no adequate knowledge of the subject.

I am, Sirs, yours faithfully,

Cavendish-place, W., Nov. 26th, 1895. J. WALTER CARR.

INFANTRY SWORD EXERCISE AND THE RECENT HANDBOOK FROM THE WAR OFFICE.

To the Editors of THE LANCET.

SIRS,—The letter from Dr. Chepmell and Dr. Savage, which appeared in your issue of July 27th, 1895, has excited a good deal of comment, and it is evident that the Italian system of sword exercise, now officially introduced, is not wanting in defenders. It may be well, therefore, to urge again, and with greater precision, the objections to the system, based on anatomical and physiological grounds. The chief of these are that the muscles mainly concerned in bringing about the offensive and defensive movements are unduly exerted, and made to act at an unnecessary mechanical disadvantage; rapidity and delicacy, and, in a great degree, range of movement, are sacrificed to an endeavour to obtain increased power in certain directions. If the position of "on guard" is considered it will be seen that some of these statements are at once justified. Here the feet are more widely separated than in the French position. The weight of the body, which is maintained upright, tending to act directly downwards, more exertion is obviously required to keep the knees properly bent than when the feet are brought nearer together, as in the French attitude of "on guard." The extensors of the legs on the thigh are concerned in preserving the prescribed Italian attitude, aided by the muscles which pass from the pelvis to the upper part of the thigh, principally the gluteals. The French attitude selects a position adapted to give the widest possible range of movement while departing as little as possible from the natural equilibrium of the body in the upright position. The "advance" and "retire," it is evident on anatomical grounds, can be made more rapidly in the French and with less expenditure of energy than in the Italian attitude; so, too, can recovery to the first position with the heels aligned, or the extension forward as in the lunge. Place two men of equal physique side by side, one in the Italian and the other in the French "on guard" position, and it will be found that fatigue ensues earlier in the former. The differences in the rapidity of movement between the two are, no doubt, extremely slight, but in sword play very minute fractions of a second have to be taken into account.

Next, as to the position of the hands and arms in the Italian "sword in line" or "on guard" positions. Here the arm is extended to a right angle with the vertical line of the trunk, so that the point of the sword, the hand and the shoulders are all in the same straight line. In this attitude of the arm the deltoid is exerting itself to the utmost. Any further raising of the arm would be accomplished mainly by the trapezius acting as the continuation of the deltoid. The triceps is acting to the utmost, the forearm being fully extended. The pronators are again acting to the utmost, for the hand is fully pronated. No further movement of pronation or extension of the forearm is, therefore, possible, and any advantage in sword play to be gained by these movements is therefore thrown away at the outset. Rapidity of movement is also sacrificed. The greatest possible speed and delicacy of movement is obtained when two such opposing muscles, or groups of muscles, are both acting and nearly balance each other. Thus with the hand completely pronated the initial act of supination must be slow. A fully-stretched muscle is not able to act quickly or advantageously. When the hand is midway between pronation and supination not only is a greater range of movement in either direction secured, but the greatest initial rapidity of action is rendered possible. The same applies to the extreme extension of the arm. Before the biceps and brachialis anticus can act with the best mechanical efficiency as flexors there must be relaxation of the triceps and slight flexion of the arm. That the deltoid is acting at the greatest possible mechanical disadvantage is obvious enough. Again, the French position of "on guard" fully recognises all these points, and the most restful possible position is coupled with infinite possibilities in the way of rapid movement. Again, let two men stand side by side, one in the Italian and one in the French attitude, and the arm of the former will tire much more rapidly than the latter, with the effect that the point of his sword will either drop or be raised.

Next as to the "lunge." The essential difference between the Italian and the French systems is that the body is thrown forward out of the vertical in the former and is maintained upright in the latter. There can be no question that greater power of thrust is obtained by the Italian lunge. Speaking, however, from the medical point of view, it appears to be a matter of little consequence whether a sword thrust goes many inches through the body or only a few. The anatomical disadvantages, however, of the Italian lunge are chiefly shown by the difficulty of recovery. In the *Broad Arrow* of Oct. 5th, 1895, a letter appeared over the signature of "On Guard" defending the Italian system, but employing arguments with which no anatomist could for a moment agree. In condemnation of the French lunge, as compared with the Italian, the writer states that there are two forward movements, that of the foot and that of the body; in the Italian system only one, that of the foot. Surely, the writer forgets the extension of the arm that takes place in the French lunge. With regard to the recovery, "On Guard" urges that the recovery must be quicker in the Italian system, for there is a double movement in recovering, "the direct backward swing of the body assisting enormously the muscles of the leg in executing the movement, not only by relieving the leg (the left) of some of its work, but also by increasing the rapidity of the movement." This view appears to be based on an anatomical misconception. In recovery from the Italian lunge, the centre of gravity being thrown far forward, the trunk has first of all to be straightened on the legs—that is, brought to a more or less vertical position. This has to be effected by the gluteal muscles, which, again, owing to the attitude, act at great mechanical disadvantage, and therefore act only slowly. The "backward swing" of the body, indeed, so far from assisting the rapidity of recovery, must inevitably retard it. Once the body has begun to swing back it may facilitate recovery to "on guard," but the initial movement, regarded from the purely mechanical point of view, must be slow and involve very powerful contraction of a single muscle in order to take place at all. Any attempt to recover merely by bending the left leg in the Italian lunge would cause the

Digitized by Google

lunger to fall forward. The French system fully recognises that the most rapid possible action and the greatest delicacy of movement is insured when opposing groups of muscles are simultaneously in action and the part on which they act, hand, arm, trunk, or leg, is midway between the positions that can be brought about by their extreme contraction. Further—and this seems a point of the greatest importance—this mid-position is one of comparative rest. The same considerations, though in a minor degree, apply also to the exaggerated "feather-edge" attitude prescribed in the Italian system. If in sword exercise rapidity and delicacy of movement, combined with good balance and adequate power of cut or thrust, are desirable, it is to be regretted that a system based on sound scientific principles should be replaced by one that possesses no such advantages.

I am, Sirs, yours faithfully,

Nov. 27th, 1895. C. T. DENT.

"CONSIDERATIONS IN RESPECT TO 'RETURN' CASES OF SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—I have read with much interest Mr. T. W. Thompson's very able paper in THE LANCET of Nov. 23rd on so-called "return" cases of scarlet fever. In all probability it will have the effect of drawing the attention of our metropolitan medical officers of health to the subject, and as the result we shall have all cases of such nature carefully noted and reported. During the time I was assistant medical officer at the Stockwell Fever Asylum—a period extending over five years—I had an opportunity of observing these so-called "return" cases, and came to the conclusion that with every care on the part of the fever hospital and sanitary authorities such cases would from time to time appear. With regard to the very important question—What is the explanation of these "return" cases?—when we consider the tenacity of the poison, the existence at times of recurrent desquamation, and that the patient may come from the fever hospital ward to his own home, it is hardly surprising we should have some "return" cases. I agree with Mr. Thompson that the throat is in all probability a factor in the propagation of the disease; often the chief stress of the malady is located there, and I think the importance of the spray and antiseptic gargles is sometimes overlooked. With reference to the desquamating cuticle being a powerful agent in its diffusion, Dr. Priestley's cases would not appear to support this view. The recurrent desquamation may be counteracted by the daily warm antiseptic bath, so often neglected by the parents on the return home of the patient. I incline to the opinion that some "return" cases may owe their origin not only to articles of clothing or otherwise escaping the action of the home disinfection, but also in some instances to the chemical agent employed, the action of chlorine appearing to be of a more reliable nature than sulphur. The desirability of keeping a child fresh from a fever hospital apart from healthy children, either by residence at a convalescent home or separation at its own home when it can be carried out, would be a wise precaution. The school influence also must not be lost sight of.

I am, Sirs, yours truly,

St. Leonards, Nov. 25th, 1895. SAMUEL LEE, M.D. St. And.

SAINT PATRICK.

To the Editors of THE LANCET.

SIRS,—In the review of the "Dictionary of National Biography" in THE LANCET of last week, it is stated that "Patrick, the famous patron saint of Ireland, was born in Scotland in the year 373, his father being a magistrate in Dumbarton, which was at that time a Roman fortress held by a Roman garrison." I should like, with your permission, to say that many Welshmen affirm that the saint was born in Wales, but most Irishmen believe that the place of Patrick's nativity was neither in Scotland nor in Wales, but in Armoric Gaul. This is the opinion of the learned Lanigan and of other Celtic or Irish historians of authority, who narrate that Patrick was born at Bononia, now Boulogne, part of the territory of ancient Armorica. Patrick's parents were respectable Roman citizens of Gaul. His father's name was Calphurnius, and his mother (Conchessa) was nearly related to St. Martin, the celebrated Bishop of Tours. According to Usher, Ware, Colgan, and other authorities, Patrick was born either in the year 372 or 373, and died on March 17th, 493, in the 120th year of his age. Lanigan, however, places his death in the year 465.

In the great and successful introduction of Christianity into Ireland two characters stand out prominently in the fifth century, namely, St. Patrick and Niall, the monarch of Ireland. It is a circumstance which so intimately connects Niall with Patrick that it is that it was Niall who took Patrick into Ireland. Niall was a famous warrior and made numerous military expeditions into neighbouring countries. In one of these expeditions into Gaul he made many captives, among whom was a youth who ultimately became the celebrated St. Patrick. The young man was sold as a slave to a chief named Milcho who possessed a district in that part of Dalaradia now the southern part of the county of Antrim, where he tended the flocks of his master beside Slieve Mis mountain. Patrick after a captivity of seven years, effected his escape and returned to his family in Gaul. Subsequently to this he spent several years in the monastery of St. Martin's at Tours also under St. German at Auxerre, and became eminent for his great piety. In the year 432 Patrick was consecrated bishop and appointed to be the successor to Palladius on the Irish mission. Palladius, it appears, was not quite a year in Ireland, having been compelled to quit the country in 431, the year of his arrival.

Patrick landed in Ireland in the year 432, and on Easter Sunday in the following year he preached the Gospel before the monarch Laoghaire, son of Niall, and a large assembly of chiefs, Druids, and people at the royal residence of Tara, and on Easter Monday he also preached before many distinguished chiefs at Tailten, another royal residence. From Tara Patrick journeyed from place to place in the execution of his mission, which extended over many years. He converted to the Christian faith nearly the whole of the people of Ireland, consecrated more than 300 bishops, with a great number of presbyters, founded many hundred churches, and having served the Christian Church—of which he was a shining light—well and faithfully he died full of days at Saul, near Downpatrick. St. Patrick was a man of small stature, but of immense energy and activity of mind and body. In all his intercourse with the Irish people he was affable, agreeable and polite, and to the Irish princes he invariably paid the greatest deference and respect, on account of their learning, their many virtues, and their manly and lofty bearing. St. Patrick gave a stimulus to the more general study of the Latin language in Ireland, but the educated Irish had a good knowledge of several languages as well as their own written language centuries before the time of St. Patrick. Indeed few nations made so much use and such good use of written language as the ancient Irish. Although St. Patrick is generally looked upon as the great Apostle of the Irish people, nevertheless the Gospel was preached in Ireland long before the time of Palladius or of St. Patrick. The old Irish annalists record three remarkable persons who became converts to Christianity before the missions of Palladius and Patrick—namely, Concovar MacNeasa, the king of Ulster in the first century; Moran, the famous judge or chief Brehon of Ireland, in the beginning of the second century; and the renowned Cormac, monarch of Ireland, who reigned in the middle of the third century.

I am, Sirs, yours truly,

WILLIAM O'NEILL, M.D., M.R.C.P. Lond.

Lincoln, Nov. 25th, 1895.

"A CASE OF DOUBLE PHLEGMASIA ALBA DOLENS IN A YOUNG VIRGIN."

To the Editors of THE LANCET.

SIRS,—I have just seen a recent note in THE LANCET of Oct. 5th from Dr. Herman on an interesting case of white swelling of both legs in a young anæmic girl, the anæmia being the only apparent accompaniment and cause of the phlegmasia. In 1891 I came in charge of a case which was almost literally identical in every clinical detail with that described by Dr. Herman, the only material difference being that the disease was confined to the right leg, though I remember now that I often felt doubtful whether the oedema found in the left ankle was not something more than that usual in severe anæmia, but then double phlegmasia alba in an unmarried girl aged sixteen seemed quite

too unlikely; the albumin, too, in the urine was so small in quantity and variable that throughout the case one as often as not failed to detect any presence of it, and when demonstrable it was never more than a decided trace. There was intense anæmia, with all the usual accompaniments, as the first condition, the white swelling appearing when the anæmia was well established, and at first it was regarded by the patient as an aggravation of the œdema of the ankle to which she had become accustomed, but it rapidly assumed all the appearances of an ordinary bad white swelling of the leg, the thigh up to the groin being the principal seat of complaint, and the pain being very severe.

Both the anæmia and the phlegmasia yielded in quite the ordinary way to treatment, but the cure occupied three months, including some six weeks in bed with light bandaging. During the ensuing eighteen months she had three relapses of diminishing intensity, anæmia first showing itself and the phlegmasia regularly developing in the course of a few weeks. At first she postponed treatment until the leg compelled her to lie up; but taught by a fourfold experience, she consented on the fifth occasion to treat her anæmia on its first appearance and more thoroughly, with the result that she has had no recurrence since. I was greatly interested and puzzled by the case at the time, and made notes for offering to THE LANCET, with the usual result and the usual self-excuse that it was sure to turn out the commonest of complaints described in dozens of "Transactions" and familiar to every other of your contributors. Now Dr. Herman's article has encouraged a hope that the condition may be sufficiently unrecognised to make the record of any case of interest or even useful.

I am, Sirs, yours truly,

CAMERON KIDD.

Bromsgrove, Worcestershire, Nov. 21st, 1895.

THE DIAGNOSIS OF TONSILLITIS.

To the Editors of THE LANCET.

SIRS,—I wish to inform you that we have had cases in the parish of Fulham very like diphtheria in its early stage, but most distinctly different in most important respects, for the symptoms pass off in less than a week, generally in from two to three days. It is a kind of tonsillitis arising perhaps from some condition of the air or from the sewer openings in the streets. We have reasons for knowing that, although the Klebs-Löffler microbe may be present, this disease is not diphtheria. The trouble and expense which may arise if mistakes are made by practitioners in these cases leads me to make objection to the course Mr. Wynter Blyth has taken.

I am, Sirs, yours truly,

Nov. 27th, 1895. ROBERT LEE.

THE NEED FOR MEDICAL MISSIONARIES.

To the Editors of THE LANCET.

SIRS,—Saturday (St. Andrews Day) is the day set apart for special intercession for missions. May I, as Provost of the Guild of St. Luke, draw attention to the demand that exists for medical missionaries. Of these about sixty are employed by the Church of England Missionary Societies, a third of whom are our associates. Several colonial bishops, members of the Guild, are urgently calling for helpers; the Bishop of Bloemfontein, himself a Fellow of the Royal College of Physicians, is now needing a medical missionary, so is the Archdeacon of Mashonaland, the Universities Mission in Central Africa, and the Chota Nagpur Mission in India. The salaries offered vary from £100 to £300 a year. The stations in which they are needed are not always unhealthy, although the demand is naturally greatest where disease is most rife. The call "to heal the sick" is as incumbent upon us as to "preach the Gospel" throughout the world, and we may fain hope that volunteers will come forward for this work. Men possessing knowledge of medical sanitation and tropical hygiene are specially needed. If our missionary societies could secure the services of one imbued with the spirit and the knowledge of Edmund Parkes, who would see that the mission stations were freed from every removable source of danger, who would select sites for new stations and arrange hospital accommodation for sick natives and convalescent missionaries, many valuable lives unnecessarily sacrificed would be preserved. The Archbishop of Canterbury has promised to preach for the Guild next year. Every loyal Churchman in the profession should be stirred to do what he can to promote our cause.

I am, Sirs, yours truly,

E. SYMES THOMPSON, M.D., F.R.C.P. Lond.,
Provost of the Guild of St. Luke.

Cavendish-square, W., Nov. 28th, 1895.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—I should be glad to be allowed to correct two slight errors in the report of some remarks of mine at the Leeds and West Riding Medical Society on Nov. 1st.—1. The blood from a patient with typhoid fever showed (not absence of, but) diminution in the number of leucocytes, a condition alleged to distinguish this from the other specific fevers. 2. I have looked in vain for four years—i.e., since hearing Dr. Lancaster's paper at the Clinical Society—for any distinctive uræmic rash; and I related a case in which universal pemphigus did not follow, but immediately preceded, nephritis, the latter disease appearing after recovery from the pemphigus and being attributed by the patient to chill consequent upon the removal of lint, ointment and bandages from the body generally. With the nephritis she had endocarditis and capillary bronchitis, but recovered in three or four weeks. The cure of the pemphigus, after some weeks' duration, was very rapid, as often happens; it followed saturation of the blood with carbolic acid applied in a lotion to ulcers on the legs. A recent, but less severe and earlier, case has also recovered with equal rapidity (two or three days) under the same treatment; but I have seen a sudden recovery when no carbolic acid has been (known to be) used.

I am, Sirs, yours faithfully,

Leeds. T. CHURTON, M.D.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Breeching Straps for Horses.

A CASE of some interest to medical men who drive daily rounds was lately discussed at the coroner's court. A coachman while driving in one of the principal streets was thrown from his box and killed on the spot. The horse had shied, got beyond the driver's control, and owing to collision of the brougham with a coal cart the accident happened. The coroner at the inquest laid great stress upon the horse being driven without a breeching strap. It was stated that there was a good break upon the brougham, and that breeching straps were seldom used either here or in London when carriages were driven. The danger was pointed out by the coroner in spite of the assertion of witnesses that the custom of doing without one prevailed, and a verdict of "Accidental death" was returned.

Level Crossing Accidents.

Two accidents of a preventable kind have lately occurred, in each of which a valuable life was lost, on a level railway crossing. In one at Water Orton the place is described as a death-trap. A young girl aged nineteen was run down by an express and killed instantly. The night was windy and a storm raging, but no extra provision for safety was made by the railway authorities. A previous death on the same spot occurred some years ago. In the second instance the body of a boy aged fifteen was found cut to pieces. Some precaution and protection necessary in such dangerous places; no doubt, where possible, level crossings should be done away with entirely, even though the right of way may present some difficulties, but in all cases it should be made apparent on the spot that great risk is taken by choosing a short cut.

Ambulance Competition.

The second annual competition for the silver challenge shield in connexion with the Birmingham corps of the St. John Ambulance Brigade took place at the Athletic Institute on the 18th inst. before a large assembly. It was stated that there were now 1157 members in the Ambulance Brigade, and that during the year ending June 30th 1457 cases occurred in which these members rendered valuable first aid. As the competition proceeded the skill and aptitude of the members evoked much applause. The tasks to which the competitors were submitted were an oral

Digitized by Google

examination and practical demonstrations, embracing stretcher-carrying, application of splints and bandages, arrest of hæmorrhage, and other departments of ambulance work. The results were—City Police, 334 marks; Great Western Railway, 310; and Midland Railway, 301. It was a very interesting exhibition, being thoroughly appreciated.

Adulteration.

The alleged sale of cassia as cinnamon was lately the cause of a prosecution at Hanley; the article was bought in Birmingham. The case was adjourned at first for two weeks to allow of an independent analysis. It was now stated that this was so expensive an undertaking that it could not be carried out efficiently. The defendant was fined 20*s.* and costs, £7 1*s.* in all. The moral is that an objection to the prosecution to be effective must be complete in all its details if it is to carry success or refutation.

Vegetarians in Conference.

At a recent conference held in this city a speaker said that in dealing with cancer vegetarianism was an important factor in treatment and cure. Another said that cancer was unknown among the natives in the presidency of Bombay. No doubt too much meat is eaten by the majority of our population, but two blacks do not make a white, nor does the use of meat carry its condemnation by being abused by indiscreet people ignorant of the elementary details of nature's laws.

Nov. 25th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Lord Derby and the Royal Southern Hospital.

LORD DERBY, in his capacity of Lord Mayor, followed the example of his predecessors in the civic chair during many years past and attended divine service at St. Michael's Church on Sunday last, when a sermon was preached and collection made on behalf of the Royal Southern Hospital. The collection amounted to £137, a marked improvement on the last few years. After the service Lord Derby, accompanied by members of the committee and other gentlemen, walked to the hospital and, with the Countess of Derby, made an inspection of the building, the house surgeons, Mr. J. A. Craig and Mr. G. R. Thompson, with Miss Mary Gordon, being among the guides. The wards were made bright by beautiful flowers which were presented by Mr. W. Gilbert Moss, a member of the committee. After the tour of the wards had been completed the following entry, made by his lordship and signed by him and the Lady Mayoress, was placed in the visitors' book:—"I have had great pleasure in visiting this hospital to-day. It gives every evidence of attention, skill, and good management. Notwithstanding the large number of patients everything seems to be done in an orderly and quiet manner, and it is interesting to see what kindly feeling seems to exist between the patients and nurses and other members of the staff of the hospital."

The Assizes: Drink and Murder.

Many years ago the late Mr. Baron Martin, who had often presided in the Crown Court at previous assizes, described a case of murder following a drinking bout as a "regular Liverpool case." Though fully twenty-five years have elapsed since that remark was made it is sad to find Mr. Justice Collins lamenting in his charge to the grand jury the many cases in the calendar which were plainly due to intemperance. Two cases of murder were tried on the 25th inst. each ending with a of verdict guilty and the dread sentence of death. In the first case the prisoner was a militiaman who had just been discharged from his annual training at Warrington. The deceased was a domestic servant to whom he had been paying attentions and whom he had treated with the greatest kindness up to the day which ended so fatally for her and so disastrously for him. On that day (July 29th) the prisoner, the deceased, and others were drinking together. One of the company, a married woman, let fall out of her pocket a razor which she had kept to prevent her husband doing harm to himself or anyone else. The prisoner picked it up and put it in his pocket, saying that he would take care of it for fear of danger. Later the prisoner, who had pawned his coat to pay for more drink, became annoyed because the deceased refused to come downstairs when he called her, and going up, he forced the door, dragged her downstairs, and with the razor cut her throat. The medical evidence showed that the wound must have been inflicted with considerable violence; there were two cuts penetrating to the spine, severing all the large vessels, and causing almost instantaneous death. Mr. Beamish, the medical officer of H.M. Prison, Walton, where the prisoner had been since his committal, stated that there were three depressions on the right side of his head and that such persons were more susceptible to drink than ordinary people. After he had received his death sentence the prisoner said: "Can I speak, may I have my body and head examined at the infirmary?" As the learned judge took no notice of this, the prisoner continued: "When I am hanged and finished with, will you let my body and head be examined at the infirmary, and put it in the paper what is to do with my head?" The other case was the sad ending to a court row in the city on Aug. 18th. The deceased and the prisoner were both working men and were drinking together when they quarrelled, the quarrel extending to their neighbours, and the row becoming general. The police stopped this, but next morning it was renewed, and ultimately the prisoner threw bricks from the top of his house at the deceased, who was leaning out of a window. One of the bricks struck the deceased on the head, and he fell out of the window on to the court below, a distance of thirty feet. On being taken to the East Dispensary, which was not far away, Mr. Leitch, the house surgeon, found him to be living, but he died a minute after his arrival. Blood was flowing from three wounds on his head. One of these divided the right ear entirely, the substance of the ear being jammed into the skull, which was fractured. There was a second wound on the back and near the top of the head, and beneath this a depressed fracture two inches in length. From this depression there was another fracture extending to the right out of the forehead. In charging the grand jury the judge observed that if the brick were thrown with the intent to do grievous bodily harm this was murder, and there was nothing to show such provocation on the part of the deceased as to reduce it to manslaughter.

The Murder of a Detective at Wigan.

Mr. Justice Collins tried to-day William Kearsly and Elijah Winstanley for the murder of Robert Kidd, a railway detective, on Sept. 29th last. The medical evidence was given by Mr. C. R. Graham of Wigan, who was called to the railway station on the night of the murder. He found the clothes of the deceased spattered with blood, his hands, face, and head were covered with blood, and there were nine incised or punctured wounds on the head, face, and right side of the neck, three being mortal wounds. One was below and in front of the right ear, and the other two were immediately lower down on the jaw and neck. The wounds were inflicted by a sharp instrument, such as the knife produced. The outside of the tip of the left index-finger was cut off also by a sharp instrument. Mr. Roocroft, police surgeon at Wigan, who made the post-mortem examination in conjunction with Mr. Graham, was of opinion that the deceased must have been on his left side when the fatal wounds were inflicted. Death resulted from hæmorrhage. The prisoner Winstanley's right thumb was swollen and bruised when examined three days after. The prisoner Kearsly had cuts across the back of the left little finger and the right middle finger, and scratches on other fingers. He was also bruised on the left arm, and there were other marks which, in his opinion, arose from direct violence two or three days previously. Both prisoners were convicted and sentenced to death.

Nov. 26th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary, Newcastle-on-Tyne.

FOR the important post of pathologist there are two candidates—Dr. T. Beattie and Dr. G. R. Murray. Dr. Beattie is one of the ablest medical graduates the University of Durham has produced. He has been educated entirely at Newcastle, and has recently left the Infirmary, where he filled in succession the offices of house surgeon and junior and senior house physician, in all of which he has given entire satisfaction. Dr. Murray studied in Cambridge, London, Berlin,

Digitized by Google

and Paris. He is a distinguished graduate in arts and in medicine of Cambridge. He has been in practice as a physician at Newcastle for five years. He is the Heath Professor of Bacteriology and Comparative Pathology and an Examiner for degrees in Hygiene in the University of Durham, and for some years has been the Pathologist to the Hospital for Sick Children in Newcastle. It is a source of great regret that the services of these two eminently well qualified men cannot be secured by the Infirmary on the present occasion. The election of one of them to the post of pathologist is watched with keen interest by the profession here. The great importance of the present appointment consists in the well-founded belief that whoever is fortunate enough to be elected will in all probability succeed to the next vacancy as full physician at the Royal Infirmary, and as, under present circumstances, a second vacancy cannot be expected for some ten years, one of these gentlemen must be excluded for a long term from office. Newcastle is fortunate in having two such candidates, and most unfortunate in not being able to secure the services of both.

Sub-warden of the University of Durham.

Archdeacon Watkins has been appointed to this important office in place of Professor Pearce, who succeeds the late Canon Whitley as rector of Bedlington. The University has now two very active church dignitaries at its helm. Dean Kitchin is the warden, and Archdeacon Watkins the sub-warden. One of these days, should it be legally possible, it is to be hoped the sub-warden may be a layman.

Tyne Port Sanitary Medical Officer.

Dr. Harper has received this appointment. He is a pupil of Dr. H. E. Armstrong and has quite recently vacated the office of house surgeon at the Royal Infirmary, in which capacity he gave great satisfaction and made numerous friends. It remains to be seen whether Dr. H. E. Armstrong will be offered the appointment of consulting medical officer to the Tyne Sanitary Authority and if so whether he will accept the post. It is certainly very extensively hoped that his connexion with the Authority may be continued. He has done most valuable work and deserves well of that body.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Laboratory of the Royal College of Physicians, Edinburgh.

THE Royal College of Physicians of Edinburgh has purchased property for the purposes of a laboratory. The premises at present occupied belong to the Royal Infirmary, and will shortly be required for infirmary extension. The property acquired is at the corner of Bristo-street and Forrest-road, and cost considerably over £7000.

Edinburgh Royal Physical Society.

At the opening of this society, last Friday, Dr. William Russell, the retiring vice-president, delivered an address on the Light Thrown on some Biological Processes by the Investigation of Disease. Professor Struthers occupied the chair.

Glasgow University.

The new anatomical and physiological laboratories for Queen Margaret College were formally opened by Principal Caird on the 18th inst.

Medical County Councillors.

Amongst the successful candidates in the recent election for the Lanarkshire County Council are Dr. Stewart, Carluke; Dr. John Cowan Wilson, Stonefield; and Dr. Jno. Colville, Motherwell.

Glasgow Medico-Chirurgical Society.

At a meeting of this society, on the 22nd inst., the principal business was a paper on Aprosexia, Convulsions, and Adenitis, dependent on Pathological Changes in the Faucial, Lingual, and Pharyngeal Tonsils, read by Dr. Walker Downie. A case of Gumma of the Iris was shown by Dr. Rowan; and Dr. C. O. Hawthorne showed three patients, members of a family, in which there is a history of Hereditary Syphilis, the patients manifesting varied evidences of the inherited taint. A number of photographs representing the teeth in inherited syphilis were also shown.

Philosophical Society of Glasgow.

Dr. Ebenezer Duncan, physician to the Victorian Infirmary, has been elected President of the Society. At a meeting of the Society held on the 20th inst. Professor Joseph Coats read a paper on Immunity to Infectious Diseases; a Pathological Study in View of Recent Researches.

West of Scotland Consumptive Hospital.

Some time ago a proposal to establish a hospital for the treatment of phthisis was made by a gentleman well known in philanthropic circles and prominently associated with homes for orphan and destitute children. At the recent annual meeting in connexion with these homes it was stated that a sum of over £12,000 had already been subscribed, but little or no information appears to have been given as to how this money is to be applied, or how the proposed hospital is to be managed. Dr. Ebenezer Duncan, in seconding the adoption of the report, stated that the deaths in Glasgow from pulmonary tuberculosis in 1894 numbered 1550, showing an increase over previous years. He calculated that there were in the city something like 15,000 sufferers from the disease, and expressed an opinion that it was the duty of the municipality to deal with so vast a public evil just as they dealt with the existence of other infectious diseases.

Glasgow Hospital Sunday.

At a meeting of the executive committee on the 20th inst. it was intimated that the sum received last year, which was the first year of a local Hospital Sunday, was £3640. Dec. 1st has been fixed as the day on which collections are to be made for the present year.

The Health of Greenock.

In the report of Dr. J. Wallace, the medical officer of health, for the five weeks ending Nov. 2nd it is stated that during that period the ascertained cases of infectious diseases numbered 399, of which no less than 366 were cases of measles. It is conjectured that at least one-third of these were without medical attendance. Since the outbreak of measles commenced in April 1345 cases have been reported; the fatal cases number 45.

Glasgow Coöperation for Trained Nurses.

This organisation, which was established with a view to secure for nurses the full financial return for their services, has now completed its second year and presents a very satisfactory report. The balance in favour of the coöperation is £72 11*s.* 6*d.* There are forty-six nurses on the staff, and it was stated at the recent annual meeting that one of these during the past year had earned £84, five had made from £70 to £80 each, four from £60 to £70, and the lowest sum earned by any nurse was £49. The management is in the hands of an executive committee composed partly of medical men and partly of nurses; there is a central home where the nurses reside when they are not employed.

Dundee Royal Infirmary.

At a meeting of the directors on the 21st inst. a letter was read from Mr. W. Ogilvey Dalgleish, of Errol Park, the chief partner of Messrs. Baxter Bros., Dundee, offering £3500 towards the erection of a nurses' home in connexion with the infirmary. The offer was gratefully accepted.

Nov. 26th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The New Hospitals for Infectious Disease for Dublin County.

I STATED some weeks ago my opinion as to the probable fate of the proposed scheme for the establishment of one or more large hospitals in the neighbourhood of Dublin for the treatment of infectious disease, and for closing all the existent city hospitals to typhoid and other fevers. The matter was fully discussed at a recent conjoint meeting of the Section of Medicine and State Medicine of the Royal Academy of Medicine in Ireland, after which Sir Charles Cameron, the originator of the scheme, promised to advise its abandonment in favour of the measures suggested at the meeting: viz—that a hospital for the treatment of epidemic small-pox or cholera outside the city be proceeded with, and that isolated convalescent homes be also established.

City of Dublin Hospital.

There have been many candidates for the surgeoncy to-

Digitized by Google

this hospital, vacant by the retirement of Dr. H. Fitzgibbon, including Dr. Charles Ball, who withdrew his name on his election to the Regius Professorship of Surgery to Trinity College. The Medical Board met on Nov. 22nd, and sent forward three names—those of Mr. Boyce, Mr. Johnson, and Mr. Gordon—to the general committee of the governors of the hospital, with whom rests the ultimate election.

Important Action against a Dublin Medical Man.

The case of Mason *v.* Hadden, of which a full notice appeared in the issues of THE LANCET of May 18th and 25th, and in which a verdict was given against Dr. Hadden of Rathmines for alleged negligence in having reported as small-pox a case which turned out to be of a different nature, the full Court of Exchequer, having decided that in their opinion there was no case to go to the jury, and that the plaintiff should have been non-suited at the trial, reversed to-day (Nov. 26th) the judgment against the defendant, and expressed their unanimous opinion that upon the evidence of the plaintiff's own medical witnesses there was no negligence. This decision will be hailed with great satisfaction, not alone by the friends of, and sympathisers with, Dr. Hadden, but by the profession at large, by whom the former verdict was looked upon as a most serious blow to the notification of infectious disease in Dublin.

Extension of the Ulster Eye, Ear, and Throat Hospital, Belfast.

I understand that the lease of the new ground has been received from the solicitors of the Belfast Charitable Society for signature, and that the foundation-stone of the main part of the extension is to be laid in January, 1896, just a quarter of a century since the foundation of the hospital, which was on Jan. 21st, 1871. The funds available for the new premises are beween £1400 and £1500.

The Condition of Ballyclare.

It would seem that the insanitary state of Ballyclare and the prevalence of typhus fever have occasioned the Antrim board of guardians considerable anxiety. They requested the Local Government Board to send down their medical inspector and engineer in order, if practicable, to devise some means of getting the town of Ballyclare improved, but in reply the Board stated that it was not their practice to send their inspector or engineer to inquire into such matters, and they said it was open to the guardians to obtain the necessary professional advice and assistance on the subject. The Antrim board of guardians, feeling their want of legal powers to ensure the isolation and disinfection of the typhus fever patients at Ballyclare, are to consider a notice of motion to adopt the Infectious Diseases Prevention Act of 1890. They have also resolved to suggest to the Local Government Board to send down their engineer to meet the guardians' engineer, in order to consult about and recommend some method to improve the present wretched sanitary state of Ballyclare, as they (the guardians) have already adopted the best scheme recommended by their own engineers which the Local Government Board have refused to allow to be executed.

Sad Death of Mr. W. J. Kisby, L.F.P.S. Glasg., L.A.H. Dub.

An inquest was held on Nov. 22nd with reference to the greatly lamented death of Mr. Kisby, medical officer of Corduff Dispensary, Carrickmacross Union, which occurred on Tuesday night, Nov. 19th. It would appear from the evidence that after going to bed on that night two messengers came with a "red ticket" (urgent) for him to attend a poor dispensary patient at her confinement. Getting up, Mr. Kisby took an umbrella and a lamp (the night being dark and stormy) and set out, having previously sent on the messengers with his obstetric bag. Two hours later the men returned who had come for him to say that the poor woman was better and that he was not wanted. Mr. Kisby's wife, becoming alarmed that her husband had not appeared at the sick woman's house, set out early in the morning with a neighbour, and was horrified to find her husband's body at the bottom of a drain nine feet deep. From the medical evidence it seems that there was a large wound extending from the bridge of Mr. Kisby's nose to behind the left ear, leaving the bone bare, with an extensive fracture of the skull. It would appear that at a short distance from his house, he turned off from the principal road into a by-road leading to the place where the woman was ill, and after going a short way he must have missed his footing and fallen into a stream (where his body was found) flowing at the side of this lane. The night was very stormy, and the [illegible] which he was carrying was probably extinguished. It [illegible] that there is a great want of proper fences along the [illegible] in this district, and it is said that a short time ago [illegible] men owing to this cause lost their lives in the neighbourhood by falling into a boghole. It was ascertained this [illegible] eight feet below the level of the road there was a projecting sharp stone with blood on it, and in his fall Mr. Kisby's head seems to have struck this, and in this way he received the very serious head injuries which alone probably caused death, though the end may have been hastened by the fact that the body was found lying face downwards in the water. Mr. Kisby was fifty-one years of age, and the greatest sympathy is felt for his bereaved wife and children.

Belfast Royal Hospital.

At the quarterly meeting of the Belfast Royal Hospital held on Nov. 25th, it was stated that at the end of the year the hospital was in debt to the amount of £846 [illegible]. Dr. Houston was appointed house surgeon for the [illegible] department in place of Dr. Whitaker, promoted to the [illegible] work.

The Samaritan Hospital.

A strong appeal is made in the Belfast papers for [illegible]—say £500—to build a spacious ward at the rear of the Samaritan Hospital for the accommodation of advanced [illegible] cases.

A Case of Small-pox at Ennis.

A police-sergeant named Dunlea has been removed to the Ennis Union Fever Hospital suffering from small-pox, and active measures have been taken with a view to prevent the spreading of the disease. The clothes and bedding [illegible] been burned, and the room that had been occupied by the patient at the barracks has been disinfected and locked up. Mr. Greene, medical officer of Ennis Dispensary, informed the guardians he thought there was no doubt it was a case of small-pox. Dr. Clements, medical inspector of the Local Government Board, was sent to make inquiries and render all the assistance in his power to the local authorities. He found the patient progressing very satisfactorily, and neither he nor Mr. Greene has been able to trace the source of contagion. The other constables in the barracks are kept under strict observation in order that any other cases which they occur, may be dealt with promptly.

Cork Young Men's Society.

Last Tuesday evening Dr. Henry Corby, Professor of Midwifery in Queen's College, Cork, delivered a lecture to the society, wherein he ably traced the rise of commercial prosperity in different nations to the amount of attention paid by the nation to technical education.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Materia Medica and Therapeutics: the Old and the New.

A PRACTITIONER of, say, twenty-five years' standing who had happened to stray into the amphitheatre of the Paris Faculty during the delivery of Professor Landouzy's opening lecture on the above-named subject would probably have been considerably surprised at the matter thereof. For sero-therapy only was spoken of, and, what is more, it was announced that sero-therapy and its therapeutical applications would form the subject of Professor Landouzy's winter course of lectures to the exclusion of the current medication by means of drugs. After passing in review the deplorable state of surgery in the pre-Listerian epoch—a state which his old master Denouvilliers summed up in this significant and warning sentence, "Quand vous aurez une amputation à faire, regardez-y à [illegible] fois, car, quand nous décidons d'une opération, [illegible] souvent nous signons un arrêt de mort"—Professor Landouzy evoked the glorious memory of Pasteur and the fecund practical genius of our own Lister, who, working towards the same end, made surgery the marvellous science it now is. Nélaton once remarked that whoever succeeded in "delivering us from pus" deserved a golden statue, and assuredly these immortal co-workers merit such a recompense. Pushing his researches [illegible] Pasteur opened up the path of sero-therapy [illegible] Kitasato, and Maragliano.

Digitized by Google

of Pasteur is to have invented a method which touches the *pourquoi* of disease more closely than any other known method. Alongside of sero-therapy, Professor Landouzy stated that opo-therapy (ὀπός, juice) — a method due to the late Brown-Séquard's insight into the value of the internal secretion of glands — would be considered in its details. But, believer as he is in the future of sero-therapy and opo-therapy, Professor Landouzy warned his audience of the impotence of any such methods in the treatment of disease accompanied by spoilt or degenerated organs. Here the *rôle* of the observant, watchful, and resourceful clinician will find full scope in enabling the sufferer to live on good terms with an incurable lesion of such vital organs as the heart or the kidney.

The Treatment of Orchitis at St. Louis Hospital.

The method of treatment adopted by Dr. Du Castel at the Hôpital St. Louis of this common and painful affection is as follows. The scrotum is exposed to a spray of methyl chloride, and the testes are then supported by an ordinary suspensory bandage, which covers a layer of cotton-wool, itself covered by a sheet of oiled silk. Every other day the process is repeated, the patient taking ordinary exercise in the intervals of the dressings. The average duration of the treatment is from twelve to fifteen days, considerably shorter than under the old antiphlogistic *régime*, which kept the sufferer on his back for several days.

The Collége de France.

The winter session at this venerable institution will open on Dec. 2nd. It may interest your readers, in whose minds the College is intimately associated with such workers as Claude Bernard, Marey, Ranvier, and Brown-Séquard, to know the subjects of the courses of lectures delivered within its walls. I therefore transcribe them. Medicine—M. d'Arsonval (the successor of M. Brown-Séquard): The Medical Applications of Electricity. Natural History of Organised Bodies—M. François-Frank (for M. Marey): Experimental Criticism of Published Works bearing upon the Innervation of Blood-vessels. Comparative Embryology — M. Henneguy: The Genesis of the Reproductive Elements. General Anatomy—M. Ranvier: Experimental Studies on the Regeneration of Tissues. Experimental and Comparative Psychology—M. Pierre Janet (for M. Th. Ribot): The Psychological Conditions of Personality. Persons who have not pushed their wanderings for some few years as far as the neighbourhood of the Collége de France would now hardly recognise the locality. Ancient houses that stood there only three or four years back have been replaced by palatial constructions such as the new Sorbonne, the Académie des Sciences, and the new Lycée Louis le Grand. Facing the Boulevard St. Germain aspect of the College there is still standing the statue of Claude Bernard, no anti-vivisectionist iconoclast having as yet dared to attempt its destruction. In the small garden close by is the bronze statue of Voltaire, whose cynical expression contrasts forcibly with—*pardon, mesdames les anti-vivisectionnistes*—the benevolent look of Claude Benard.

The Mortality from Tuberculosis in the Towns of France.

In his work "Le Phthisique et son Traitement Hygiénique," Dr. Petit gives the following figures relating to the ravages of tuberculosis amongst the urban populations in this country. The table is based upon the statistics of 662 towns.

Towns.	Population.	Mortality (tuberculous) per 100,000 inhabitants.
In 11	100,000 to 430,000	363
,, 46	30,000 ,, 100,000	305
,, 50	20,000 ,, 30,000	288
,, 127	10,000 ,, 25,000	271
,, 332	5,000 ,, 10,000	216
,, 95	below 5,000	181

The preceding figures bring into relief the influence of agglomeration. In Paris the proportion of deaths from this cause is 490 per 100,000 inhabitants. In the department (of the Seine) in which it stands, and whose population numbers over three millions, the average mortality from tuberculosis, traversing the period comprised between 1889 and 1893, is 14,565.

Photographic Passports for Paris Practitioners.

A practice already in operation in Berlin and in certain cities of the United States is about to be adopted in this capital, the Prefect of Police having consented in deference to a wish expressed by the Council of the Medical Societies of the Arrondissements of Paris. Each practitioner registered in the official list published by the Prefect of Police will have delivered to him a card of identity, containing on one side his photograph and on the other his name and address together with the certificate of the Prefect. This card, shown to a policeman, will suffice to procure for the holder facilities of circulation within Paris denied to the ordinary base mortal. In order to obtain this card, medical men who are members of any *société d'arrondissement* may send their names and addresses *plus* the sum of 1 fr. 25 centimes to the secretary of their society. Non-members must apply to the general secretary of the Council of the Societies. A notice will appear later specifying the days on which the applicant may undergo the painful process of photography at the hands of M. Pirou. An anæsthetic would be a comfort during the *pose*.

Nov. 26th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Diphtheria of the Skin.

THE following rare case is described in the *Berliner Klinische Wochenschrift* by Professor Flesch of Frankfort. A girl, aged two and a half years, was scalded with boiling water on Aug. 3rd, nearly the whole left side from the lips to the umbilicus being involved. On the places where the clothes had retained the hot water the effect was very severe, whilst it was superficial on the face and neck. The whole of the injured surface was covered with 2 per cent. salicyl vaseline and cotton wool, the dressing being changed daily. The child on the first evening had a temperature of 39·6° C., but felt quite well the next day. On the seventh day the superficial scalds of the neck and face were covered with fresh epidermis, so that the dressing was no longer necessary there, and the mother, overjoyed at this improvement, kissed the girl's neck just on the limit where the deep wound was beginning to granulate. On the following day the mother suddenly complained of pains in the throat, and in the evening an obviously diphtheritic inflammation of the tonsils was visible. She and the child's aunt, who was seized with the same disease, were therefore isolated, and the child's father, who felt ill the following day, had apparently a slight sore-throat, the diphtheritic nature of which was very probable. Both ladies were treated with injections of Behring's anti-toxin and subsequently developed hæmorrhagic nephritis, but quickly recovered. On Aug. 13th the spot where the child had been kissed showed a very remarkable alteration. The skin was covered by a grey mass and was much swollen, the œdema extending as far as the eye, while the edge of the spot was irritated and somewhat elevated. The child was, therefore, treated with Behring's antitoxin, and on bacteriological examination of the grey mass Dr. Benario found an abundance of Löffler's bacilli and cultivated them on agar. On the third day the grey mass disappeared, together with the œdema, but was replaced by an ulceration, which healed after a short time. Some time afterwards a slight paresis of the palate appeared, but there was no other complication, the throat of the child being unaffected. Professor Flesch states that diphtheria of the skin usually occurs only in the neighbourhood of tracheotomy wounds, and is very rarely found in other parts. As the diphtheria attacked the new epidermis but spared the granulations he concludes that the moist granulations hindered the disease from spreading over the whole surface of the body, but that newly-formed epidermis is favourable to the growth of Löffler's bacilli.

The Influence of Antitoxin on the duration of Laryngeal Intubation.

Dr. Bókai of Budapest has published statistics showing that the duration of laryngeal intubation is shortened by the use of antitoxin. He successfully treated 215 intubated cases without antitoxin, the average period of intubation being seventy-nine hours. Since the introduction of the antitoxin treatment he has had 45 successful cases of intubation, the average duration of which was sixty-one hours — being a reduction of eighteen hours.

Honours to Professor Lewin.

Professor Georg Lewin, the senior of the Berlin syphilographers, on Nov. 12th celebrated the fiftieth anniversary of his nomination as M.D., and in honour of the event the

Digitized by Google

Berlin Dermatological Association, of which he is the chairman, held a special meeting at which a congratulatory address was read by Professor Lassar, the vice-president of the association, and a collection of twenty-two treatises, written for that purpose by former and present assistants and pupils and other friends of Professor Lewin, was presented to him. The principal essays were: on Syphilophobia, by Dr. Benda; on Gummata of the Eye, by Professor Hirschberg; on the Principles of the Treatment of Eczema, by Professor Lassar; on the Relations between Hereditary Syphilis and Nervous Diseases, by Professor Mendel; and on Piedra Nostras, by Professor Unna. Professor Virchow read a paper on the Antiquity of Syphilis, mentioning that very remarkable alterations of the bones had lately been found both in Egyptian mummies and in the figures on pottery made by American races before the time of Columbus. Professor Leyden then read a paper on the Internal Complications of Gonorrhœa, and after the meeting there was a social gathering in Langenbeck House.

Nov. 25th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The New Istituto Clinico at Pisa.

OF all the Italian medical schools, that at Pisa boasts (at least in the century now drawing to a close) the greatest number of English-speaking graduates. This fact, taken in connexion with its European renown under the Medici (particularly Lorenzo and Cosimo) and its having produced in Galileo a pioneer, conjointly with Bacon, of the modern inductive method, would of itself suffice to interest your readers in yesterday's ceremony—the inauguration of a new clinical institute in furtherance of the efficiency of the school. Its indefatigable professor of clinical medicine, Dr. Giovanni Battista Queirolo, has subscribed largely to this new foundation, and to him, aided by the "Consorzio Universitario" and the munificence of King Humbert, it owes its completion as one of the best cliniques in the peninsula. This adjunct to the resources of Pisa comes not a moment too soon. Italy is on the eve of passing a law which will sanction the struggle for existence among her Universities in general, and her medical schools in particular, and Pisa, if only to keep abreast of younger, and in some respects better-circumstanced, rivals, requires as a *conditio sine quâ non* a clinique worthy of the stage now reached by the healing art. I will only add that the amphitheatre of the institute, which (so to speak) "crowns the edifice," is commodious, finely proportioned, and well adapted both for lecturer and auditory, while the ornamentation, contributed gratuitously by the ablest artists of Pisa, culminates in a very fine bust of Morgagni, the "creator of pathological anatomy." May the work of the clinique be carried on in the spirit and with the success of its *genius loci*.

The Disinfecting Establishment in the Aventine.

We have now, in a completed state and in working order, what has long been a desideratum in Rome—a special establishment for the disinfection of wearing apparel and all such articles as may be contaminated by infective or contagious diseases. Annexed to the Lazzaretto di Santa Sabina on the Aventine, it was instituted by way of experiment in 1893 for the instruction of the *personnel*. Last year it added to its resources a crematory furnace, constructed from the designs of Professor Angelo Celli, for the destruction of all such articles as could not be sterilised. The whole establishment, which for some months had been in a state of suspended animation, has now come under the supervision of Professor Mario Panizza, of the Public Health Department, and may be regarded as another safeguard for the Roman population, resident and migratory, against the risks of infective disease.

Health of the Red Sea Colony, Civil and Military.

"Eminently satisfactory" is the official report from Massowah as to the health of soldier and civilian in the Colonia Eritrea. There are only ten patients in the civil hospital at Massowah, none of them seriously ill, and some approaching convalescence. In the military hospital, where all the patients of the garrison are accommodated besides those belonging to the section for non-combatant natives, there are forty under treatment for various maladies, fourteen of them being syphilitic cases and six suffering from traumatic lesions. No case of epidemic disease has been reported throughout the entire colony.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Reappearance of Cholera in St. Petersburg.

RUMOURS that cholera had reappeared in St. Petersburg have been current for the past three or four weeks, and they are now confirmed by an official announcement from the municipal authorities. The earliest cases of sickness suspiciously resembling cholera occurred on Oct. 10th (22nd). Between that date and Oct. 25th (Nov. 6th) there were 27 such cases with 12 deaths. The following are the statistics of the outbreak up to the present:—

				Cases.	Deaths.
From noon on	Oct. 25th	to noon on	Oct. 26th	—	1
,, ,,	Oct. 26th	,, ,,	Oct. 27th	3	—
,, ,,	Oct. 27th	,, ,,	Oct. 28th	2	2
,, ,,	Oct. 28th	,, ,,	Oct. 29th	2	—
,, ,,	Oct. 29th	,, ,,	Oct. 30th	8	3
,, ,,	Oct. 30th	,, ,,	Oct. 31st	6	5
,, ,,	Oct. 31st	,, ,,	Nov. 1st	4	1
,, ,,	Nov. 1st	,, ,,	Nov. 2nd	2	2
,, ,,	Nov. 2nd	,, ,,	Nov. 3rd	5	3
,, ,,	Nov. 3rd	,, ,,	Nov. 4th	6	2
,, ,,	Nov. 4th	,, ,,	Nov. 5th	5	5
,, ,,	Nov. 5th	,, ,,	Nov. 6th	6	1
,, ,,	Nov. 6th	,, ,,	Nov. 7th	4	2
,, ,,	Nov. 7th	,, ,,	Nov. 8th	9	2
,, ,,	Nov. 8th	,, ,,	Nov. 9th	2	3

(All the dates in the table are Old Style dates.)

At present there remain under treatment 28 cases with choleraic symptoms. These cases are distributed in the Alexander Hospital in memory of Botkin, the Obuchovski, the Petropavlovski, and the Mary Magdalene Hospitals, and the Hospital in memory of the Emancipation of the Serfs.

St. Petersburg, Nov. 10th (22nd).

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Medical Department of the National Guard.

THE special committee of surgeons appointed to discuss the needs of its medical department and make suggestions decided not to concur in a recommendation that the medical corps be made a separate organisation. It was proposed, however, to increase the number in the hospital corps to twelve for each regiment, six for battalions, and two for separate companies. Of the twelve in the regimental corps three are to rank as corporals and two of the battalion corps likewise. It was decided to recommend that each of the corps be provided with an instrument case and a revolver, and each corps with a surgical and medical outfit. It was voted that to procure competent hospital stewards they be paid $50 a year in addition to pay for duty.

Use of Intoxicants.

The *Journal of Inebriety* estimates the total number of drunkards in America at 1,600,000. There being about twenty-five millions of adults in this country, this means that one person out of every fifteen drinks to excess, and is consequently more or less of a drunkard. The journal thinks that this estimate is a very modest one and rather under the mark than above it.

Suits for Damages against a Railroad.

Over sixty suits for damages, aggregating nearly $1,000,000, have been begun against the New York and Sea Beach Railroad by sufferers in the wreck on the road on Labour Day, when about seventy people were injured. The first suit is for $25,000 damages. Another action is that of a family, the father of which died from his injuries a week after the accident. The sixty suits call for damages in varying amounts. The lowest is for $2000. There are a score of plaintiffs who demand $5000, and as many more who think that $10,000 is none too much to make them whole. The road's defence will be that it was not guilty of negligence, and therefore not responsible for damages.

Diminished Number of Immigrants.

The Superintendent of Immigration reports a marked diminution in the number of immigrants during the past year. The total number of steerage passengers landed at this port during 1894-95 was 216,724, which was only 14,987

Digitized by Google

less than the total number landed during the previous year (231,711), but the decrease in the number of alien steerage passengers landed amounted to 28,118. The cause, he states, is to be found in the correspondingly larger number of United States citizens who returned in the steerage during the fiscal year 1894–95 (25,796) than in 1893–94 (12,665). He recommends that the inspection be extended to cabin passengers and to all vessels from foreign ports without exception. He also recommends increased accommodation of the immigrants at quarantine.

Nov. 19th.

Obituary.

ROBERT JAMIESON, M.D., L.R.C.S. EDIN.,

CONSULTING PHYSICIAN, ROYAL LUNATIC ASYLUM, ABERDEEN.

BY the death of Dr. Robert Jamieson on the morning of Nov. 17th Scotland has lost her oldest asylum superintendent. A gentleman much esteemed in the locality, of marked intellectual power and independent character, with handsome physical appearance, firm in discipline, but with genuine kindliness of heart, Dr. Jamieson was an ideal asylum superintendent, and in the course of a long life must have had a strong influence for good. Dr. Jamieson was born in Aberdeen in 1818, and was the son of a leading jeweller in the city; he became M.A. Aberd., M.D., L.R.C.S. Edin. in 1839; was appointed medical superintendent of the Royal Lunatic Asylum, Aberdeen, in 1840, but on his marriage in 1846 resigned and engaged in private practice; he was at this time Lecturer on the Practice of Medicine and Medical Jurisprudence and Medical Examiner for Degrees, King's College, Aberdeen; in 1853 he was unanimously re-elected superintendent of the asylum, with accommodation according to his requirements, and held the post till, in 1881, Dr. William Reid was appointed his coadjutor; but the weight of years telling rapidly on his seemingly stalwart frame, he was released from all active responsibility in 1884, but remained in his previous residence as consulting physician. On his appointment as superintendent in 1840 the daily number in residence at the asylum was 144; at present it is 730; and the history of the asylum presents a continuous series of enlargements and improvements, evidencing the increasing care bestowed on the comfort of those mentally afflicted, as also the increase under our modern civilisation of this class, the improvements being never more marked than at the present moment, when the extensive buildings of the new hospital just await completion. In a contemporary notice we find him credited, together with Dr. Hutchings of Glasgow, with introducing the non-restraint system of treatment in Scotland; but that he was no mere theorist his own words from his first report in 1841 will show: "In regard to the subject of coercion we find ourselves called upon, in justice to the managers and to the friends of the patients under our charge, to make a short statement of our practice in this important particular, and it shortly is this, that we act on the principle of *non-restraint* as far as the construction and economy of the establishment will allow; but we have no desire to obtain the notoriety of being non-restrainers at the expense of what we conscientiously deem to be for the safety and advantage of our patients. That there are cases in which mild restraint is both judicious and humane every physician who is unprejudiced must admit who has ever witnessed the unbridled violence of an outrageous maniac exhausting the excited vigour of an enfeebled constitution and extinguishing the hope of recovery for ever. We have no more hesitation in such cases, when other means have been useless, in applying the waist-belt or the muff than we would have in applying leeches or a blister against the will of the individual. ..... It is scarcely requisite, now that the public mind entertains less prejudiced notions on the treatment of the insane, to notice that threatening and abusive language and harsh measures of every description are not only found to be unnecessary but are strictly prohibited among the attendants and made the occasion of reprimand or dismissal when discovered." As Lecturer on Medical Jurisprudence at King's College Medical School Dr. Jamieson devoted eight lectures to insanity, commented on at the time as remarkable for their fulness and ability. These appear in the *London Medical Gazette*, 1850, and will well repay the attention of the specialist. His lecture on the opening of King's College Medical School, 1850, may also be perused with both profit and pleasure. A discourse on Mind and Body,[1] read before the Philosophical Institute of Aberdeen, shows him dealing with his subject in a more popular manner, and in especial evidencing a regard for higher considerations than those merely physical. Dr. Jamieson was predeceased by all his family. Known privately as a gentleman of cultivated tastes, with special musical talent, he had the personal ambition in early life to become a painter. He was a liberal patron of Scottish art, of which his valuable collection is testimony, and had himself sat to three Academicians—Sam Bough, John Pettie, and Sir George Reid.

MEDICAL TRIAL.

THE trial of George Wight, M.B. Edin., charged with the manslaughter of Gertrude Fanny Fletcher at Holloway, was heard at the Central Criminal Court on Monday and Tuesday last before Mr. Justice Wright.

Defendant pleaded "Not Guilty."

Mr. Charles Mathews, Mr. Biron, and Mr. H. T. Hewitt conducted the prosecution; Mr. Carson, Q.C., Mr. Geoghegan, and Mr. Bruce defended.

Mr. Mathews, in opening the case, outlined the details which were elicited at the inquest at Folkestone (reported in THE LANCET of Sept. 28th) and at the police-court proceedings. Witnesses were called on the part of the prosecution, and the Treasury evidence was concluded on the first day of the trial. On Tuesday Mr. Mathews summed up the case for the prosecution, no witnesses being called for the defendant. He contended that Dr. Wight was not in a fit condition to deliver the woman when he attended the deceased. Dr. Wight was grossly, and therefore culpably, and therefore criminally, negligent in the performance of his duty. Be it granted that there was an error in attributing the prisoner's condition to drink. The prisoner in his evidence before the coroner said that he was suffering from giddiness and swimming in the head and that he took bromide on the Saturday; that at 2 o'clock on the afternoon of Sunday, Sept. 8th, he took a strong dose of chloral; and that on that Sunday when he attended he might have been suffering from the effects of the chloral. If a man were not in a condition to perform his duty, and that unfit condition was produced by his own act, although morally they might draw a distinction between a man suffering from the effects of drink and a man suffering from the effects of other narcotics, the criminal responsibility was not changed.

Mr. Carson, Q.C., for the defence, said that he was pleading the cause of a man who for thirty years had practised his profession with skill and distinction and who by his kindness to his patients had won the hearts of all who knew him. He denied that there was any negligence on the part of Dr. Wight. Dr. Wight had had very great experience in midwifery, having attended 5000 confinements. Each of the medical witnesses had stated that the prisoner had had very great experience and that he was thoroughly well acquainted with the use of instruments. The medical evidence had shown that if the forceps slipped, it might cause the injury. If the injury was not caused by negligence but by the accidental slipping of the forceps, then the jury ought to return a verdict of "Not Guilty." With regard to Dr. Wight's condition at the time, no one seriously believed that he was under the influence of drink. The nurse who was present did not say that he was under the influence of drink, and none of the medical men said that he was under the influence of drink. The latter permitted him to take part in the operation of delivering the child. Dr. Wight suffered from insomnia and took narcotics for the purpose of inducing sleep. If a man had to take medicine to improve his physical condition and anything happened afterwards in the conduct of his business, the man ought not to be held criminally responsible. Mr. Carson, in view of the medical testimony, denied that there was any evidence on which to base a charge of criminal negligence.

Mr. Justice Wright, in summing up, remarked that it might be quite right for a man to stupefy himself with chloroform, chloral, or similar medicine for the treatment of disease, but if he did so he must not while in that state take a case of childbirth.

The jury returned a verdict of "Guilty."

Mr. Carson said he had a number of letters from patients of Dr. Wight, all telling the same tale as that which had been related of the devotion and attention to his patients. He need scarcely remind his lordship that Dr. Wight's position and means of livelihood had been entirely destroyed, so that he had already been to a large degree punished. He had a large family, and there was the fact that an action claiming damage arising out of the same matter had been commenced by the husband of the deceased. That action was practically determined by the verdict in this case, and the accused was anxious to settle that action, and to compensate the husband. Under these circumstances, would his lordship feel justified in postponing sentence until next sessions, in order that the civil action might be settled.

Mr. Justice Wright thought there was no ground for postponing sentence.

Mr. Frederick R. Hannah, L.R.C.P. Edin., was called and gave evidence as to the accused's health.

Mr. Justice Wright, in passing sentence, said the jury had discharged a very painful duty, and the one he had to perform was not less painful. He must deal with the case in the first instance entirely on legal and public grounds, and the sentence which he must pass must be a substantial one. If the case had arisen from intoxication, or if the maltreatment of the patient, such as the jury very properly found proved in this case, had resulted from intoxication, a sentence of not less than probably a year's hard labour would have been passed. This was a different case, and he should sentence Dr. Wight to three months' imprisonment. Having regard, however, to the obvious consequences and the absence of bad intention on the part of Dr. Wight, he should not order hard labour. He should direct that until the instructions of the Secretary of State for the Home Department were received the prisoner should be placed under the care of the medical officer of the prison.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE fifty-ninth session of the General Medical Council was opened on Tuesday last under the presidency of Sir Richard Quain and with unwonted surroundings, for the Council are meeting this year in the buildings of the Royal College of Physicians of London pending the completion of the building arrangements of their own home in Oxford-street.

With regard to these same arrangements the Council do not appear to be in a very happy position. The freehold of their premises had been purchased, the new designs had been approved of, and the architect had entered into negotiations with the owners of the adjoining premises for the purpose of arranging the contemplated alterations, and all appeared to be going well. When the contract had been signed, when the building proceedings were well under way, when the chief surveyor of the Office of Works had inspected the premises and stated his readiness to report favourably as to the interference by the building with the occupant of 16, Hanover-square, there was found on a copy of the sub-lease to the tenant of the same house, in addition to the conditions safeguarding the usual rights and privileges, an exceptional clause providing that the Office of Works must not "increase or permit to be increased the height of the building situate at the rear of the messuage or demesne or premises hereby demised now occupied by the Council of Medical Education ..... without the consent in writing of the said tenant." Thereupon the Council were informed that permission could not be given to them by the Office of Works to make the proposed alterations save after arrangement with the tenant. The negotiations with the tenant having failed, the plans have now been modified, and though the amended building may not be as architecturally acceptable as the original design had promised, its warming and hygienic arrangements should be perfect, as they have been supervised for their fellow councillors by Dr. R. Thorne Thorne and Mr. Teale.

We congratulate the President upon his vigorous appearance. Sir Richard Quain having recently made public allusion to his age, we make bold to compliment him upon his brightness and alertness in the chair and upon his close grasp of the subjects brought before him at the deliberations of the Council.

Tuesday's proceedings were marked by the unqualified rejection by the Council of the motion, proposed by Sir W. Foster and seconded by Mr. Wheelhouse, that the resolution of the British Medical Association, to the effect that direct representation of the profession on the General Medical Council should be increased, should receive some notice at the hands of the Council. There were found to support Sir W. Foster and Mr. Wheelhouse only five other members of the Council.

Wednesday's proceedings were largely made up of a debate upon the position of the Conjoint Board of the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Dublin. It will be remembered that in June last Sir Dyce Duckworth, Chairman of the Examination Committee, presented a report on the examinations of this Board (now defunct save for the use of some few recent students), whose tenour may be indicated by the fact that he asked the Council to find that the standard of proficiency in medicine was insufficient. This motion was carried by 17 votes to 4, and a representation upon the strength of it was made to the Privy Council. The Privy Council having put certain queries to which the General Medical Council have replies ready, a motion by Dr. MacAlister was adopted to the effect that the Privy Council should be informed that as long as these examinations are deemed "qualifying" under the Medical Act, the General Medical Council will be unable to maintain a due standard of proficiency save by repeated inspection.

TUESDAY, NOV. 26TH.

Sir RICHARD QUAIN, Bart., President, in the chair.

Opening of the Session.

The General Medical Council met in the hall of the Royal College of Physicians of London in Trafalgar-square, this being their fifty-ninth session. There was almost a full attendance of members, Dr. Haughton and Dr. Kidd being the only absentees.

The President's Address.

The PRESIDENT (Sir Richard Quain) in formally opening the session commenced by expressing his sense of the indebtedness of the Council to the Royal College of Physicians of London for the readiness and courtesy with which they had offered the use of their Library. He then briefly stated the reason for the delay in the improvements at the Council's own premises, which, he stated, were due to the fact that the plans could not be carried out without arrangement with the tenant of 16, Hanover-square, with whom negotiations so far had failed.

"I have pleasure (Sir Richard Quain continued) in informing the Council that considerable progress has been made in the preparation of the new edition of the British Pharmacopœia. The members of the Pharmacopœia Committee met on three days in July (24th, 25th, and 26th), and on two during the current month (22nd and 23rd). The several valuable suggestions made by the medical authorities in this country have been carefully considered, including points of construction in the Pharmacopœia, alterations in the various classes of preparations, as well as in many individual preparations. The whole of the large number of suggested additions and omissions have been considered. The suggestions of the Indian and other colonial authorities have also, so far as possible at present, been dealt with. A committee of the Pharmaceutical Society has aided, and is aiding, the Council in the production of the work. The editor reports satisfactory progress in all its sections, some portions of the work having been already set in type, printed, and placed before the Pharmacopœia Committee. The co-operation of referees, as stated in the report of the committee in June last, has been invited and cordially rendered. In pharmacology, Dr. Lauder Brunton, Professor Fraser, and Dr. Walter Smith are prepared to render their assistance; in chemistry, Dr. Thorpe, with Professors Tilden and Emerson Reynolds; and in botany, Mr. Thiselton-Dyer and Mr. Holmes. We may thus anticipate that though the period for the production of the Pharmacopœia may be somewhat postponed, the delay will be compensated for by satisfactory results.

I have caused to be printed, for the convenience of the Council, in a separate form important documents in connexion with the Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries' Hall of Ireland, which include the representation made by the Council to the Privy Council on the subject of deficiencies in the examinations of this Board, together with the observations on the subject addressed to the Privy Council by the College and the Hall: also a letter from the Lord President of the Council, in which his Grace points out that, the Conjoint Board having ceased to exist, it was unnecessary to take further action in the matter. A further communication to the Privy Council, from the secretary of the late Board, has indicated the apparent necessity for a continuation of the proceedings of the Board for the examination of candidates who might, by their previous arrangements, have a claim to be examined. The opinion of the legal advisers of the Council will be submitted, together with the documents. It will be seen also that the Apothecaries' Hall of Ireland, regarding the Conjoint Board as having ceased to exist, makes an application to the Council for the appointment of assistant

Digitized by Google

examiners in surgery in accordance with the provisions of Clauses 3–5 of the Medical Act, 1886."

[Sir Richard Quain then briefly referred to the penal cases, which happily on this occasion are but few, and then passed to the real gist of his address an exposition of the duties and limitations of the Council. He continued :]

"Communications, which will be found in the programme of business, have been addressed to the Council on matters in which the constitution and functions of the Council are concerned. It seems to me that, in my capacity as President, it is my duty to notice, however briefly, some of the suggestions which, not for the first time, have been made in regard to these subjects. For instance, it is suggested that an increased number of direct representatives of the medical profession should be elected on the Council, and that certain functions, in which such direct representatives would have a special interest, might then be assigned to, or undertaken by, the Council.

Firstly, with reference to the functions of the Council, we must remark that this Council is the creation of the Crown, acting on the advice and with the consent of both Houses of Parliament, as expressed in the Medical Acts, and created primarily in the interests of the public to secure for that public competent professional aid. The protection of the interests of the public is the first duty assigned to the Council, as instanced by the means taken to secure the efficient education and competent skill of the members of the medical profession.

The Council has also had assigned to it the duty of forming an accurate register of competent practitioners and of keeping that register free from all unworthy elements. The Council has also the duty of preparing and publishing the British Pharmacopœia. There are many very estimable persons who would call on the Council to undertake other duties, such, for example, as taking cognisance of matters of professional etiquette and improper conduct and action, whether in relations of the profession to the public or amongst members of the profession itself, and without question many of these grievances may be deserving of investigation and censure. The duty of investigating the subjects to which I refer should come under the notice of the licensing authorities which have conferred the licence to practise on the individual complained of. Several of these bodies can, and do, exercise these controlling powers, and what some do all should be induced to do. By this action on the part of the medical authorities, by putting in force their by-laws and regulations, many of the grievances which our profession justly complain of might be remedied. The duties of the Council are of a far higher and a more important character, which promise every year to become of yet greater public importance, and I am satisfied that were the Council to interfere in these matters of ethical detail it would but lose its authoritative influence with the Government and would give only doubtful satisfaction to the public.

Secondly, with reference to the *constitution* of the Council, an argument in favour of the election of additional direct representatives is deduced from the practice of, amongst other bodies, the Incorporated Law Society. Now, it must be observed that this society, which is very similar in its constitution to the British Medical Association, though chartered, is a purely voluntary association, comprising amongst its members only a portion of the qualified practising solicitors. They each subscribe one guinea per annum. This body can, and does, institute inquiries into the conduct of members of the profession against whom complaint has been made by any member of the public; if the council of the Society is satisfied that a case is made out, they appear in support of it before a Common Law judge, who gives a decision upon it. This system contrasts very much in favour of our Council, which is itself empowered to investigate charges made against delinquent members of the profession, and itself to pass upon them a judgment from which there is no appeal. It is said in favour of the election of additional direct representatives that the medical practitioners, who contribute by their registration fees to maintain the Council, should have a larger share in its constitution. Again, a comparison may be made with the profession of solicitors. Solicitors pay large apprenticeship fees, and they have to render prolonged unpaid service to the solicitors to whom they are articled, they pay fees for education and examination, and, before being admitted to practise, they are required to pay stamp duties to the Inland Revenue authorities amounting to £110. They also pay annual fees for a licence to practise in London of 9 guineas each, and for the privilege of practising in the country of 6 guineas each. Observe that over the expenditure of these contributions they have no control whatever. The facts just mentioned clearly indicate that members of the medical profession, who pay only one inclusive fee for life of £5 for technical admission to the Medical Register, should not be discontented with their position as compared with that of the legal profession, so far as the payment of fees and the control of the expenditure are concerned. According to my experience, an increase in the number of members of the Council, which is not a legislative, but a deliberative and administrative body, would only tend to embarrass and delay its proceedings. The members of the Council are elected and appointed under the most varied representative conditions, but they all tend to secure the high character and ability of its members, with a result which cannot be denied.

Before concluding these observations I am tempted to quote, from a recent address by the Lord Chief Justice of England on the subject of the improvement of legal education, an observation which has special reference to the work and constitution of our Council. His lordship says: 'Compare our legal system with the elaborate care and training in the medical and surgical schools. As has recently been well said by Sir Edwin Arnold, the labours of educational preparation for these professions grow, year by year, harder and harder—and so they ought. To be up to the high-water mark of proficiency, a young doctor must to-day be a chemist, physiologist, botanist, mechanician, and many things besides. Indeed, the history of medical education in recent years, from the time when the College of Physicians and the College of Surgeons commanded the principal avenues to the profession to the changes wrought by the legislation of 1858 and 1886, affords an instructive example of the improvements that may be effected under a body such as the General Medical Council, clothed with public responsibility, and broadly representative in its character.'"

On the motion of Mr. WHEELHOUSE, seconded by Sir WALTER FOSTER, the President was cordially thanked for his address.

Service Examinations.

Mr. W. J. C. MILLER, clerk to the Council, handed in tables showing the results of competitions: (*a*) for commissions in the Naval Medical Service, held on Nov. 4th, 1895; (*b*) for commissions in the Medical Staff of the army, held on Aug. 2nd, 1895; and (*c*) and (*d*) for commissions in the Indian Medical Service, held in February and August, 1895.

The Report of the Public Health Committee.

Dr. THORNE THORNE, Chairman of the Public Health Committee, called attention to the fact that the consideration of the report of the committee had been erased from the provisional programme of business, and moved that it be restored and the subject dealt with during the present session. It was certainly the case that there still remained two bodies to be visited and reported upon, but he did not think that a sufficient reason for further postponing this subject for six months. The committee thought it most desirable that the bodies should know at once what it was the Council desired in connexion with these examinations.

Sir WILLIAM TURNER said he was sure the Business Committee would be glad to listen to any suggestion Dr. Thorne Thorne had to make on this subject, and in these circumstances the formal motion was unnecessary.

Dr. THORNE THORNE pointed out that the subject had been deliberately struck out of the programme.

The PRESIDENT assured Dr. Thorne Thorne that there would be no difficulty in having it restored.

With this assurance Dr. Thorne Thorne withdrew his motion.

The Case of Mr. Thomas Richards.

The Council proceeded with the adjourned consideration of the case of Mr. Thomas Richards, registered as a Member of the Royal College of Surgeons in England, 1886, and Licentiate of the Royal College of Physicians of London, 1888, who at the November session last year was found to have committed the offence of covering an unqualified person at Llanhilleth, in the county of Monmouth. On that occasion the Council adjourned the further consideration of the case until the present session.

The PRESIDENT, in introducing the subject, said there was a general feeling in the Council last year that the punishment of removal from the Register would be too severe, and was not called for. Therefore, the further consideration of

Digitized by Google

the case had been postponed. Mr. Richards had not been called upon to attend, and it would not be necessary to move any resolution.

Dr. GLOVER thought the gentleman should now be informed by letter that the case was closed, and a notification to that effect should be placed upon the minutes.

Dr. MACALISTER agreed that something should be done, thinking it unfair to suspend anyone indefinitely.

Sir WALTER FOSTER moved a motion to the effect that the Council, having received satisfactory evidence that Mr. Richards had amended his conduct as required by the Council after his case was heard, resolve that his name be not removed from the Register.

This motion was at once accepted by the Council.

The Society of Apothecaries of London.

Mr. BRUDENELL CARTER read a letter from this society, dated July 11th, 1895, intimating that the society had determined to discontinue its examination in arts as from the end of the current year. He thought the Council would receive this notice with gratification, and he moved that the letter be received and entered on the minutes.

Dr. MACALISTER, seconding this motion, said he was sure the Council would desire to express their appreciation of the dignity and courtesy of the communication.

The motion was adopted by the Council.

Direct Representation.

Sir WALTER FOSTER moved:—

"That a committee be appointed to consider the resolution of the British Medical Association respecting the increase of the direct representation of the profession on the General Medical Council, and to report thereon to the Council at this session."

The resolution in question, which was passed at one of the general meetings of this Association in August last, was to the effect that the council of the Association should be instructed to take immediate steps to have a Bill introduced into Parliament providing that the registered medical practitioners in England and Wales be empowered to elect five additional direct representatives, the practitioners resident in Scotland one additional direct representative, and the practitioners resident in Ireland one additional direct representative to the General Medical Council. He thought it desirable that this resolution of the British Medical Association should receive some notice at the hands of the Council. As the matter stood at present the council of the British Medical Association was pledged more or less to proceed with this resolution and embody as much of it as was wise in a Bill to be placed before Parliament, and he should be sorry to see any conflict between this body and the British Medical Association in the arena of Parliament. He did not think it would be desirable in the interests of either party, and he hoped that the medical profession might attain what it desired without having to go through that very costly and tedious process. There was beyond all doubt a growing feeling among the medical profession that something should be done, not to convert this Council into a body entirely to protect medical interests, but rather to develop the body and give the general profession a little more confidence in it.

Mr. WHEELHOUSE, seconding the motion, said that when he was present at the meeting of the British Medical Association he saw how extremely strong the feeling was that the profession was not sufficiently represented in this Council. He did his best to explain what the feelings of this Council were on this point, but he was overborne. The opinion was so decided, that nothing would satisfy the meeting but that a strong resolution should be forwarded to this Council, and that this Council should be asked definitely to consider it. In these circumstances he thought the best course was to appoint a committee to go carefully and deliberately into the matter, and then to ask the Council to come to a definite conclusion.

Dr. MACALISTER opposed the motion. This, he said, was no communication to the Council; it was a threat, a pistol held at the head of the Council, and nothing could be more undignified than to proceed as was proposed. The answer of this Council could only be, "Let them go to Parliament."

Mr. BRUDENELL CARTER took the same line, saying that this Council owed no duties or responsibilities to the British Medical Association. His advice to the Council was just let them be doing, and he would vote against the proposed committee.

Dr. GLOVER said he was sorry to hear the last two speeches. The resolution of the Association was a most temperate one, and well worthy of consideration by this Council. Mr. Carter said that this Council owed nothing to the British Medical Association, that was an unfortunate statement.

Mr. BRUDENELL CARTER, interposing, said his statement was that this Council owed no responsibilities or duties.

Dr. GLOVER, accepting the correction, said that this could not be regarded as a satisfactory attitude for the Council to hold towards the British Medical Association, which included the majority of the medical profession. He thought that they had some responsibility to so large a body of the medical profession.

A vote was then taken, when 7 members voted for the motion and 21 members voted against it. The motion was accordingly rejected.

Instruction in Practical Midwifery.

Dr. GLOVER moved:

"That the Medical Council, having before it the petition of the British Medical Association at its late annual meeting on the inadequacy of the recommendation of the General Medical Council, in regard to instruction in practical midwifery, which petition is printed in the minutes of the Executive Committee, Nov. 25th, 1895, resolves that in the judgment of the Council no medical authority should require less from candidates for its qualification than attendance on thirty cases of labour, under the supervision of a registered medical practitioner; or three months' attendance on the practice of a lying-in hospital or maternity charity under the same supervision."

Dr. Glover also moved that the petition referred to be received and entered on the minutes. Its terms were:

"That we, the members of the British Medical Association, while anxious to improve the training and supervision, and if need be to support a practical scheme for the registration of medical, surgical, and midwifery nurses, emphatically condemn any proposal which has for its object the formation of a class of medical or surgical or midwifery practitioners other than those recognised under the Medical Act, 1886, as now existing.

"That we view with deep concern and regret the recommendation of the General Medical Council to the medical examining bodies that they should admit students to their final examination who present a certificate stating that they have 'conducted personally' only three, and 'been present at' only nine, confinements; and as the General Medical Council has refused in November, 1890, to alter this recommendation, we instruct our council to petition the General Medical Council to recommend that no student be admitted to his final examination until he presents a certificate showing that he has personally conducted at least thirty confinements under the direct supervision of a registered medical practitioner."

Dr. MACALISTER thought this communication should not be entered on the minutes. It seemed that the council of the British Medical Association had been instructed to petition this Council, but it had not taken the trouble to do so; it had merely sent on the resolution of the general meeting. Until this Council had a proper petition before them he did not think they could do anything.

Sir WALTER FOSTER confessed that there had been an omission somewhere with reference to the petition.

Dr. GLOVER differed from Dr. MacAlister in this matter. He respected the 15,000 members of the British Medical Association even more than he respected the thirty members who constituted the council of that body.

Dr. GAIRDNER said that while he respected the British Medical Association as a great association of practitioners, he differed entirely from the view that they should attach more importance to a vote taken at the general meeting than to a decision of the council arrived at after mature consideration. If the council had not prepared a petition he did not think they could proceed with the matter.

Dr. GLOVER said that he was anxious to present this subject without prejudice to the Council, but he could not consent to the withdrawal of his motion without a protest.

The motion was thereupon withdrawn.

Information for Local Registrars.

Dr. GLOVER asked whether the President had heard finally from the Registrar-General since his promise to consider the question of forwarding to the local registrars a notice of the erasure of any name from the Medical Register.

Mr. MILLER (the Registrar) said that a letter had been received from the Registrar-General stating that he would consider whether he would grant the Council's request that the list of erasures from the Medical Register be communicated from time to time to all registrars of births and deaths. That letter was dated June 21st. Another letter on the subject had been received from the Local Government Board. It had been written at the direction of Sir Walter Foster, then Parliamentary Secretary to the Board, and stated that if the annual cost of supplying the local registrars of births and deaths with the Medical Register would be £600, Sir Walter Foster was disposed to agree with the Secretary of the Treasury that the expense was excessive.

Digitized by Google

Sir WALTER FOSTER asked Mr. Miller if he had any estimate of the probable cost.

Mr. MILLER replied that he had made up a statement which showed that the number of local registrars was about 2500, and the cost of supplying them with the Medical Register would be about £250 and an additional £100 for postage.

Sir WALTER FOSTER said that when this subject was raised at a previous meeting he was a member of Her Majesty's Government, and he was very willing that the Council's suggestion should be given effect to. On putting the matter before Sir John Hibbert, that right hon. gentleman had expressed a very kindly feeling towards the proposal; but, some objection being afterwards taken on the score of expense, he had forwarded the letter from the Treasury to Mr. Miller to get the estimate of cost corrected. Then the Government, he thought, went out of office, and he had had no opportunity of receiving or sending the revised estimate to the Treasury. He thought the best thing the Council could now do would be to send a letter to the Treasury showing that the cost would be only about half the amount of their estimate.

Mr. TEALE thought it should be pointed out that the £100 for postage went to the Government, and that the actual outlay would be £250.

Dr. HERON WATSON said the county-court judges as well as the local registrars had been mentioned at the time the matter was discussed, and perhaps that accounted for the larger sum named by the Treasury.

Dr. GLOVER thought that after what had taken place they might now get a more satisfactory reply from the Registrar-General.

In the course of further discussion it was suggested that a cheaper and perhaps the better, way of obtaining the object in view would be to print for distribution lists of the names of persons erased from the Register. Ultimately, on the motion of Dr. GLOVER, seconded by Sir WALTER FOSTER, it was resolved unanimously that the President be requested to communicate further with the Registrar-General with the view of ensuring that local registrars should be informed of the erasures of any names from the Medical Register.

Disciplinary Functions of Qualifying Medical Authorities.

The next business on the paper was the following notice of motion in the name of Dr. Glover, viz.:

"That it be an instruction to the Executive Committee to revert to the consideration of the subject of the disciplinary functions of the qualifying medical authorities and of the General Medical Council, and to report to the Council at its next meeting on the best means of further defining and confirming these functions and bringing them into harmonious and efficient coöperation."

Dr. GLOVER asked that this proposal should stand over till Wednesday. He had been speaking a good deal already, and he respectfully submitted that it would be better for the Council to proceed with a notice standing in the name of Dr. Heron Watson.

Sir WILLIAM TURNER pointed out that the motion just referred to was not quite ready for discussion. He suggested that Dr. Glover should go on.

Dr. GLOVER said he felt his case was a very hard one, but he hoped the Council would feel all the more disposed because of that to accept his proposal. The subject dealt with in his resolution was an old one. It had been very fully dealt with by their late President, Mr. Marshall, and if they would turn to vol. xxv. of their Minutes they would see that it contained documents on the disciplinary powers of not only the qualifying authorities, but also of the General Medical Council. The general result of Mr. Marshall's inquiry was to show that more or less these qualifying bodies had disciplinary powers, and particularly the supreme power of taking away the diplomas they had given. Some of them also possessed the power of restoring them after they had been taken away, but that power was not so general as was the power to withdraw them. On the result of the inquiry coming before the Council, the subject was referred to the Executive Committee, and the volume of the Minutes for 1889 (vol. xxvi.) contained the resolution of the Executive Committee, which was to the effect that the Council's legal advisers should be advised to frame certain resolutions with the view of facilitating procedure in penal cases. That was the last thing done; the matter ended with the suggestion of a committee for penal cases. If they looked at the expenditure of time and money on penal cases dealt with since that committee was suggested, they would feel convinced that it had not brought into harmony the procedure of the qualifying bodies, and that there now existed the same want of harmony that existed at the time of Mr. Marshall's inquiry. In his opinion the time had therefore come for the further consideration of the subject with the view of securing some uniform powers on which the several bodies might act. The penal committee had not made any difference in the amount of the disorder, or the amount of reliance the Council could place on the individual bodies. There still was the same want of harmony, certainty, and uniformity in the individual bodies. Some of these bodies did not have disciplinary powers. For instance, the Apothecaries' Society at Blackfriars did not have it, but had expressed a willingness to possess it. Most of such bodies as had the power of withdrawing names did not possess the power of restoring them. In their new by-laws the Royal College of Surgeons of England included not only the power of removing but also of restoring names. If the disciplinary power was inherent in these bodies, that should be made clear. Its existence had been recognised by the Medical Act, and if it was made clear that all bodies had the power of withdrawing and also of restoring names he firmly believed that the mischief of which they now complained would be corrected at its beginning.

Dr. THORNE THORNE, in seconding the motion, said that he had endeavoured to make himself acquainted with the powers and duties of the Council, and if there was one impression made upon him deeper than another it was that the penal powers the Council exercised were about the most unsatisfactory. He had seen them spending two or three days in investigating the conduct of a medical man whom everybody had felt deserving of punishment for doing wrong, but who had escaped because his conduct did not happen to be the infamous conduct in a professional respect that the Council could deal with. It seemed to him that it would tend very greatly to raise the tone of the profession if the several bodies were able to call up people and warn them at an early stage of offensive conduct rather than when it had become more mature. A small body could deal with offenders judicially and warn them, but in this General Medical Council it took some days for a body of thirty men to come to no conclusion whatever. He himself did not feel competent to discuss this question fully, but he had great pleasure in seconding the motion in order that it might be fully discussed.

Mr. BRYANT thought the qualifying bodies should have a certain control over their own Licentiates, but anyone who would read Mr. Marshall's report must feel how utterly hopeless it was to get the universities and other bodies to look at it in that light. He had gone over the report in a careful way not long ago, and he thought some of these bodies might be willing to accept help from this Council in defining what their position was. If an Act could be obtained which would give, if not all that was wanted, at any rate the power to remove names, it would be a great step in the right direction.

Mr. TEALE said they were hampered by the fact that when they took a name off the Register there were certain bodies that could not restore it. That, he thought, was the great difficulty. At the same time they could not expect the universities, which dealt with many sorts of degrees, to have special privileges for any one class of their graduates. But universities had not the machinery to go into matters of this kind. Still, if it were possible to get a general Act which empowered the universities to remove names taken off the Register by the General Medical Council, he thought they would not refuse to exercise that power.

Sir WILLIAM TURNER said that on the last occasion Dr. Glover brought this matter before the Council he asked him (Sir William Turner) if he could say what the Scotch universities would be likely to do. He had in reply told the Council that he would bring the matter before the Commission which was then sitting. He had remembered that promise, and he thought he might say that with Dr. Heron Watson's assistance the whole case was fully stated to the Scottish Universities Commissioners. What resolution these gentlemen might come to he could not say. He suggested that Mr. Miller might see if there were left any copies of the Bill on the subject drafted during the former inquiry, and if there were that these should be distributed among the members of the Council.

Dr. LEECH thought that all universities might so act as to get the power to remove names.

Sir JOHN BANKS had great pleasure in supporting the motion. The two universities of Ireland, he said, were most anxious to have the power to remove black sheep.

Digitized by Google

Dr. HERON WATSON remarked that the Royal College of Surgeons of Edinburgh were most anxious to carry out this disciplinary power, and they were advised that they had it already and might exercise it in regard to the Fellows. Still, the difficulty was to get agreement amongst the bodies, and the matter altogether was one that required very careful consideration before any action was taken.

Mr. BRUDENELL CARTER said that although they all sympathised with the object, yet the executive would have many difficulties to consider and clear away. He hoped that if the executive took the matter in hand they would devote to it sufficient time to look at it from all points of view.

Sir WALTER FOSTER hoped the resolution would be carried. When Mr. Marshall started the inquiry the hope was that the Council might get the qualifying bodies to do many of the duties that fell on this Council. He (Sir Walter Foster) did not see any chance of transferring to those bodies the discipline of the profession, but the motion was an inarticulate cry for more discipline and more means for discipline.

Dr. GAIRDNER was thoroughly in sympathy with Dr. Glover's object. Whatever could be done in this direction should be done. As had been pointed out, the difficulty in regard to the universities was really the deficiency of machinery.

Sir WILLIAM TURNER suggested that they might now take the vote, and perhaps Dr. Glover's motion was as wise as any other.

The motion was unanimously adopted.

The Case of Mr. R. M. Theobald.

The Council proceeded to discuss in private the application of Robert Masters Theobald for a rehearing of his case. On the public being readmitted,

The PRESIDENT informed the applicant that the attention of the Council had been very carefully directed to his case, and the result of their deliberation would be announced by Mr. Muir Mackenzie.

Mr. MUIR MACKENZIE said that the first head of the application was that the former proceedings in the case should be declared null and void. The Council had declined to do that. The second head of the application was that the applicant's name should be restored to the Register. The Council declined to make any order.

Mr. THEOBALD asked if there was any avenue by which he might take further action.

Mr. MUIR MACKENZIE said he could comply with the standing orders.

Mr. THEOBALD said that he had already made application under the standing orders. He had fulfilled all the conditions under the standing orders. Why could he not be restored?

Mr. MUIR MACKENZIE: The matter has been considered and decided upon.

Mr. THEOBALD: I ask, Why?

Mr. MUIR MACKENZIE said that it was a condition precedent to applicants obtaining restoration under the standing orders that he should obtain restoration under the Act, that he should be in possession of a qualification or diploma, and he was not in possession of any diploma entitling him to restoration.

Mr. THEOBALD believed the Council had the power of restoring his qualification whether he had a diploma or not. He asked whether it was a condition precedent that he should obtain restoration from the Royal College of Surgeons.

Mr. MUIR MACKENZIE: Yes.

Mr. THEOBALD then asked that the Council should give him a certificate to fortify him in his application to the Royal College of Surgeons.

The PRESIDENT: Mr. Muir Mackenzie says this case is at an end. It would not be in the power of this Council to make any recommendation.

Mr. THEOBALD: I am very sorry. I think you are entirely wrong.

The PRESIDENT: We are advised that it is not so.

The Council adjourned.

WEDNESDAY, NOV. 27TH.

The Council met again to-day, Sir RICHARD QUAIN presiding. In revising the minutes of the previous sitting the Council decided to insert that Dr. Glover withdrew his motion on the ground that the petition of the British Medical Association had not reached the Council.

The Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries' Hall of Dublin.

Mr. WHEELHOUSE asked leave to make a correction in the speech he delivered during the debate last June on the examinations of the Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries' Hall of Dublin. In moving the adoption of the report on this occasion he said that he had visited the last two examinations of the board, and had found that great improvements had been made, and that he and Dr. Duffey were tolerably satisfied except with regard to the examination in medicine. He went on to say that the candidate to whom they took exception, although well versed in theory, knew nothing about practice, and then, unfortunately, he added the words that he had now passed as a qualified man. It had since been brought to his notice that this was entirely incorrect, and that the gentleman was not passed as qualified—that he was not a qualified man at this moment. Though he had passed through medicine, as they described in their report, he had previously been stopped in pathology and also in surgery. It had been said that this statement of his prejudiced the Council against the Board and also the Privy Council. He did not think it could be so. He imagined that the Privy Council had had the report before it and had discussed it purely on its merits, as this Council had done. But what he desired to do was to apologise to the Conjoint Board for the mistake he had made.

The PRESIDENT suggested that there should be some reference to this matter in the minutes.

Sir PHILIP SMYLY (who represents on the Council the Royal College of Surgeons of Ireland) asked to be allowed to make a statement at this point.

Sir WILLIAM TURNER thought that a discussion now would be extremely irregular.

Sir DYCE DUCKWORTH (chairman of the Examination Committee) said that little slips of this kind had happened before, and it could not be pretended that this single statement had materially influenced the decision of the Council.

Sir PHILIP SMYLY submitted that this supposed passing of this man was the only point upon which the examination was considered insufficient.

Sir DYCE DUCKWORTH said it was absolutely grotesque to suppose that the Council made its representation to the Privy Council on the strength of this little *lapsus*.

The PRESIDENT pointed out that there had been four special inspections of the examination and that the condemnation was general.

The Council then proceeded to consider the position with regard to the Conjoint Board.

The PRESIDENT suggested that the Board should continue to exist as before until a fitting opportunity had been given to the remaining candidates to come forward for examination.

Sir PHILIP SMYLY said he did not think his College would recombine with the Apothecaries' Hall except for this special purpose. The report to the Privy Council had nothing whatever to do with their separating from the Apothecaries' Hall. They had given their notice to separate considerably before there was any report to the Privy Council, and the two things were perfectly distinct.

The Clerk then read the following two letters received from the Privy Council, viz.:

"Privy Council Office, Whitehall,
"August 10th, 1895.

"SIR,—Referring to your letter of the 13th June last containing a copy of a Resolution of the General Medical Council to the effect that the standard of proficiency in Medicine required from candidates at the Qualifying Examinations held by the Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries' Hall of Dublin is insufficient, and enclosing a copy of Reports of the Council's Inspector and Visitor on the subject, I am directed by the Lord President of the Council to transmit to you the accompanying copies of replies to the same which have been received from the Council of the Royal College of Surgeons in Ireland and the Governor and Council of the Apothecaries' Hall, Dublin, respectively. I am directed by the Lord President to state, for the information of the General Medical Council, that it appears to be unnecessary for the Privy Council to come to any decision as to the insufficiency or otherwise of the examinations in question under Section 4 of the Medical Act, 1886, inasmuch as it appears from the documentary evidence before His Grace that the Conjoint Board is no longer in existence.

"I am, Sir, your obedient servant,
"C. L. PEEL.

"To Sir Richard Quain, Bart., M.D.,
"President of the General Medical Council."

"Privy Council Office, Whitehall.
"October, 1895.

"SIR,—Referring to my letter of the 10th August last, stating that it appeared to the Lord President of the Council unnecessary for the Privy Council to come to any decision as to the insufficiency or otherwise of

the Examinations of the Conjoint Board of the Royal College of Surgeons in Ireland and the Apothecaries' Hall, Dublin, inasmuch as from the documentary evidence before His Grace (see paragraph 2 of letter from Royal College of Surgeons in Ireland of the 27th July, 1895), it appeared that the Conjoint Board was no longer in existence, I am directed by the Lord President to state for the information of the General Medical Council that a letter (16th October, 1895), copy of which is enclosed, has been received from the Secretary of the Council of the Royal College of Surgeons in Ireland, from which it will be seen that although, as he states, the scheme has ceased for new entries, the Conjoint Board will continue for some time to come to carry on examinations. Under these circumstances the Lord President will be glad to be informed how long these Conjoint Examinations are likely to be continued, and also whether the General Medical Council have any observations to offer on the explanations submitted to His Grace by the Royal College of Surgeons and the Apothecaries' Hall, Dublin, which were forwarded to you with my letter of the 10th August last. I have the honour to be, Sir, your obedient servant,

"Sir Richard Quain, Bart., M.D., C. L. PEEL.
"President of the General Medical Council."

The Clerk also read a letter from Mr. Robert H. Woods, Secretary of the Council of the Royal College of Surgeons of Ireland, containing the following passage:—

"The Conjoint Committee, to whom the matter has been referred by the Council of the Royal College of Surgeons, report that the total number of candidates who have entered under the scheme since its inception is 159; that of these 97 have passed the Final Examination, and the remainder, 62, have not yet completed their course. This latter number includes four qualified practitioners who were rejected at the Final, two candidates who, having been rejected, entered and passed under other qualifying examinations and are now on your Register, and an unknown and unknowable number of other candidates who have given up medicine as a profession, or entered under other schemes.

"It will be necessary to continue the examinations as long as any of these candidates present themselves."

Sir WILLIAM TURNER suggested that the Council should now consider the question how long these conjoint examinations were likely to be continued.

Mr. BRUDENELL CARTER put forward the idea that there might be a limit of time.

Sir PHILIP SMYLY explained that in the precedent of the Royal Universities in Ireland there was no limit of time and the two systems were carried on alongside. At the same time he thought five or six years would suffice for all practical purposes.

Dr. MCVAIL said that in the case of the Scottish Universities there was no time limit. In Glasgow five years ago a degree had to be given under the regulations which were in force before 1858.

Sir PHILIP SMYLY thought that if there was a time limit it should be made by this Council and not by the bodies.

Dr. MACALISTER, seconded by Sir WILLIAM TURNER, moved a resolution to the effect that the Conjoint Board be requested to furnish the Council with a list of the names and dates of admission of the candidates who have already passed some of the examinations, but who had not at July 1st, 1895, completed the series of examinations for the Board's qualifications.

This was at once agreed to, as was also a resolution to the effect that the President be requested to inform the Lord President of the Privy Council that the Council were legally advised that the Conjoint Board has not ceased to exist, so far as regards students who have entered for the examination of the Board before July 1st, 1895; that it appeared to the Council that all existing claims for admission to the examination should be exhausted within six years from the present date; and that the Council understood that the two bodies constituting the Conjoint Board were prepared to carry out the arrangements necessary for meeting these claims to examination, of which there were probably about sixty.

The CLERK, at the request of Sir WILLIAM TURNER, read the following condensed statement prepared by Mr. Woods of the Royal College of Surgeons of Ireland, viz.:

"The Council confidently hopes that it has not merited this condemnation for these reasons:—

"1st. That the report has not been seen by the Council at all when the Medical Council passed judgment.

"2nd. That the Council of the College was entitled to have time for the consideration of the report and the preparation of a reply, and that no time was given for these purposes.

"3rd. That the report on the subject of medicine is based upon a difference of opinion between the Examiners and the Visitor and the Inspector, and the Council points out that the Examiners were entirely competent and experienced.

"4th. That the judgment of the General Medical Council was influenced by emphatic statements which have been shown to be absolutely without foundation.

"5th. That the union known as the Conjoint Scheme of the Royal College of Surgeons in Ireland and the Apothecaries' Hall, Ireland, has ceased to exist, and that when the General Medical Council reported the examination to the Lords of the Privy Council as insufficient, it knew that the scheme was within a few days of terminating."

He also read the following statement by Mr. Charles R. C. Tichborne, Governor of the Apothecaries' Hall of Dublin, viz.:

"The Hall therefore submit:—

"(1) That any imperfection in the conduct of the examinations has been due to causes which can be remedied and to difficulties which can be overcome.

"(2) That their undertaking to maintain a sufficient standard of medical examination should be accepted, and assistant surgical examiners be appointed by the Medical Council.

"(3) That nothing has been done by the Hall meriting disfranchisement. In several respects the examinations have been commended, and the only point of unfavourable comment in the last report of the visitor and inspector has arisen from what seems to be an error.

"If there is anything in the case on behalf of the Apothecaries' Hall as embodied in this letter, and the accompanying Appendices 1 and 2, which does not clearly afford a complete answer to the representation made by the General Medical Council to the Privy Council, the Hall would ask your Grace's permission to be heard by counsel on their behalf before the Privy Council."

Sir PHILIP SMYLY said that the Royal College of Surgeons of Ireland had always supplied good and efficient examiners, and in the last two reports the examination in medicine was declared satisfactory and only insufficient upon the question of marking.

Sir DYCE DUCKWORTH pointed out that the two bodies combined for this examination, and there could be no division of responsibility in the matter.

Dr. MACALISTER moved a resolution in effect that the President of this Council be requested to inform the Lord President of the Privy Council that the opinion of this Council as to the standard of proficiency in medicine required by the Conjoint Board was based on the results, not of one inspection only, but of four special inspections and visitations, and that the remarks made in the communications of the bodies had been considered by the Council, and the Council saw in them no reason for altering their opinion as to the standard in question.

Dr. CHARLES MOORE, the representative of the Apothecaries' Hall of Dublin, addressed the Council at some length. The Hall, he said, had suffered peculiar difficulties in obtaining examiners in medicine owing to the opposition of the Royal College of Physicians of Ireland. If a man attempted to examine for them he had no prospect of promotion from the Royal College of Physicians. He was prepared to prove that.

Dr. ATTHILL: Will you give the name?

Dr. MOORE: I will not give any name.

Dr. ATTHILL: Then I say it is not a true statement.

Dr. MOORE concluded by moving an amendment: "That the printed reports of the General Medical Council do not justify a condemnation of the conjoint bodies of Surgeons and Apothecaries, inasmuch as several other bodies have been pronounced insufficient in most important particulars, but have not been condemned."

Sir PHILIP SMYLY undertook to second this amendment.

The amendment, however, received no other support than the votes of its mover and seconder, and the motion proposed by Dr. MacAlister was carried.

It was also agreed that the Lord President be further informed that if and so long as the Conjoint Board's examinations continue to be deemed by the Privy Council to be qualifying examinations under the Medical Act the General Medical Council is unable to secure the maintenance of the standard of efficiency otherwise than by continuing inspection and visitation.

Dr. HERON WATSON moved that these findings of the Council be conveyed to the Lord President by deputation.

Sir DYCE DUCKWORTH seconded the proposal.

On a division only four voted for the motion, which was accordingly lost.

Application for Appointment of Examiners.

The next business on the paper was consideration of the following application from the Apothecaries' Hall of Dublin for the appointment of assistant examiners in surgery:—

"Dublin, November 21st, 1895.

"DEAR SIR,—I am directed by the Governor and Court of Apothecaries' Hall, Ireland, to petition the Council to appoint two Examiners in Surgery, under the provision of the Medical Act, 1886, as their conjunction with the Royal College of Surgeons, Ireland, has ceased in July, 1895. If permission is granted, the Court herewith submit two names for the approval of the Council, or will receive two names from the Council if so directed. I am requested to ask you to place the above before the Council at ensuing meeting.

"The Governor and Court beg to submit to the General Council the following names as suitable Examiners in Surgery, and they have intimated their willingness to act.

"Francis T. Heuston, M.D. R.U.I., F.R.C.S., and M.C.R.C.S., Surgeon to the Adelaide Hospital.

"F. Conway Dwyer, M.B., Bac. Surg. T.C.D., Surgeon to Jervis-street Hospital.

"Faithfully yours,
"ROBERT MONTGOMERY, M.R.C.S., Secretary.

"To Sir Richard Quain, M.D., Bart.,
"President of the General Council."

Digitized by Google

Dr. BATTY TUKE asked whether the body making this application had fulfilled all the conditions laid down in Section 5 of the Medical Act of 1886. There was no evidence on the face of the letter that they had exhausted all the means in their power to obtain examiners in Ireland.

Dr. MACALISTER wished to say further that, as the Council had agreed that the Conjoint Board was not extinct, it was impossible for them to appoint examiners for the Apothecaries' Hall separately. They were barred by the statute from making any appointment.

Dr. GLOVER said he should like to hear the lawyers before accepting Dr. MacAlister's dictum. He moved that they proceed no further with the application until they obtained the opinion of their legal advisers on the subject.

Sir PHILIP SMYLY seconded this motion.

Sir WILLIAM TURNER said it would be very satisfactory if Dr. Charles Moore could tell the Council whether the Apothecaries' Hall had exhausted all the means of forming a combination with the Irish Universities and corporations.

Dr. CHARLES MOORE replied in the affirmative. When combination with the College of Physicians was suggested, it was pointed out to them that combination of the Apothecaries' Society with that College would be like a case of a lady marrying a lady. The University of Dublin had replied to their letter that they did not see their way to unite with the Apothecaries' Hall, and the Royal University of Ireland had sent them the same answer. These replies had been received within the last few weeks.

Sir WILLIAM TURNER said that in that case the Council ought to have from the Secretary of the Apothecaries' Hall a distinct statement in writing. Without such a statement they could not determine whether there had been compliance with the Act

Dr. MCVAIL thought the Council should accept the specific statement of the accredited representative of the Apothecaries' Hall.

The PRESIDENT reminded Sir William Turner that the Council were constantly accepting assurances from its own members.

Dr. HERON WATSON's view was that the answers made to the Apothecaries' Hall should come from the representatives of the Irish Universities rather than from the representative of the Hall. If they had no information from these representatives they ought to have documentary evidence that the Apothecaries' Hall had made this application, and that the Universities had answered it.

Dr. BRUCE said that no such written evidence as was wanted here was required some years ago in the case of the London Apothecaries' Society's similar application.

Mr. CARTER looked upon it as a new and startling opinion that the assurance of one of their members was to be taken as of less importance than the statement of the secretary of the body he represented. Those who had raised the question had, no doubt quite unintentionally, cast a slur on the dignity of the General Medical Council. He, for one, was perfectly satisfied with the statement made by his colleague on the Council.

Dr. LOMBE ATTHILL said Dr. Charles Moore's statement was quite sufficient for him.

Dr. MCVAIL directed attention to the opinion of counsel as before them during the previous subject of consideration. He pointed out that Mr. Muir Mackenzie laid it down that the General Medical Council "could not, as long as the two corporations agree to continue examinations for the existing students in combination, refer any such student to a board consisting of the Apothecaries' Hall assisted by examiners in surgery appointed by the General Medical Council. The power to appoint assistant examiners only arises where a corporation represents that it is unable to combine, and here the Hall is not unable to enter into the combination so far as the existing students are concerned." He (Dr. McVail) did not think that opinion blocked the way of the Council in the appointment of examiners, but in view of the opinion that candidates who entered after July last "would have to be examined by a board formed by the Hall, with examiners nominated by the General Medical Council under Section 5 of the Act," he thought there was force in the view expressed by Dr. MacAlister.

Dr. MACALISTER would like to have advice as to whether they could go on under Section 5. He proposed that Mr. Muir Mackenzie should be asked to advise the Council whether, under Section 5 of the Act of 1886 or other legal provision, the Council had power to appoint additional examiners in surgery in respect of students entering after July 1st, 1895.

Dr. GLOVER, withdrawing his own proposal, seconded the motion, which, after some remarks by Sir P. SMYLY and WALTER FOSTER, was unanimously carried.

Sir WILLIAM TURNER thereupon remarked that the Council could not now come to a decision that [illegible] ventured to ask Dr. Charles Moore to write to Dublin [illegible] letters of the two universities definitely refusing to [illegible] with the Apothecaries' Hall. It was important the [illegible] should have these documents before them, because [illegible] step they took in this case would be carefully watched [illegible] they must therefore be wary in their procedure.

Dr. CHARLES MOORE, remarking that it had been [illegible] intention of the secretary to send the documents to [illegible] agreed to write for them.

Further consideration of the matter was then [illegible] to Friday.

The Medical Register.

Dr. HERON WATSON directed attention to certain [illegible] of the Medical Act relating to registration. He said [illegible] provisions implied that there were no less than five [illegible] required. There was the General Register, which [illegible] of some thirty volumes, and was kept in the office [illegible] Council; then there were three branch registers, [illegible] for England, Scotland, and Ireland; and then there [illegible] printed copy of the General Medical Register, which [illegible] issued on Jan. 1st in each year. Of these [illegible] only that in the hands of the Council's Registrar [illegible] to be complete. The Medical Register could [illegible] correct at the time it went to press, and as the year [illegible] it must become more and more inaccurate. The [illegible] changes made in 1894 were 11,000, or upwards of [illegible] every month. That showed that very little [illegible] could be placed on the Register as the year drew [illegible] end, and much inconvenience must be felt in Scotland [illegible] Ireland when there was any inquiry as to a newcomer [illegible] district or a practitioner who was not well known. The [illegible] increased by the fact that the changes made in the [illegible] Register were not communicated to the branch registrars [illegible] for England and Scotland. These registrars were [illegible] to send to the Council's Registrar twice a month a list [illegible] changes made in their local registers, and he thought [illegible] should be reciprocity and that these registrars should [illegible] informed once a fortnight of the changes made in the [illegible] General Register, so that the Scottish and Irish registers [illegible] should be kept in touch with the changes made in the [illegible] Register fortnight by fortnight. He therefore moved "That [illegible] the Council direct that the changes made by the Registrar in [illegible] the General Register, whether as respects the addition [illegible] moval of names, or the alteration of names or of residences [illegible] be communicated twice in every month to the [illegible] registrars in Scotland and in Ireland, and that a like [illegible] munication of alterations in Scottish and Irish registers [illegible] communicated to the Scottish and Irish branch registrars [illegible] respectively, with a view to such alterations being entered [illegible] them in an interleaved copy of the printed Medical Register [illegible] supplied to the branch registrars when such issue of the [illegible] Register is annually made."

Sir WILLIAM TURNER seconded the motion.

The REGISTRAR (Mr. Miller) expressed the opinion that [illegible] the proposal could be given effect to, and whatever the [illegible] Council ordered should be done.

The motion was unanimously agreed to.

The Council, after sitting for a few minutes in private, [illegible] adjourned.

THURSDAY, NOV. 28TH.

The Council met and dealt with the case of Mr. Geo. [illegible] Francis McCarthy (registered as Lic. Midwif. [illegible] K.Q. Coll. Phys. Irel.; Mem. R. Coll. Surg. Eng. [illegible] who at the June meeting was found to have committed [illegible] the offence of covering an unqualified person in a practice [illegible] South London. Mr. McCarthy attended, and the President [illegible] addressed to him a number of questions as to the manner [illegible] which he has been employed since June. He gave the [illegible] Council an emphatic assurance that he would never [illegible] employ in his practice an unqualified assistant. The decision [illegible] of the Council was not to withdraw Mr. McCarthy's name [illegible] from the Medical Register.

Thereafter the Council proceeded in committee to consider [illegible] and discuss the specific recommendations made by the [illegible] Examination Committee in regard to the results of various [illegible]

Digitized by Google

and inspection of the final examinations in medicine, surgery, and midwifery of all the licensing bodies. Our issue next week will contain a report of what was done.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Members of the College:—

Abbott, James Edward, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Ash, Percy Roberts, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Ashwin, Richard Hamilton, L.R.C.P. Lond., Guy's Hospital.
Aubin, Emile Dupont, L.R.C.P. Lond., Middlesex Hospital.
Barron, Thomas Ashby, L.R.C.P. Lond., Bt. Bartholomew's Hospital.
Beadles, Arthur Harry, L.R.C.P. Lond., St. Bartholomew's Hospital.
Belcher, George Clement, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham.
Bell, Thomas Dobson, L.R.C.P. Lond., University College and Hospital.
Bernstein, Matthias Max, L.R.C.P. Lond., University of Moscow.
Bodman, John Hervey, L.R.C.P. Lond., St. Bartholomew's Hospital.
Bostock, Eustace Bernard, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham.
Bowes, Tom Armstrong, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Boyton, Arthur James Henry, L.R.C.P. Lond., St. Bartholomew's Hospital.
Breton, Lancelot Moyle, L.R.C.P. Lond., St. Thomas's Hospital.
Bradley, William Inglis, M.D. McGill, McGill College, Montreal.
Brown, Ralph Charles, L.R.C.P. Lond., Melbourne University and Westminster Hospital.
Bull, Harry Ashworth, L.R.C.P. Lond., St. Thomas's Hospital.
Caglieri, Guido Enrico, L.R.C.P. Lond., St. Ignatius College and California University, and Genoa University.
Campbell, Archibald John, L.R.C.P. Lond., St. Thomas's Hospital.
Cant, Arthur, L.R.C.P. Lond., Mason College, Queen's and General Hospital, Birmingham.
Carden, William Alfred, L.R.C.P. Lond., Guy's Hospital.
Cawley, George, L.R.C.P. Lond., St. Bartholomew's Hospital.
Child, Gerald Alfred, L.R.C.P. Lond., Oxford University and St. Thomas's Hospital.
Clark, Richard Foster, L.R.C.P. Lond., Guy's Hospital.
Connell, Arthur Mayers, L.R.C.P. Lond., University College and Hospital.
Cooke, Arthur, L.R.C.P. Lond., Oxford University and London Hospital.
Cooke, Martin Alfred, L.R.C.P. Lond., St. Bartholomew's Hospital.
Coutts, Francis James, L.R.C.P. Lond., University College and Hospital.
Cox, Henry Procter, L.R.C.P. Lond., King's College and Hospital.
Creasy, Laurence Eliot, L.R.C.P. Lond., University College and Hospital.
Crosby, Arthur Henry Pascal, L.R.C.P. Lond., Middlesex Hospital.
Crossley, Samuel, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Dempsey, Patrick Joseph, L.R.C.P. Lond., Master Misericordiæ Hospital and Catholic University, Dublin.
Dhingra, Behari Lal, L.R.C.P. Lond., University College and Hospital.
Dudley, Arthur Dudley Parr, L.R.C.P. Lond., University College and Hospital
Dun, Robert Craig, L.R.C.P. Lond., Edinburgh and Berne Universities.
Dyball, Brennan, L.R.C.P. Lond., St. Thomas's Hospital.
Eames, Charles William, L.R.C.P. Lond., Edinburgh University, Yorkshire College, and General Infirmary, Leeds.
Evans, Evan Laming, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Fairbairn, John Shields, L.R.C.P. Lond., Oxford University and St. Thomas's Hospital.
Farmer, William Henry, L.R.C.P. Lond., St. Bartholomew's Hospital.
Fincham, Ernest Charles, L.R.C.P. Lond., St. Bartholomew's Hospital.
Fleming, Wilfrid Louis Remi, L.R.C.P. Lond., Westminster Hospital.
Fletcher, Roland Henry, L.R.C.P. Lond., University College and Hospital.
Flower, Arthur Frederick Ashbrook, L.R.C.P. Lond., St. Bartholomew's Hospital.
Frazer, William Dyer, L.R.C.P. Lond., St. Thomas's Hospital.
Ganner, Joseph, L.R.C.P. Lond., Mason College, Queen's and Gener Hospitals, Birmingham.
Genge, George Frederick Saunders, L.R.C.P. Lond., Westminster Hospital.
Giblin, Wilfred Wanostrocht, L.R.C.P. Lond., St. Bartholomew's Hospital.
Gilmour, Richard Withers, L.R.C.P. Lond., St. Bartholomew's Hospital.
Gross, Charles Frederick, L.R.C.P. Lond., King's College and Hospital.
Hardcastle, William, L.R.C.P. Lond., Charing-cross Hospital.
Hardy, Frank Samuel, L.R.C.P. Lond., Firth College, Sheffield, and University College and Hospital.
Harris, Norman MacLeod, L.R.C.P. Lond., General Hospital and University, Toronto.
Hartley, Thomas Sidney, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Hay, John, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
Hayden, George Alfred Thomas, L.R.C.P. Lond., London Hospital.
Hearnden, Hamilton, L.R.C.P. Lond., Guy's Hospital.
Heptinstall, Robert Hollings, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Hewetson, Henry, L.R.C.P. Lond., Guy's Hospital.
Hill, Ernest Gardiner, L.R.C.P. Lond., St. Mary's Hospital.
Holme, Crampton Whitaker, L.R.C.P. Lond., Edinburgh University.
Hora, Julian, L.R.C.P. Lond., Guy's Hospital.
Hubert, William Arthur, L.R.C.P. Lond., St. George's Hospital.
Huckle, Arthur Henry Headley, L.R.C.P. Lond., Guy's Hospital.
Hughes, Leonard Sonstadt, L.R.C.P. Lond., University College and Hospital.
Humphris, Francis Howard, L.R.C.P. Lond., Edinburgh University and University College and Hospital.
Jones, Edward Francis, L.R.C.P. Lond., London Hospital.
Joyce, Robert Dwyer, L.R.C.P. Lond., Mater Misericordiæ Hospital and Catholic University, Dublin.
Kent, Percy Wheeler, L.R.C.P. Lond., St. Thomas's Hospital.
Lambe, Thomas, L.R.C.P. Lond., University College and Hospital.
Lelean, Percy Samuel, L.R.C.P. Lond., St. Mary's Hospital.
Leon, John Temple, L.R.C.P. Lond., St. Mary's Hospital.
Lermitte, Edward Augustus, L.R.C.P. Lond., Durham University and St. Bartholomew's Hospital.
Lincoln, Charles Hope Septimus, L.R.C.P. Lond., Madras Medical College and Guy's Hospital.
Loud, Frank, L.R.C.P. Lond., Guy's Hospital.
Lydall, Wykeham Tracy, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
Mackenzie, Alexander, L.R.C.P. Lond., Cambridge University, Yorkshire College, and General Infirmary, Leeds.
Macmillan, Niel Harrismith, L.R.C.P. Lond., Edinburgh University.
Madden, Francis Brian, L.R.C.P. Lond., St. Bartholomew's Hospital.
Manby, Walter Edward, L.R.C.P. Lond., Cambridge University and King's College Hospital.
Marshall, Gerald Seymour Sankey, L.R.C.P. Lond., Middlesex Hospital.
Martineau, Alfred John, L.R.C.P. Lond., St. Thomas's Hospital.
Mayne, Bertie James, L.R.C.P. Lond., Middlesex Hospital.
Miller, George, L.R.C.P. Lond., St. Bartholomew's Hospital.
Muggleton, Ferdinand Charles Harry, L.R.C.P. Lond., London Hospital.
Murray, John Hanna, L.R.C.P. Lond., University College and Hospital.
Myrtle, George Yule, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds, and St. Mary's Hospital.
Nott, Herbert Walter, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
Nuthall, Alex Wathen, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham.
Ormerod, Ernest William, L.R.C.P. Lond., University College and General Hospital, Bristol.
O'Sullivan, Daniel, L.R.C.P. Lond., London Hospital.
Pearse, Joseph Steele, L.R.C.P. Lond., Middlesex Hospital.
Penny, William Reginald, L.R.C.P. Lond., Westminster Hospital.
Pepper, Henry William, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham.
Perkins, George, L.R.C.P. Lond., Madras Medical College and University College Hospital.
Perry, Walter Dymock, L.R.C.P. Lond., Middlesex Hospital.
Pritchard, Harry Washington, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Ransome, Arthur Cyril, L.R.C.P. Lond., Cambridge University and St. Mary's Hospital.
Rawson, William Foster, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Rees, David Charles, L.R.C.P. Lond., Charing-cross Hospital.
Roger, Arthur Anderson, L.R.C.P. Lond., St. Bartholomew's Hospital.
Rundle, Claude, L.R.C.P. Lond., St. Mary's Hospital.
Savin, Lewis, L.R.C.P. Lond., Middlesex Hospital.
Sears, Alfred Ernest, L.R.C.P. Lond., London Hospital.
Shelley, Percy Wilfred Graham, L.R.C.P. Lond., St. Bartholomew's Hospital.
Shepheard, Henry, L.R.C.P. Lond., St. Thomas's Hospital.
Shoppee, Sidney Edward, L.R.C.P. Lond., University College Hospital.
Simpson, Cecil Butler, L.R.C.P. Lond., St. Thomas's Hospital.
Smith, Frank Addinsell, L.R.C.P. Lond., St. Bartholomew's Hospital.
Sparrow, George Randal, L.R.C.P. Lond., University College, and Royal Infirmary, Liverpool.
Stamper, Geoffrey Cooke, L.S.A. Lond., Guy's Hospital.
Stonehouse, Henry, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Stuart, Walter Lea, L.R.C.P. Lond., Guy's Hospital.
Thornton, Frank Butler, L.R.C.P. Lond., St. Thomas's Hospital.
Trotter, Robert Hale, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Tyson, Wilson, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Wakefield, Christopher Frank, L.R.C.P. Lond., Guy's Hospital.
Watson, Frederick James, L.R.C.P. Lond., Cambridge University and St. George's University.
Wilde, Alfred Neville, L.R.C.P. Lond., St. Bartholomew's Hospital.
Williams, Fenwick D'Arcy More, L.R.C.P. Lond., University College, and Royal Infirmary, Bristol.
Willmore, William Southwick, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham.
Wilson, Horace Bagster, L.R.C.P. Lond., University College and General Hospital, Bristol, and Mason College, Birmingham.
Wolfenden, Henry Charles, L.R.C.P. Lond., Mason College, Queen's and General Hospitals, Birmingham.
Wood, Robert Moorsom, L.R.C.P. Lond., King's College, London.
Worthington, John Vigers, L.R.C.P. Lond., London Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the under-mentioned subjects :—

Surgery.—F. R. Baker, London Hospital; G. P. Y. Hulbert, Birmingham; P. G. Lodge, Leeds and St. Thomas's Hospital; D. Pettigrew, Glasgow and Sheffield; W. O. Piper, Westminster Hospital; E. A. B. Poole, Birmingham; E. H. Tipper, Guy's Hospital; J. B. Wall, St. Mary's Hospital; I. Watts, Manchester; H. C. Wimble, St. Bartholomew's Hospital; J. Winder, St. Mary's Hospital.
Medicine, Forensic Medicine, and Midwifery.—W. Benton, Charing-cross Hospital; E. G. Frederick, King's College Hospital; R. B. Jones, Liverpool; J. A. K. Renshaw, Cambridge and Manchester.
Medicine and Forensic Medicine.—F. E. Bromley, London Hospital; C. W. Moorshead, Guy's Hospital; E. H. Tipper, Guy's Hospital.
Medicine and Midwifery.—F. R. Baker, London Hospital.
Medicine.—W. H. Reed, Bombay and King's College Hospital.
Midwifery.—R. P. H. Whitmarsh, St. Thomas's Hospital; J. G. Owen, Charing-cross Hospital.

To Messrs. Hulbert, Lodge, Moorshead, Pettigrew, Poole, Reed, Renshaw, Tipper, Watts, and Whitmarsh was granted the diploma of the Society entitling them to practise Medicine, Surgery, and Midwifery.

NATIONAL DENTAL HOSPITAL.—Under the presidency of Sir Dyce Duckworth, past and present students of the National Dental Hospital gathered in the Holborn Restaurant on Nov. 22nd on the occasion of their annual dinner. Among those supporting the chairman were Sir James Crichton Browne, Mr. James Maughan, Mr. George Cunningham, Mr. Christopher Heath (President of the Royal College of Surgeons of England), Mr. W. R. Humby, Mr. H. J. Relph, and Mr. Sidney Spokes (Dean of the College). An exceedingly encouraging report was presented. Sir Dyce Duckworth referred to the wonderful change that had come over the profession of dentistry in the past quarter of a century, and compared the social position and scientific attainments of those who practised the calling nowadays with the status they occupied then. As matters now stood, a very fair field was opened to all who entered the profession. In a humorous speech Sir J. Crichton Browne said he thought there ought to be a definite scale of charges for dentists, so that people might not be as apprehensive about the extraction of the fee as the extraction of the fang. The recent association between hairdressing and dentistry was a striking testimony to the gullibility of the public, and now that ferocious and unscrupulous barbers had taken to teeth-scaling there was no reason why bootmakers should not claim to be able to treat their customers for gout, or why hatters should not diagnose the softening of their clients' brains while measuring them for their headgear. During the evening the prizes were presented to the successful students.

THE DIFFUSION OF SMALL-POX.—The week ended Nov. 23rd was, like its immediate predecessor, free from fatal small-pox so far as London was concerned. Indeed, the only one of the Registrar-General's thirty-three great towns in which a death was registered from the disease was West Ham. In that borough there has been a continuance of cases diagnosed as small-pox, and some of these have been returned from the hospital ships of the Metropolitan Asylums Board as not being small-pox. Including cases arising in West Ham, there were last week 20 admissions to the ships as compared with 29, 14, and 23 in the three preceding weeks. The close of last week found 89 patients remaining under treatment in the ships as against 106, 79, and 86 on the three previous Saturdays. No cases were heard of in the suburban districts. A few cases of small-pox have occurred recently at Fugglestone St. Peter, in the neighbourhood of Salisbury, but all are now convalescent, having been treated in a temporary hospital resorted to in the emergency. In the west, a case has developed in the Barton Regis Workhouse, near Bristol, the infection being thought to have been conveyed by some visitor. In Dublin, in the week ended Nov. 16th, there were three admissions to hospital, 4 discharges, and 2 deaths, leaving 11 cases under isolation, as compared with 18, 16, and 14 on the three Saturdays preceding. Of the deaths 1 occurred in a vaccinated and 1 in an unvaccinated adult. In Glasgow there have of late been several cases, and many of them have been traced to the spread of infection by mild and unrecognised cases of the disease in the city. The cases were found to have no apparent connexion one with the other. This circumstance led to inquiry, with the result of discovering that cases had arisen which had been considered to be chicken-pox. The medical men of the city have been apprised by the town council of the fact that there is a mild type of small-pox difficult to differentiate from chicken-pox.

NEWPORT (MON.) INFIRMARY—A MUNIFICENT OFFER.—For a considerable time past it has been felt by medical men and others connected with the Newport (Mon.) Infirmary that the site was very unsuitable for a hospital. Still, from time to time costly additions have been made. Now the necessity for further extension has been recognised, and, deeming the moment opportune for considering the question of removal, Dr. and Mrs. Garrod Thomas, the former of whom is honorary physician to the institution, have offered to give £5000 towards the erection of a new building. The offer is conditional upon £15,000 being subscribed by the public apart from the site. Not only does the offer remain open for three years, but the munificence of Dr. and Mrs. Thomas is not absolutely dependent upon the whole amount being raised. For every clear £3000 raised £1000 will be added by Dr. and Mrs. Thomas.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—On Tuesday, November 19th, the students' annual dinner was held at the Criterion Restaurant, under the presidency of Mr. Spencer, the dean of the school. A large company were present. Besides past and present students many of the hospital staff attended, including Dr. de Havilland Hall, Dr. Donkin, and Mr. Bond. After the usual toasts had been proposed and responded to several members of the company sang or recited. The recitation of Captain Cato, one of the guests, descriptive of the career and character of Napoleon, was very effectively rendered; and a humorous sketch given by Mr. Glassington afforded much amusement. Mr. Ormsby's song, "The Doctor," took immensely, as did also "I Can't Change It," which he sang in response to an encore. Mr. Riley's song, "The Four-horse Char-à-banc," was received with loud applause. The dinner was a decided success, and the vote of thanks was no merely formal one which was passed to the honorary secretaries of the dinner, Messrs. Scott and F. J. Bond, for the excellent arrangements which they had made.

BEQUESTS AND DONATIONS TO HOSPITALS.—Sir Frederic Wigan has contributed £500 to Guy's Hospital, London, in response to the recent urgent appeal for funds. Mr. Charles Morrison has also sent a donation of £1000, and Messrs. Glynn, Mills, Currie, and Co., London, have likewise contributed £500.—The late Mr. Charles Overton of Croydon has bequeathed £1000 to the Croydon General Hospital.—The Goldsmiths' Company has made a grant of £100 to Queen Charlotte's Lying-in Hospital, Marylebone-road.—The Fishmongers' Company has granted a donation of 50 guineas to the Royal Westminster Ophthalmic Hospital.—The late Mr. John Lysaght of Bristol has bequeathed £250 each to the Bristol Royal Infirmary, the Bristol General Hospital, and the Bristol Dispensary, Castle-green.—Mr. D. J. MacRae, the editor of the *Financial Times*, has contributed £250 each to the following institutions—namely, the University College Hospital, the *Dreadnought* Seamen's Hospital, the Brompton Hospital, the Cancer Hospital, the East London Hospital, the National Hospital for the Paralysed and Epileptic, and the Jewish Hospital.—The Goldsmiths' Company has contributed £100 to the Extension Fund of the Miller Hospital and Royal Kent Dispensary.—Mr. Henry Harben, J.P., has presented £1000 to the funds of the North London Hospital for Consumption at Hampstead.—The late Mr. Charles Mitchell of Newcastle-on-Tyne has bequeathed £1000 to the Walker Hospital or Infirmary (not the Fever Hospital lately built by the Newcastle-on-Tyne Corporation).—Mr. C. E. S. Cooke, late of Doncaster, has bequeathed £1000 to the Doncaster Infirmary and £500 to the Scholfied Convalescent Fund.—Mr. Cecil Rhodes has given a donation of £1000 to the funds of a new sanatorium at Kimberley.—The late Mr. George Charles Benn of Rugby has bequeathed £1000 to the Northampton Infirmary and £500 each to the Midland Counties' Home for Chronic and Incurable Diseases at Leamington, the British Home for Incurables, the Birmingham and Midland Counties' Eye Hospital, the Birmingham General Hospital, and the Royal Hospital for Incurables.—An anonymous donor has given £1000 to the Royal Portsmouth Hospital.—Major A. W. Holmes, late of Derby, has bequeathed to the Derbyshire Royal Infirmary £100.—The treasurer of the Metropolitan Hospital, Kingsland-road, has received £140 as the result of the concert recently given at the Highbury Athenæum.—Mr. James Stables, J.P., of Horsforth, has sent a donation of 100 guineas to the Leeds Dispensary.

A NEW ROUTE TO EGYPT.—The International Sleeping Car and European Express Trains Company, 14, Cockspur-street, S.W., announce the organisation of a new weekly service *de luxe* from London *viâ* Ostend and Vienna to Trieste for Alexandria. The train will be composed exclusively of sleeping and dining cars and through baggage vans, and will run through from Ostend to Trieste without change. At that port it will connect with one of the steamers of the Austrian-Lloyd Company. The service will leave London every Sunday at 10 A.M., Trieste every Tuesday, and will arrive at Alexandria every Saturday at 4 P.M. On the return journey the steamer will leave Alexandria every Saturday at 9 A.M. The train *de luxe* will leave Trieste every Wednesday on arrival of the steamer, and will arrive in Ostend and London every Friday. The first departure from London will be on Sunday, Dec. 1st, and from Alexandria on Saturday, Nov. 30th.

LIVINGSTONE COLLEGE.—Livingstone College was opened at Bow in 1893 for the purpose of giving to missionaries who intend to labour in uncivilised countries an elementary knowledge of medicine and surgery. It is not intended to train "medical missionaries," and the students are prohibited from taking this title or otherwise assuming the position of qualified medical men. The object of the teaching given at the College is that they may be in some degree enabled to care for their own health and that of their fellow missionaries when far from medical aid, and to deal with the more simple diseases of the natives among whom they may be working. The original building having become insufficient for the number of students, a large double-fronted house was acquired at 31 and 33, Hamfrith-road, Stratford, E., and was formally opened on Nov. 22nd in the presence of a numerous company. In addition to systematic lectures the course of instruction includes clinical instruction at West Ham, Poplar, and the Seamen's hospitals. The bankers are Messrs. Barclay and Co., Lombard-street.

DIPHTHERIA IN LONDON.—The amount of diphtheria occurring in London during recent weeks has shown much increase, as evidenced by the records now to hand for the four-weekly period ended Nov. 2nd. In that period the notified cases in the county of London totalled to 1305, or a weekly average of 326 cases, as compared with 1178 in the preceding like period, with its weekly average of 295 attacks. In the earlier period there were 41 of the forty-three sanitary areas invaded, and in the later period forty-two districts notified attacks—the nine areas with upwards of 50 attacks notified respectively in the earlier period, with their total of 682, giving place to eight such districts in the later period, with a total of 655 attacks. Six of these eight districts were south of the Thames or in the east of London; but the northern districts of St. Pancras and Islington were both heavily affected, but, of course, they are large and populous areas. During the week ended Nov. 16th the registered deaths fell from their high total of the previous two weeks, being 61, against 61, 72, and 75 in the three weeks preceding. All of them were in persons aged under twenty years, and in their aggregate exceeded the decennial average for the forty-sixth week of the years 1885–94 by 21. There were 7 deaths credited each to St. Pancras, Mile End Old Town, and Camberwell sanitary areas. In the outer ring of London there were other 11 deaths from the disease, and of these 8 occurred in the West Ham District. The admissions to London hospitals in the week numbered only 104, as against 115, 102, and 112 in the three previous weeks, but these were, of course, greatly below the cases newly arising in London, and show that very large proportions of the attacks are simply left in the houses where they arise. In the week ended Saturday, Nov. 23rd, the registered deaths from diphtheria in London rose again to 89 in number, and were 27 in excess of the corrected decennial average for the particular week. As many as 9 were in persons belonging to Poplar, 6 to St. Pancras, and 5 each to Kensington and Greenwich sanitary areas, and the disease was once more in its fatal aspect almost wholly confined to children and young persons under twenty years of age. The admissions of diphtheria patients to hospital during the week numbered only 103, and those remaining under treatment at its close (688) were but slightly in excess of previous weekly totals. In Greater London the diphtheria deaths registered were 15, West Ham district claiming 8 of these and Edmonton 3, the remainder belonging to southern and western suburban districts.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATION.—The following gentlemen having passed the necessary examination have been admitted Fellows of the College: Mr. Thomas Eaglesón Gordon and Mr. George Ainslie Johnston. The following gentlemen passed the primary part of the examination: Mr. Patrick Joseph Fagan and Mr. David Alexander M'Curdy.

FOOTBALL CASUALTIES.—While playing recently in a match at Bristol, in the Junior Cup ties, a member of the Waverley Football Club sustained a compound fracture of his leg, and was admitted to the Bristol Royal Infirmary.—A young man aged twenty years died last week in the Bristol Royal Infirmary from injuries received to his head in a match recently played between the Edmondes Trust Old Boys' Club and the Unity Club.—On the 16th inst., a youth, during a game in Christ Church Meadow, Ware, dislocated his ankle and fractured his leg, and was removed to the Hertford General Infirmary.—A young man, a student at the Queen's Engineering Works, Bedford, was found dead in bed on Sunday morning last. He received a kick in the head while playing in a match on the previous day, but as the injury was not regarded as very serious he continued playing for some time afterwards and had no medical assistance.

ANNUAL MEETING OF UNIVERSITY COLLEGE, BRISTOL.—The annual meeting of the governors of University College, Bristol, was held last week, the Bishop of Hereford (Dr. Percival) presiding. It was unanimously decided to confer the chair of Emeritus Professor of Medicine, Midwifery, and Surgery upon Dr. Shingleton Smith, Dr. J. G. Swayne, and Mr. N. C. Dobson, F.R.C.S., respectively. The council in their report show an adverse balance of £950 for the past year, and a total debt of £6000, this debt being chiefly due to building. The endowment of the College is £75, and the only sources of income besides tuition fees are the Government grant of £1200 and the sustentation fund. The annual subscriptions have been reduced by deaths and other causes from £1200 to £500. The council suggest that an earnest appeal should be made, with the double object of relieving them from the existing debt and of restoring the sustentation fund to the original amount—that is, to an equality with the Government grant. It was stated that the council had received offers of liberal support from some citizens, and it is thought that others will be glad to have an opportunity of helping to place the finances of such an excellent institution as the College upon a sound basis. The annual distribution of prizes to the students of the medical school in connexion with University College, Bristol, took place on Nov. 20th, when Mr. N. C. Dobson, Emeritus Professor of Surgery, delivered an address on the Relation of the Medical Man to his Patients, to the Public, and to his Profession. The Bishop of Hereford also spoke.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BRAKENRIDGE, F. J., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

BURGOYNE, J. T., L.R.C.S. Irel., has been appointed Medical Officer to the Helensburgh Coal Mine, New South Wales, vice Lovegrove, resigned.

CONFORD, G. J., B.A., M.B., B.Ch. Oxon, L.R.C.P., M.R.C.S., has been reappointed Assistant House Surgeon to St. Thomas's Hospital.

CORNWALL, J. W., M.A., M.B., B.C. Cantab., has been reappointed Clinical Assistant in the special department for Diseases of the Throat at St. Thomas's Hospital.

CROUCH, H. C., L.R.C.P., M.R.C.S., has been reappointed Assistant House Surgeon to St. Thomas's Hospital.

DALE, FREDERIC, M.D. Cantab., F.R.C.S. Eng., has been appointed Honorary Consulting Surgeon to the Scarborough Hospital and Dispensary.

DAVIS, H. J., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., has been reappointed House Surgeon to St. Thomas's Hospital.

DAWNAY, A. H. P., L.R.C.P., M.R.C.S., has been appointed Junior Ophthalmic House Surgeon to St. Thomas's Hospital.

DIXON, W. B., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed Resident House Physician to St. Thomas's Hospital.

Births, Marriages, and Deaths.

BIRTHS.

BATES.—On Nov. 21st, at Church-road, Upper Norwood, the wife of J. Curling Bates, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

BARLOW.—On Nov. 23rd, at Dalston-lane, N.E., the wife of Thos. Geo. Barlow, L.R.C.P. Edin., of a daughter.

CLARKSON.—On Oct. 31st, at Nasik, Bombay, the wife of Surgeon-Lieutenant-Colonel J. W. Clarkson, of a son.

EAST.—On Nov. 25th, at St. Clare, Great Malvern, the wife of C. E. East, M.D. Durh., of a daughter.

EVELYN.—On Nov. 14th, at 24, Micklegate, York, the wife of W. J. Evelyn, M.D., of a daughter.

HICKS.—On Nov. 19th, at Wymeswold, Leicestershire, the wife of Edward Harman Hicks, M.R.C.S., of a daughter.

MENZIES.—On Nov. 23rd, at Brook House, Godalming, the wife of D. J. Menzies, M.B., C.M., L.R.C.S. Edin., of a daughter.

SIMPSON.—On Nov. 25th, at The Avenue, Eastbourne, the wife of W. Simpson, M.D. Aberd., M.R.C.P. Lond., Calcutta, of a son.

SLAUGHTER.—On Nov. 25th, at Darwen Bank, Darwen, the wife of J. W. Slaughter, Surgeon R.N., H.M.S. *Hibernia*, Malta, of a son.

STEVENSON.—On Nov. 22nd, at The Crescent, Teignmouth, the wife of W. D. Stevenson, Surgeon, late of Wonston, Hants, of a son.

WYNNE.—On Nov. 22nd, at East Kirkby, Notts, the wife of Fred. J. Wynne, M.B. Dubl., of a son.

MARRIAGES.

ADAMS—PRINCE.—On Nov. 21st, at Christ Church, Westminster, Alfred Adams, M.B., B.C.L. Oxon, son of the late Rev. John Adams, Vicar of Stockcross, Newbury, Berks, to Maud Muriel Prince, daughter of the late Dr. Prince, of Great Bedwyn, Wilts.

BARNES—ALLAN.—On Nov. 21st, at St. Augustine's Church, Honor Oak, S.E., Leonard Stewart Barnes, M.R.C.S., L.R.C.P. Edin., of Watford, Herts, to Emily Allan, elder daughter of the late Charles Harrison Allan, of St Catherine's Villa, Tyson-road, Forest Hill, S.E.

COLLINS—CROSSLEY.—On Nov. 20th, at St. James's, Armside, Arncliffe, Ward Collins, M.B. Vict., of Ulverston, to Florence, second daughter of the late John Crossley, of Beechwood, Arnside, Westmorland.

DAVIDSON—LEWER.—On Nov. 20th, at St. Thomas's, Portman-square, Surgeon-Captain John Stewart Davidson, M.B. Aberd., Army Medical Staff, eldest son of A. Davidson, M.D., F.R.C.P.I., of Edinburgh, to Ethel Caroline May, eldest surviving daughter of Surgeon-Major-General Lewer, Army Medical Staff (retired).

PARSONS—GILL.—On Nov. 25th, at Holy Trinity Church, St. Kilda, Melbourne, Australia, Harry Compton-Parsons, M.R.C.S. Eng., L.R.C.P. Lond., of Kalapoi, Christchurch, New Zealand, to Lucretia Halley, second daughter, of the late G. E. Gill, of Batchacre Lodge, Hampton Wick. (By cable).

PATERSON—AITCHISON.—On Nov. 18th, at the British Consulate, Vienna, by the Rev. W. H. Hechler, Embassy Chaplain, James V. Paterson, M.A., M.B., C.M. Edin., to Susie, second daughter of the late John Robert Aitchison, India Office, London.

WILKINS—SLEAP.—On Nov. 19th, at St. Philip's Church, Sydenham, Thomas Herbert Wilkins, L.R.C.S. Irel., L.A.H.I., of Limesdale-road, Clapham-common, S.W., to Theresa, youngest daughter of Charles Sleap, of Longton-grove, Sydenham, S.E.

DEATH.

BREMNER.—On Nov. 25th, at Streatham, Canaan-lane, Edinburgh, Bruce Allan Bremner, M.D., L.R.C.S. Eng., late of Bombay, in his 78th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2 30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY.—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Mr. L. Matheson: A few Practical Points. Casual Communications:—Professor Miller (of Berlin): The Transparent Zone in Dentine.—Mr. Henry L. Albert: A Case of Fracture in a Replanted Tooth.

SOCIETY OF ARTS.—8 P.M. Mr. W. Worby Beaumont: Mechanical Road Carriages. (Cantor Lecture.)

TUESDAY.—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Adams: A new form of Steriliser and Incubator.—Dr. Rolleston: (1) Adenoma of the Sebaceous Glands; (2) Dilatation of the Œsophagus.—Mr. Hutchinson, Jun.: (1) Gall-stone impacted in Small Intestine; (2) The formation of Intra-abdominal Bands; (3) Traumatic Separation of Epiphysis of Great Trochanter.

WEDNESDAY.—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Papers:—Mr. J. Bland Sutton: On a case of Tubo uterine Pregnancy; Primary Intra-peritoneal Rupture; Recovery.—Dr. A. E. Giles: A case of Uterus Didelphys, with Remarks on the Clinical Importance of this Malformation.—Dr. Remfry: The Effects of Lactation on Menstruation and Impregnation.

SOCIETY OF ARTS.—8 P.M. Third Ordinary Meeting. Mrs. Anna Lea-Merritt and Prof. W. C. Roberts-Austen: Mural Painting, with the Aid of Metallic Oxides and Soluble Silicates.

THURSDAY.—HARVEIAN SOCIETY.—8.30 P.M. Dr. M. Handfield-Jones: The Heart in its Relation to Pregnancy, Parturition, and the Puerperal State. (Harveian Lecture.)

FRIDAY.—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road).—8.15 P.M. Clinical Meeting. Cases and Specimens by Drs. Herschell, R. K. Brown, Morgan Dockrell, Ezard, Messrs. Johnson Smith, Poland, the President, and others.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, W.).—8.30 P.M. Clinical Evening. Dr. Taylor: (1) Myxœdema; (2) Deformity of Pinnæ.—Mr. Keetley: (1) Radical Cure of Hernia with Undescended Testicle; (2) Loss of Memory associated with Ovarian Tumour.—Mr. Paget: (1) Resection of Elbow; (2) Fracture of Sacrum.—Dr. Abraham: (1) Primary Chancre in a Child aged eighteen months; (2) Congenital Syphilis.—Mr. Bidwell: Sclerosis of Superior Maxilla.—Mr. Eccles: Multiple Exostoses.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY.—LONDON SKIN HOSPITAL (Fitzroy-square, W.).—8 P.M. Mr. James Startin: Alopecia Areata Parasitica.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

HOSPITAL FOR CONSUMPTION, &c. (Brompton).—4 P.M. Dr. Hector Mackenzie: Thoracic Aneurysm.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—5 P.M. Dr. Morgan Dockrell: Neuroses of the Skin.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. Seymour Taylor: Cardiac Affection in Children.

SATURDAY.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—5 P.M. Dr. Morgan Dockrell: Adenoma Sebaceum.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"HOUSE PROPERTY IN ISLINGTON AND THE VESTRY OF ST. MARY."

To the Editors of THE LANCET.

SIRS,—I have, in common with all owners of London house property, read with great interest your article on the present serious difference of opinion between the medical officer of health for St. Mary, Islington, and the principal ratepayers of that parish. I quite agree with you that the medical officer's chief object should be to make his district sweet and healthy, and it is quite possible for him to secure this object by a wise and temperate use of the powers given to him by the Public Health Acts without undue friction between himself and the inhabitants and house owners of his district. But at the present time the provisions of the Acts, coupled with the by-laws of the London County Council and the local by-laws, are being drastically enforced in Islington to the very letter of the law.

In order to remove any erroneous impression from the minds of your readers, I wish to make it plain that it is not suggested for a moment that the company owns property of the class generally known as "insanitary." All our houses are in wide streets, with gardens in front and rear, and I have been informed by Mr. Leggatt, the superintendent of the Sanitary Department, that during the recent house-to-house inspection of the parish no complaint was found in respect of any of our houses, nor as a result of that inspection was a single nuisance notice served on our property. Therefore, so far as we are concerned, we only suffer on the question of re-drainage; and here I must beg to join issue with Mr. Harris on the statement contained in his letter to the Local Government Board that "I am cognizant of the fact that all notices served were so served in consequence of infectious disease or through complaint." As a matter of fact, no intimation whatever is given to me of the reason a notice is served, and in cases where I have pressed for information the answer has been "a complaint was lodged at the Vestry Hall," but the name of the complainant and the nature thereof is refused.

In cases where I have succeeded in discovering the cause to have been "infectious disease on the premises" the following are fair specimens:—(1) At No. 43, Ronalds-road the infectious disease was a slight case of scarlet fever certified on the day the patient (a lodger's child) entered our house, and although I pointed out to Mr. Harris that owing to the period of incubation the disease must have been contracted elsewhere I was compelled to entirely reconstruct the drainage of that house. (2) At 19, Dean-street a man living at the house cut his hand whilst working at his trade, slight erysipelas supervened (another infectious disease), and I was compelled to entirely reconstruct the drainage. (3) At 22, Langdon-road a lodger (undertaker's coachman) had his foot trodden on by his employer's horse, again slight erysipelas, and entire reconstruction of drainage.

It is customary in Islington to require the owner to erect a 4-in. "ventilating shaft and a new soil-pipe in the event of any repair or alteration to a w.c. (if the repair is only putting a new pan to the closet), and this shaft is insisted upon, whether the drain is intercepted or not. It is, in my opinion, a positive danger to health to erect ventilating shafts which, in the absence of an intercepting trap, are in direct communication with the sewers, and in this view I am supported by many sanitary engineers and medical officers. I also complain that when it is proposed to test a drain notice is never given to the owner, and he has no opportunity of being present when the test is applied.

Digitized by Google

On two occasions I refused to do the works until the tests had been applied in my presence, and in one of these cases the result was so faint as to be almost imperceptible, and in the other there was no result obtained.

I understand that the chemical test now used exercises greater pressure and is far more penetrating than sewer gas can possibly be, and from my experience it is evident that no drain constructed more than ten years ago (unless laid at great depth) will stand the present severe test without giving some slight result. It appears to be Mr. Harris's custom to have the test applied whenever a case of infectious disease (however trivial) or a complaint from any person (whether living in the house or not) is notified to him, and if any result, however slight, is obtained the reconstruction of the whole drain is insisted on. No existing ventilating shaft is allowed to stand unless it is (1) 4 in. in diameter; (2) composed of cast-iron of the weight specified in the bye-laws. I have recently had to demolish perfectly sound iron shafts because they were only 2½ in. in diameter, and zinc shafts (although of the proper size) because they were zinc. No drain (when once any part of it is exposed) is allowed to remain unless it is composed of glazed earthenware pipes with cement joints, and, as it was not until the last few years that these materials have been generally used, it follows automatically that every time I fit a ventilating shaft or soil-pipe to a house built over twenty years ago, thereby exposing the upper end of the drain, the whole drain is condemned and has to be reconstructed, although it may have stood the chemical test before being exposed.

I have never in a single instance in Islington been allowed to repair a drain; it is always total reconstruction. These regulations are enforced by the staff of inspectors, and I believe Mr. Harris seldom personally inspects the nuisance complained of. The notice served generally allows seven days to carry out the work, which, if started the day of service, could not be completed in three weeks, and the inspectors are only too ready to issue a summons in the police-court if the slightest delay occurs. I have found the demands of the inspectors as unalterable as the laws of the Medes and Persians, and it is useless to appeal to Mr. Harris for reconsideration of any item of the notice when it has once been served.

Then as to the "complaints" received by the medical officer. These complaints are generally made by dissatisfied tenants or their lodgers. In one case (53, Almorah-road) a lodger was ejected by our tenant for non-payment of rent, and in revenge, after he had left the house, he complained that the drains were out of order. In this case the drain stood the test, but I was compelled to refit two w.c.'s, to put new soil-pipe and ventilating shaft to an unintercepted drain, expending about £15. I can quote numerous other similar cases. In fact, in Islington the sanitary authority has become a perfect "Bogey man." It is impossible to distrain for an arrear of rent because if I do so a complaint is lodged, the drain tested, and I am put to an expense of £30 to £40. If I give a tenant notice to quit I am at once threatened with this dreadful bogey, and in one case the complaint was lodged because I declined to have the paintwork of a parlour grained and varnished to put my tenant on an equal footing with her sister-in-law who lived on the other side of the road, and whose parlour was grained and varnished! My refusal cost me the usual penalty; the inspector was called in, and the drainage entirely reconstructed.

In my experience of the various sanitary bodies in London I find the spirit at the head permeates the whole body, and I am sure if Mr. Harris would assume a more conciliatory attitude towards the house owners, and endeavour to limit his requirements to the abatement of actual nuisances dangerous to health, we should all be anxious to assist him. Depend upon it, Sirs, when the task of providing homes for the working classes ceases to return a fair interest upon the capital invested, the work of the medical officer will be increased tenfold, for the houses will get into the hands of jobbers and brokers, whose only object will be to exact the highest rent and do little or no repairs. The resolution of this Company (concurred in by many of the largest property owners in London) to purchase no more houses in Islington was not taken without very serious consideration.

I shall esteem it a great favour if you can find space in your columns for this letter, as the discussion of the matter in your journal has awakened the widest interest throughout the property market and amongst owners of house property in London.

I am, Sirs, your obedient servant,

ERNEST EDWARDS.

The Metropolitan House Investment and Agency Co., Ltd.,
Eastcheap, E.C., Nov. 22nd, 1895.

To the Editors of THE LANCET.

SIRS,—In your issue of the 16th inst., page 1238, you state that "He [that is, myself] declares that owing to the fads of the sanitary authority property in Islington is hardly worth having. He makes a still more serious charge, which the Islington authorities would do well to call upon him to establish—that they serve notices to do work 'on people which the department knows it cannot enforce by law.'" I still assert the same fact, and have ample evidence to prove my statement. But in to-day's *Standard* we have still more evidence in support of my statement. I refer to the case of the Duke of Devonshire and others *v.* the Islington Vestry, in which evidence was given that "on 13th May, 1894, defendants gave plaintiffs notice, under the Public Health Act, 1891, to expose their drain for examination." This is distinctly a false pretence on the part of the vestry. There is no section in the Public Health Act, 1891, under which sanitary authorities can enforce such an illegal notice. The fact that damages amounting to £[illegible] besides (the at present) unassessed consequential damages, were awarded to the plaintiffs to be paid by the Islington vestry proves the existence of a state of things that certainly requires consideration and inquiry on the part of some higher authority in our system of parish management. It was proved in the case now under review that the vestry itself was guilty of improperly laying down a drain; yet its officers with all the assurance possible, prosecute other people for exactly similar offences. I understand that the attention of the Local Government Board is being directed to this case, with a request that the district auditor may surcharge the members of the Public Health Committee with the damages and costs of this action, as provided by the 2[illegible] Section of the Public Health Act, 1891.

In my opinion, no one should be allowed to act as a medical officer of health unless he has experience of building construction and possesses the D.P.H. degree.—I am, Sirs, yours truly,

C. T. GORD,
(For the Central Property and Equity Investment Co., Ltd.)

Ironmonger-lane, E.C., Nov. 21st, 1895.

To the Editors of THE LANCET.

SIRS,—Referring to your article on the sanitary condition of [illegible] and the action of our medical officer, the following example among many that have occurred—will show how expenses are run up. I resided in one of the first insanitary houses dealt with by Mr. [illegible]. He ordered various alterations in the sanitary arrangements; these had to be done *no less than three times*. The builder simply defied orders. On my remonstrating with him for bringing the [illegible] ventilator round the bedroom windows I was told no medical [illegible] could make him alter its position. Subsequent events proved to the owner's cost the fallacy of this statement and the folly of trying to [illegible] unsatisfactory work passed. Good sanitary work can never be [illegible] but it will be found less expensive than abortive attempts to [illegible] lawful authority in Islington.

I am, Sirs, your obedient servant,

Nov. 20th, 1895. A GRATEFUL RECIPIENT.

ADVERTISING.

To the Editors of THE LANCET.

SIRS,—The enclosed bills are circulated freely. Is such advertising within the limits of professional etiquette? A reply will oblige.

Yours faithfully,

Canonbury. INQUIRER.

*** The following is the text of the enclosed bill in English, a [illegible] counterpart being attached to it:—

"DEAR MR. "20, Horndon[illegible]

"I have the pleasure to inform you that I have obtained the full medical qualifications of this Country and all the rights and privileges attached to them.

"Yours very faithfully,

"MATTHIAS MAX BERNSTEIN,

"Member of the Royal College of Surgeons of [illegible].
"Licentiate of the Royal College of Physicians of [illegible].
"Doctor of Medicine of the University of Moscow.
"Diploma in Public Health of the University of [illegible].

"*Note.*—Special Hours for Diseases of Women: Wednesdays and Saturdays, from 3 to 5 P.M. Confinements attended to."

Many more offensive circulars are issued; but Mr. Matthias Max Bernstein should know that the "full medical qualifications of this country" carry with them obligations, one of which—the obligation not to advertise—is broken by his open letter to persons who are other practitioners' patients.—ED. L.

Observer, who writes upon the subject of "Bulletin Signing," has omitted to enclose his card. We cannot publish a communication of such a nature unless accompanied by evidence of the identity of the writer. We agree with "Observer" in thinking that the source of the degrees should be indicated, and that the publication of bulletins should not involve anything in the nature of an obtrusive advertisement of the practitioners in attendance.

South Africa.—Our correspondent's question is rather vague. In the settled portions of the country would probably offer the best opening, but the life is not an easy one. Application might be made to the Agents-General for Natal, Cape Colony, &c., at the Colonial Office, Downing-street.

Curette.—We regret that we can be of no assistance.

PHOSPHATE OF POTASSIUM IN BRONCHOCELE.

To the Editors of THE LANCET.

SIRS,—In Dr. Gordon Holmes' article in THE LANCET of Nov. 9th he says: "At the German Congress Kocher spoke very highly of thyroid gland and phosphate of potassium." As I have some cases in which I should like to try this treatment, I shall be obliged if you would give further particulars of it. Phos. pot. I can find no reference to in Squire, and I have not at hand Brunton, and I suppose as it is not mentioned in Squire it would not be in Brunton. What is his dose and how given, &c.? Any information would much oblige a thirty years' subscriber.

I am, Sirs, yours faithfully,

Nov. 22nd, 1895. [illegible]

Digitized by Google

TESTICLE *v.* SWEETBREAD.

To the Editors of THE LANCET.

SIRS,—Having occasion a few days ago to suggest some light food for a patient recovering from enteric fever, I ordered him a sweetbread. On my visiting him the following day I was informed that the butcher had sent in "a very nice pair." As I was not aware of the existence of the said organ in pairs, I asked to see them. The nurse thereupon presented a dish on which were two creamy, fleshy, ovoid masses, which had been bisected, and which on inspection I found to be two testicles (sheep's). The dish and its contents were banished; and I think the patient enjoyed the laugh evoked almost as much as he had anticipated enjoying the "nice pair of sweetbreads."

Never having met with "testicular sweetbreads" before, will you inform me if it is usual for the one organ to do duty for the other in domestic economy, although such a reciprocity is not possible in the physical economy? I am, Sirs, yours truly,

South Lambeth-road, Nov. 25th, 1895. J. MILLER.

SUBLUXATION OF THE PENIS.

To the Editors of THE LANCET.

SIRS,—The case related by Surgeon-Captain Fischer of Moradabad is interesting, as there are but few recorded. A few years ago an officer's horse reared and fell backwards with him on the drill ground. I saw him within half an hour in a state of collapse from the injury. On recovery he tried to pass water, but failed. An attempt to pass a catheter also failed. The penis had disappeared; there was only an empty bag of skin. I made an incision over the pubes, reclaimed the lost organ, pushed it through its sheath, circumcised the long prepuce, and stitched the ragged mucous collar surrounding the glans, after fastening its edges, to the skin. The whole united perfectly. He has since married. I am, Sirs, yours truly,

T. WHITEHEAD REID,
Surgeon to the Kent and Canterbury Hospital.

Canterbury, Nov. 23rd, 1895.

THE PHONENDOSCOPE.

To the Editors of THE LANCET.

SIRS,—Will some of your readers who have made a trial of the "Phonendoscope," an instrument of auscultation lately advertised in your paper, be good enough to publish in your columns the results of their experience with it. The firm advertising the instrument decline to allow a trial, but write me that they have sold some to medical men "of all kinds" (*sic*), who are quite pleased with it. Remembering the great advance the binaural stethoscope was over the old wooden instrument, one would gladly welcome any trustworthy mechanism that would still further intensify our aural powers of diagnosis, but it is not likely that practitioners who know anything of the world will play the "game of confidence" with even a reputable firm of druggists, in spite of the fact that "the outlay is not serious."

I am, Sirs, yours faithfully,

Nov. 27th, 1895. W.

"THE BRITISH MEDICAL BENEVOLENT FUND."

To the Editors of THE LANCET.

SIRS,—I am happy to state that we have been able to make grants amounting to £161 at the meeting of the committee to-day, and I have still to acknowledge with very grateful thanks the following donations.

Dr. Travers	£5	5	0	Mr. Edmund Owen ...	£2	2	0
Mr. John King (per Dr. Travers	50	0	0	Mr. Brook	0	10	6
				Mr. Wilfred Thomas ...	0	10	6

I am, Sirs, yours faithfully,

Brook-street, W., Nov. 26th, 1895. W. H. BROADBENT.

DIET IN GOUT.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me from what source, *re* his diet, must the subject of hereditary gout anticipate the worst results? Do meats vary in the amounts of "nuclein-products" derivable from them in a goutily disposed individual? Does the "boiling" of meat (any meat) lessen the probability of the formation of such products? Is there generally admitted ground for the prohibition of beef from the diet of those whose urine contains a constant excess of uric acid?

I am, Sirs, yours faithfully,

Nov. 11th, 1895. CONSTANT READER.

WANTED, A HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of an establishment where a patient disabled by osteo-arthritis in hip and shoulder would be eligible for admission? The man in question is an ex-soldier, and his wife is able to contribute something towards his support.

I am, Sirs, yours faithfully,

Nov. 27th, 1895. J. SCOTT CHALLICE, L.S.A.

WANTED, A MILK STERILISER.

To the Editors of THE LANCET.

SIRS,—Can any reader supply me with the name of the maker of a cheap milk steriliser, one to contain several small bottles preferred?

I am, Sirs, yours faithfully,

Nov. 28th, 1895. ENQUIRER.

A SELF-THREADING SHUTTLE.

OUR attention has been called by Mr. Joseph Harrison, L.R.C.P. & S. Edin., to a new shuttle which has been introduced into this country from America by Mr. C. H. Holdsworth of Bradford. In the end of the shuttle, which contains the feed-eye, but in the front of it, is cut a narrow groove or recess, and this groove acts as a channel to guide the thread to a twisted copper wire so arranged that the mere looping of the thread over the wire and a slight backward pull are sufficient to bring the yarn up through the feed-eye. The cost of the invention will not add more than a penny to the price of the shuttle, and in view of the fact that a great deal of suffering and disease will be prevented by its use it should be adopted by all textile manufacturers. In the old style of shuttle the thread is sucked through its eye by the operator's mouth, thus furnishing a means of transmitting disease from one person to another. A further reason for its adoption is the lessened liability of the operatives contracting pulmonary disease by the inhalation of fluff from the shuttle.

F. A.—We never recommend individual practitioners. Our correspondent is suffering from a very common malady, upon the proper treatment of which every qualified medical man can advise him. If he requires further assistance, he should ask his regular attendant to recommend him to a consulting opinion.

Dr. Chas. Gross.—The paragraph in question is so ridiculous that it does not need contradiction in our columns, but only in places where it could by any possibility be believed and so work to the detriment of the profession.

Mr. P. F. Sturrage.—We regret that our correspondent's statement has been mislaid. If he will kindly repeat it we shall be glad to answer his inquiries.

"IMPORTANT NOTICE."—AN EXPLANATION.

To the Editors of THE LANCET.

SIRS,—My attention having been drawn to a paragraph in your issue of the 23rd inst., referring to a handbill in which my name appears, I shall be glad if you will publish the following explanation.

Early this month I engaged a consulting room at Mr. Hailstone's and made arrangements to attend at the hours specified. I had nothing whatever to do with the publication of the circulars, the simple fact being that Mr. Hailstone was then about to announce the arrangement he had come to with a dentist, and concluded he could equally well announce the opening of my consulting room at the same address. I repeat that I had no part either in the drafting of the handbill or its distribution, and so soon as I became aware of its existence I requested Mr. Hailstone to withdraw it from circulation, which was done at once.

I am, Sirs, yours faithfully,

Camberwell-road, S.E., Nov. 28th, 1895. MORRIS JENKINS.

WANTED, A LANTERN AND SLIDES.

To the Editors of THE LANCET.

SIRS,—Where can I obtain a magic lantern and slides to illustrate a lecture on the protozoa and the life-history of a sponge?

I am, Sirs, yours faithfully,

Nov. 27th, 1895. J. H. T.

*** In THE LANCET of Feb. 9th, 1895, p. 387, will be found the names and addresses of several firms from whom "J. H. T." will obtain all that he requires.—ED. L.

ERRATUM.—We regret that in Dr. Alexander Morison's article on "The Causes of Bradycardia," in last week's number, page 1282, the words "Dr. (now Sir William) Stokes" were printed instead of *Dr. Stokes*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Drogheda Conservative, Border Counties Gazette, Warwick Times, Electrical Review (New York), Eastern Daily Press, Norfolk Standard, Newtownards Chronicle, Hampshire Post, Hastings Observer, South Wales Daily News, Lincoln Gazette, Sheffield Independent, Scotsman, Manchester Evening Mail, Kidderminster Shuttle, Bedford Standard, Bradford Observer, Leicester Daily Post, Sussex Daily News, North Star, Newcastle Courant, Lynn Advertiser, Brighton Gazette, Times of India, Pioneer Mail, Builder, Architect, Liverpool Daily Post, City Press, Leeds Mercury, Belfast News Letter, Cheltenham Chronicle, Hull Daily News, Buchan Observer, Morning Post (Allahabad), Colchester Mercury, Westmoreland Gazette, Retford Herald, Mining Journal, Reading Mercury, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, St. Bartholomew's Hospital Journal, Truth, Local Government Journal, Surrey Times, Australasian Medical Gazette, Guy's Hospital Gazette, Surrey Advertiser, Essex Weekly News, Buckingham Express, Whitehall Review, Le Courrier de la Presse, Acton and Chiswick Gazette, Hunts County News, Pullen's Kent Argus, Essex County Standard, Bristol Mercury, Leeds Weekly Citizen, Boston Independent, Craven Herald, &c., &c.*

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Asnieres, Paris.

The Action and Use of Some New Synthetic Remedies.

ANTIPYRIN.

(PHENYL-DIMETHYL-PYRAZOLON.)

THE question regarding the importance of the therapeutic action of antipyrin and other drugs allied to it in action and in structure was referred last year to the Therapeutic Committee of the British Medical Association. Their report indicated that a large amount of practical experience had been obtained concerning the nature and action of Antipyrin and its harmlessness when administered with due regard to dosage and case. Upon its first introduction it was mostly used as an antipyretic, but a consensus of later opinion showed unmistakeably that its principle therapeutic value lay in its effects as a minimiser or remover of pain.

Though the information which the committee obtained regarding the nature of any ill effects of this drug was of the greatest importance theoretically, practically the objections to its use were of slight moment, being due principally to an excessive physiological action of the drug induced probably by errors in its administration.

Antipyrin is a drug capable of relieving intense neuralgic pains of functional origin with a completeness which demonstrates that it possesses a very powerful action on the nervous system and through that on the metabolic processes of the body. As an analgesic it is specially active in relieving those pains caused by nerve storms or which occur in paroxysms. It proves an active analgesic when pain is due to alterations in the posterior column of the spinal cord as it is in the severe lightning pains of Locomotor Ataxia. It is not accurately ascertained how this action comes about, but it has been supposed that Antipyrin acts by distributing sensory impulses over a greater number of brain cells so that the initial impulse which gives rise to the pain is, as it were, modified by being spread over a larger receptive area and is thus diminished or even lost.

Other pains of a spasmodic character—such, for instance, as sciatica, megraine, colic, and some forms of dysmenorrhœa characterised by spasmodic paroxysms of pain—are greatly ameliorated by the action of this drug.

Another group of diseases which come under its influence includes those which are dependent upon nervous irritation or excessive excitability of the motive nerve centres, such, for instance, as croup, chorea, and whooping-cough, in all of which Antipyrin has a sedative action on the irritable nerve cells. In combination with the bromides its effect is said to be enhanced in such disorders as Enuresis. Other nervous disorders of the bladder have also been successfully treated by the administration of Antipyrin.

As a febrifuge, Antipyrin reduces febrile temperature with great rapidity when it is not due to inflammatory processes. It dilates peripheral cutaneous vessels, and thes increases radiation. It also lessens the production of heat, and further diminishes temperature by allowing radiation and by the evaporation of the perspiration which it produces on the skin. It does not, however, act powerfully as a sudorific, but slightly increases the blood pressure. The temperature will remain reduced under the action of Antipyrin for from one to twenty hours. Any subsequent recrudescence of fever is not accompanied by marked rigor. Antipyrin is of great value in many of the specific fevers especially in typhoid and phthisis, but it has also a powerful effect in reducing the temperature in erysipelas, surgical fever, and in many cases of pneumonia.

Antipyrin has been used also as a hæmostatic in a solution of 4 to 5 per cent. It can be injected subcutaneously in half its weight of water, and seems to have a special action on the fifth nerve in severe facial neuralgia. It gives a deep red colour with a solution of perchloride of iron, is incompatible with spiritus ætheris nitrosi or nitrites with which it forms an inert bluish green compound. It is also incompatible with Quinine, it liquifies with Butyl-chloral-hydrate, Salicylate of Soda and B. Naphthol.

It is very conveniently administered in the form of "Tabloids," which are prepared of two strengths—5 grains and 2½ grains. The 2½ grain "Tabloids" are sugar-coated and supplied to the Medical Profession in bottles of 24 and 100 at 8d. and 2s. 1d. each. 5 grain "Tabloids" in bottles of 25 and 100 at 1s. 1d. and 3s. 11d. each.

AGATHIN.

(SALICYL-ALDEHYDE-Â-METHYL-PHENYL-HYDRAZONE.)

Since it was originally discovered by Dr. Ross this drug has been tried with much success as an anti-neuralgic and anti-rheumatic, and found effective when other agents have failed. Recent testimony proves undoubtedly that Agathin may be administered with advantage in Sciatica, in obstinate cases that have resisted other treatment, the pain being speedily and permanently removed. In both articular and muscular rheumatism, also, Agathin has been prescribed with very satisfactory results when Salicin, Salicylates, Sulphur, and the usual run of remedies produced little or no effect. "Tabloids" of Agathin, containing four grains each, are a convenient form of prescribing this drug, two "tabloids" thrice daily being a fair average daily dose for adults. Supplied in 1 oz. tins at 9s. 3d. per oz.; also in 4 gr. "Tabloids," in bottles of 24 and 100 at 2s. 8d. and 10s. each.

ALUMNOL.

(ALUMINIUM-NAPHTHOL-SULPHONATE.)

The physiological action of Alumnol is that of a harmless, odourless, antiseptic astringent, which is capable by reason of its solubility, of exerting a penetrating effect. It may thus be advantageously substituted for the antiseptic astringents hitherto in vogue—for example, nitrate of silver—which are effective only at the surface of contact, because they form insoluble compounds with the albumen of the uppermost cellular layer of the exudation. Alumnol is the aluminium salt of a naphthol-sulphonic acid, containing 15 per cent. of sulphur in the form of the sulphone group and about 5 per cent. of aluminium. It forms a white powder which is very readily soluble, even in cold water (40 per cent. solutions may be made without separation of the salt as standing); it is also taken up by glycerine and hot alcohol, the solution in the latter solvent exhibiting a beautiful blue fluorescence. Alumnol supplied to the Medical Profession at 1s. per oz.; also in 4-gr. "Tabloids" at 8d. and 1s. 6d. per bottle.

BENZOSOL.

(GUAIACOL-BENZOATE.)

It is odourless and tasteless, and yet retains all the valuable properties of Creosote; it must, therefore, be regarded as a real and important step forward in the medical treatment of tuberculosis. The results obtained by Benzosol have been at least equal, if not superior, to those yielded by Creosote. The action of the drug is shown by the relief and decrease in violence of the tormenting fits of coughing; expectoration is lessened in quantity and hectic perspirations disappear. Appetite and the general condition of health steadily improve. Benzosol may, therefore, be regarded as an agreeable and harmless substitute for Creosote, beneficially influencing the general nutrition, and consequently increasing the resistance of the patient to the disease. Benzosol is supplied to the Medical Profession at 3s. 3d. per oz., and in 5 gr. "Tabloids" in bottles of 24 and 100, at 1s. 4d. and 4s. 8d. each.

HYPNAL.

(MONOCHLORAL-ANTIPYRIN.)

Fifteen grains of this substance have been found equal in hypnotic effect to 7½ grains of Chloral Hydrate. It is nearly tasteless and devoid of qualities irritating to the mouth or stomach. It is considered an unrivalled soporific when insomnia is the result of pain or of mental excitement, incipient delirium tremens, or chorea. It is supplied to the Medical Profession at 2s. 11d. per oz., also in 5 gr. "Tabloids" in bottles of 24 and 100 at 1s. 2d. and 4s. 4d. per bottle.

The above products are produced by the Farbwerke vorm. Meister, Lucius, & Brüning, Hoechst-am-Main.

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Asnières, Paris.

Action and Use of Some New Synthetic Remedies.

ANTIPYRIN.

(PHENYL-DIMETHYL-PYRAZOLON.)

THE question regarding the importance of the therapeutic ...on of antipyrin and other drugs allied to it in action and ...tructure was referred last year to the Therapeutic Com...ee of the British Medical Association. Their report in...ted that a large amount of practical experience had been ...ained concerning the nature and action of Antipyrin and ...harmlessness when administered with due regard to dosage ... case. Upon its first introduction it was mostly used as ...ntipyretic, but a consensus of later opinion showed un...takeably that its principle therapeutic value lay in its ...cts as a minimiser or remover of pain.

...hough the information which the committee obtained ...arding the nature of any ill effects of this drug was of the ...atest importance theoretically, practically the objections ...ts use were of slight moment, being due principally to an ...essive physiological action of the drug induced probably ...errors in its administration.

...ntipyrin is a drug capable of relieving intense neuralgic ...ns of functional origin with a completeness which demon...ates that it possesses a very powerful action on the nervous ...tem and through that on the metabolic processes of the ...dy. As an analgesic it is specially active in relieving those ...ns caused by nerve storms or which occur in paroxysms. ...proves an active analgesic when pain is due to alterations ...the posterior column of the spinal cord as it is in the ...ere lightning pains of Locomotor Ataxia. It is not accu...ely ascertained how this action comes about, but it has ...n supposed that Antipyrin acts by distributing sensory ...pulses over a greater number of brain cells so that the ...rial impulse which gives rise to the pain is, as it were, ...odified by being spread over a larger receptive area and is ...s diminished or even lost.

...Other pains of a spasmodic character—such, for instance, ...sciatica, megraine, colic, and some forms of dysmenor...ea characterised by spasmodic paroxysms of pain—are ...eatly ameliorated by the action of this drug.

...Another group of diseases which come under its influence ...ludes those which are dependent upon nervous irritation ... excessive excitability of the motive nerve centres, such, ... instance, as croup, chorea, and whooping-cough, in all of ...hich Antipyrin has a sedative action on the irritable nerve ...ells. In combination with the bromides its effect is said to ... enhanced in such disorders as Enuresis. Other nervous ...sorders of the bladder have also been successfully treated ... the administration of Antipyrin.

...As a febrifuge, Antipyrin reduces febrile temperature with ...eat rapidity when it is not due to inflammatory processes. ...dilates peripheral cutaneous vessels, and thes increases ...diation. It also lessens the production of heat, and further ...minishes temperature by allowing radiation and by the ...aporation of the perspiration which it produces on the skin. ...does not, however, act powerfully as a sudorific, but slightly ...creases the blood pressure. The temperature will remain ...duced under the action of Antipyrin for from one to twenty ...ours. Any subsequent recrudescence of fever is not accom...anied by marked rigor. Antipyrin is of great value in many ...f the specific fevers especially in typhoid and phthisis, but ... has also a powerful effect in reducing the temperature in ...rysipelas, surgical fever, and in many cases of pneumonia.

...Antipyrin has been used also as a hæmostatic in a solution ...f 4 to 5 per cent. It can be injected subcutaneously in half ...s weight of water, and seems to have a special action on the ...fth nerve in severe facial neuralgia. It gives a deep red ...olour with a solution of perchloride of iron, is incompatible ...vith spiritus ætheris nitrosi or nitrites with which it forms ...an inert bluish green compound. It is also incompatible ...vith Quinine, it liquifies with Butyl-chloral-hydrate, Sali...ylate of Soda and B. Naphthol.

It is very conveniently administered in the form of "Tabloids," which are prepared of two strengths—5 grains and 2½ grains. The 2½ grain "Tabloids" are sugar-coated and supplied to the Medical Profession in bottles of 24 and 100 at 8d. and 2s. 1d. each. 5 grain "Tabloids" in bottles of 25 and 100 at 1s. 1d. and 3s. 11d. each.

AGATHIN.

(SALICYL-ALDEHYDE-Â-METHYL-PHENYL-HYDRAZONE.)

Since it was originally discovered by Dr. Ross this drug has been tried with much success as an anti-neuralgic and anti-rheumatic, and found effective when other agents have failed. Recent testimony proves undoubtedly that Agathin may be administered with advantage in Sciatica, in obstinate cases that have resisted other treatment, the pain being speedily and permanently removed. In both articular and muscular rheumatism, also, Agathin has been prescribed with very satisfactory results when Salicin, Salicylates, Sulphur, and the usual run of remedies produced little or no effect. "Tabloids" of Agathin, containing four grains each, are a convenient form of prescribing this drug, two "tabloids" thrice daily being a fair average daily dose for adults. Supplied in 1 oz. tins at 9s. 3d. per oz.; also in 4 gr. "Tabloids," in bottles of 24 and 100 at 2s. 8d. and 10s. each.

ALUMNOL.

(ALUMINIUM-NAPHTHOL-SULPHONATE.)

The physiological action of Alumnol is that of a harmless, odourless, antiseptic astringent, which is capable by reason of its solubility, of exerting a penetrating effect. It may thus be advantageously substituted for the antiseptic astringents hitherto in vogue—for example, nitrate of silver—which are effective only at the surface of contact, because they form insoluble compounds with the albumen of the uppermost cellular layer of the exudation. Alumnol is the aluminium salt of a naphthol-sulphonic acid, containing 15 per cent. of sulphur in the form of the sulphone group and about 5 per cent. of aluminium. It forms a white powder which is very readily soluble, even in cold water (40 per cent. solutions may be made without separation of the salt as standing); it is also taken up by glycerine and hot alcohol, the solution in the latter solvent exhibiting a beautiful blue fluorescence. Alumnol supplied to the Medical Profession at 1s. per oz.; also in 4-gr. "Tabloids" at 8d. and 1s. 6d. per bottle.

BENZOSOL.

(GUAIACOL-BENZOATE.)

It is odourless and tasteless, and yet retains all the valuable properties of Creosote; it must, therefore, be regarded as a real and important step forward in the medical treatment of tuberculosis. The results obtained by Benzosol have been at least equal, if not superior, to those yielded by Creosote. The action of the drug is shown by the relief and decrease in violence of the tormenting fits of coughing; expectoration is lessened in quantity and hectic perspirations disappear. Appetite and the general condition of health steadily improve. Benzosol may, therefore, be regarded as an agreeable and harmless substitute for Creosote, beneficially influencing the general nutrition, and consequently increasing the resistance of the patient to the disease. Benzosol is supplied to the Medical Profession at 3s. 3d. per oz., and in 5 gr. "Tabloids" in bottles of 24 and 100, at 1s. 4d. and 4s. 8d. each.

HYPNAL.

(MONOCHLORAL-ANTIPYRIN.)

Fifteen grains of this substance have been found equal in hypnotic effect to 7½ grains of Chloral Hydrate. It is nearly tasteless and devoid of qualities irritating to the mouth or stomach. It is considered an unrivalled soporific when insomnia is the result of pain or of mental excitement, incipient delirium tremens, or chorea. It is supplied to the Medical Profession at 2s. 11d. per oz., also in 5 gr. "Tabloids" in bottles of 24 and 100 at 1s. 2d. and 4s. 4d. per bottle.

The above products are produced by the Farbwerke vorm. Meister, Lucius, & Brüning, Hoechst-am-Main.

BENGER'S FOOD

For Infants Invalids and the Aged

AWARDS.

GOLD MEDAL, International Health Exhibition, London, 1884.
FIRST ORDER OF MERIT AND MEDAL (Highest Award), Adelaide, 1887.
HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Notice to the Medical Profession.

BENGER'S FOOD is *not* predigested—as appears to be erroneously supposed by some medical men. It consists of a highly nitrogenous wheaten meal, cooked and impregnated with a suitable proportion of the natural digestive principles of the pancreas. When mixed with warm milk, according to the directions on each tin, these principles convert the farinaceous elements of the food into soluble dextrines and sugar; they further modify, but do not fully peptonise the casein of the cow's milk. This modified casein forms small flocculent curds, instead of hard indigestible masses, in the stomach of the infant, the condition of the casein resembling that of human milk. The fat is entirely unaffected. In this way the digestive organs of the infant are merely relieved of the excessive strain placed on them by the ingestion of ordinary Foods, whilst there is abundant work left to ensure their proper development.

The practical experience of those medical men who prescribe it, and of thousands of mothers, has proved that not only does the infant thrive on Benger's Food almost or quite, from birth, but that when the time comes for the gradual substitution of other aliment the digestive organs, instead of being weak and atrophied, are healthy and vigorous, and much better able to perform their functions than those of children whose stomachs have been kept in an irritable condition by unsuitable food.

MEDICAL OPINIONS.

"*Mr. Benger's admirable preparations.*"—THE LANCET, March 25th, 1882.

"*Deserving of the highest praise, and only require to be made known to the profession to ensure their extensive employment.*"—THE PRACTITIONER, February, 1883.

"*Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick.*'—THE MEDICAL PRESS, June 13th, 1883.

"*Benger's Preparations have deservedly a very high reputation and are all largely used.*"—THE MEDICAL TIMES AND GAZETTE, September 8th, 1883.

"*Benger's Food is a preparation, devised on original lines, and which we can speak of in the highest terms. ..... Infants do remarkably well on it, and it is most suitable for many conditions in adults and old people. ..... There is certainly a great future before it.*"—THE ILLUSTRATED MEDICAL NEWS, December 22nd, 1888.

"*Undoubtedly a great advance on any previous attempt in this direction. It is palatable and excellent in every way. We have given it in very many cases with the most marked benefit, patients frequently retaining it after every other food has been rejected. For children who throw up their food in curdled masses it is invaluable.*"—THE LONDON MEDICAL RECORD, March 15th, 1888.

BENGER'S FOOD may be obtained in Tins of leading Chemists, &c., everywhere; wholesale of all wholesale houses, or of

The Bradshaw Lecture

ON

INFECTIVE AND TUBERCULAR OSTEITIS AS CAUSES OF ARTHRITIS IN CHILDHOOD, AND THE IMPORTANCE OF THEIR EARLY TREATMENT.

Delivered before the Royal College of Surgeons of England on Dec. 5th, 1895,

BY N. C. MACNAMARA, F.R.C.S. ENG. AND IREL.,
SURGEON TO THE WESTMINSTER HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—I propose in this lecture to consider how it is that the extremities of the long bones entering into the formation of various joints are peculiarly liable during childhood to become the breeding ground of certain forms of micro-organisms, and so become affected with osteitis, and then to inquire by what means we can best dislodge such parasites before they have destroyed the osseous tissues among which they may have taken root. It will be necessary to confine my remarks to a typical example of acute and of chronic inflammation of bone produced by two well-defined microbes, and to illustrate the subject by reference to disease of the knee. This joint, being one of the largest and most superficial articulations of the body, affords us a favourable opportunity for determining the nature of any morbid action taking place in the bones entering into its formation. The condyles of the femur at each step we take have to bear the weight of the body, which in like manner is supported on the upper surface of the head of the tibia, so that these opposing portions of bone are constantly subjected to considerable pressure and to concussion. This pressure, in consequence of the comparatively soft condition of the osseous tissue in childhood, is largely distributed throughout the trabecular tissue contained within the extremities of the bones which enter into the formation of the joint. The trabecular network within the extremities of the long bones is also subjected to traction, especially at the point of union between ligaments and tendons with the bones; so intimate is this union that in cases of violence tendons not infrequently tear away portions of the cancellous tissue as well as the compact outer layers of the bone into which they are inserted. It follows, therefore, that the trabeculæ contained in the extremities of these bones have to take their share in the frequent wrenches and strains to which the joints of children are subjected, and it is within the meshes formed by the interlacing of these trabeculæ that the red marrow of the bone is contained—red because it is full of blood, and among the other functions which it has to perform is that of manufacturing the red blood corpuscles. Beyond this the trabeculæ are lined with cells from which in childhood the growth of the epiphysis takes place, necessitating active and extremely complicated physiological changes in the organic matter through means of which growth is effected. We may form some idea of the activity of the work going on within the bones entering into the formation of the knee-joint from its abundant supply of bloodvessels; the four articular arteries, the azygos, and branches of the tibial and femoral vessels all send numerous offsets into the bones; in fact, the condyles of the femur and head of the tibia are riddled with openings through which vessels pass into and leave the cancellous tissue. Within the bone the arteries break up into narrow vessels which open into a plexus of peculiarly wide venous capillaries, and these into veins which have to pass out of the bone through the unyielding channels perforating the dense external layers of the bone. The circulation of blood, therefore, through the thin-walled venous capillaries in the marrow of bone is much delayed, and it is in this sluggish stream of blood that the nucleated cells are converted into red blood corpuscles.

Within the cancellous tissue of the long bones we have, therefore, highly vascular and delicate, soft structures through which the circulation of the blood is naturally much impeded, and these tissues during childhood, as already explained, are peculiarly liable to contusion by external force. Beyond this the marrow contains numerous cells through means of which the growth and repair of the bone are effected. We are apt to overlook the important and extremely complex nature of the process of growth; it means a vast expenditure of physiological action, and of an almost inconceivably complicated arrangement of the constituent elements of the organic matter engaged in the process. But the more complicated the machine the less its stability, and consequently the greater the danger of its component parts being disarranged. And it is in organic matter which has been contused, or in which the constituent parts have otherwise been much disturbed and its vitality thus lowered, that micro-organisms take root; and so we can comprehend why it is that the marrow of the cancellous tissue in the ends of the long bones during childhood is not infrequently the breeding ground of various forms of microbes. The vulnerability of the tissues of young persons to microbes is exemplified by the eruptive fevers from which they suffer, in the susceptibility of European recruits to tropical disease or to typhoid fever on their arrival in India. As we advance in life the ends of the long bones become surrounded by layers of dense, unyielding osseous tissue, which to a large extent preserves the soft structures contained within the cancellous tissue from injury; the process of growth has also been completed, and, the tissues having become more stable, acute infective or tubercular osteitis seldom commences in the joints of persons who have passed the age of childhood.

It is hardly necessary to observe that the bones increase in length by the growth of osseous tissue at the juxta-epiphysial line, and that at this line in the growing bone the trabecular network is composed of temporary—that is, of brittle—bone, in which the venous radicles pass up to the epiphysial cartilage, and there form loops more like sinuses than ordinary veins. One or two arteries from the diaphysis pass through the cartilage into the epiphysis, but by far the greatest part of the blood-supply of the epiphysis is independent of that of the diaphysis; in fact, the shaft of one of the long bones may become necrosed and be removed, and yet the epiphysis may continue to live and grow. Muscular force is capable of causing the complete detachment of an epiphysis, and fractures not infrequently occur through this line; short of such extensive injuries, ecchymosis and laceration of the fragile and rapidly growing structures at the juxta-epiphysial line must be of common occurrence in childhood. The circumference of the epiphysial cartilage is prolonged into the deep layer of the periosteum of the diaphysis, and its cells produce the osteoblasts of that layer; the extremities, therefore, of the diaphysis in the growing bones of children are enclosed in a cup-like cavity of cartilage, and if acute inflammation should occur in the tissues at the juxta-epiphysial line, the products of the inflammatory action must find an exit through the trabecular network of the extremity of the diaphysis into the medullary canal, and between the deep layer of the periosteum and the outer surface of the bone; in either case the blood supply of the diaphysis is cut off, the periosteum being stripped from the bone, and the pressure of the inflammatory products against the unyielding trabeculæ and Haversian system prevents the circulation of blood through the shaft of the bone, and it consequently becomes necrosed. But the deep layer of the periosteum, having been forced outwards with the surrounding vascular structures, may continue to live and form a case of new bone around the necrosed diaphysis. Professor Ollier in the year 1881 published the results of some experiments he had made on the dead bodies of children which illustrate the point above referred to; he found that only slight force applied in certain directions was sufficient to injure, and often to lacerate, the soft tissues at the juxta-epiphysial line. If the force was increased the injured structures could without difficulty be squeezed outwards beneath the deep layer of the periosteum, but not into the external soft tissues or round the epiphysis. Professor Ollier also states that in the case of children who had died from tuberculosis or from septic poisoning the structures at the juxta-epiphysial line were peculiarly friable. Without doubt a young and healthy bone, like a branch of a living tree, is a very different thing from the same part after death; but among our poor neglected, anæmic, London-born children the tissues are often, as regards their vitality, not far removed from dead structures. We can readily conceive that the organic matter which forms the bodies of these children is less capable of resisting the attacks of micro-organisms than

Digitized by Google

that of more robust and well-cared-for beings. One seems to realise this difference when before the days of Listerian surgery one saw the swarms of ants and flies which attacked, in a climate like that of Calcutta, the wounds of persons whose vital powers were at a low ebb. And so with micro-organisms, their opportunity is in structures which have been contused or their vitality depressed by some other cause, it is in organic matter of this kind that microbes take root.

Bacteriologists teach us that micro-organisms of a dangerous character may remain quiescent in our bodies, at any rate they can live there without exciting any active disturbance, for they seem to be under the control of constituted authorities which they evidently respect; but if these salutary forces are incapable of performing their functions, or if the microbes alight on a soil composed of weak or injured tissues, they fix themselves on such matter and grow with amazing rapidity, and by means of the irritating chemical compounds they produce set up inflammation in the neighbouring tissues. To illustrate this point we may again refer to the East; there at the end of the hot season we pass over a large expanse of land with no vestige of animal or vegetable life on its surface, the earth is bare, scorched, and fissured in all directions, having for weeks been exposed to the uninterrupted heat of a tropical sun. Suddenly a storm bursts over the country and a deluge of rain falls; with its first drops the whole plain is alive with a multitude of insects and frogs whose loud croaking fills the air; a mere shower of rain has been sufficient to bring a vast amount of dormant life, including cholera and other bacilli, into active being. And so with the human body. I must have swallowed large quantities of water infected with cholera bacilli during my service in Lower Bengal, but on one occasion only, and that from my own fault, they found my intestinal canal unprepared to resist their attack, and then they nearly killed me; the shower of rain had come for them, and they took advantage of it. In like manner we can account for the action of unripe fruit or unwholesome food, saline purgatives, and so on, as predisposing causes of cholera: they prepare the surface of the intestines as a fit breeding ground for the cholera bacillus.

Clinical experience had convinced me some twenty years ago that cases of acute inflammation at the juxta-epiphysial line depended on causes such as those described—that is, to injured tissues which had fallen a prey to a specific microbe. These ideas have since been confirmed by experimental research, for Mr. A. H. Tubby has shown that among animals acute inflammation of the structures forming the juxta-epiphysial line may with certainty be produced if this part be mechanically injured, and then the staphylococci pyogenes aurei are introduced into the circulation of the animal. The result of this treatment is an intense inflammation of the injured osseous tissues, which rapidly swarm with these microbes, leading to dangerous septic poisoning. In animals where similar injuries had been inflicted at the juxta-epiphysial line, but in which staphylococci had not been introduced into the blood, no acute inflammation occurred in the damaged tissues or in any other part of the body. And so if one of our weak city-bred children suffers from traumatism at the juxta-epiphysial line, say at the upper extremity of one of his tibiæ, and if at the same time the part becomes infected by the staphylococci pyogenes aurei, introduced into the circulation probably through some open sore, acute inflammation is produced in the injured bone, so acute and so dangerous that more than half these patients die within the course of a few days. Should the child outlive the onset of the disease pus forms in the inflamed bone, and, for reasons already given, it burrows into the diaphysis and between the deep layers of the periosteum and the bone, leading to necrosis of the shaft of the tibia. In the less severe cases the inflammatory action may be limited and produce a circumscribed and chronic abscess in the extremities of the bone. It is quite possible when the juxta-epiphysial line of the upper end of the tibia is involved that pus may pass into the knee-joint—a condition described and figured by Mr. Thomas Smith in his paper on this subject, published in the St. Bartholomew's Hospital Reports for 1877. In these cases it is probable that the infective micro-organism from the juxta-epiphysial line finds its way along the walls of one of the vessels, which pass from the diaphysis through the epiphysial cartilage and so reaches the joint. However this may be, the knee may become acutely inflamed, but is by no means necessarily involved in cases of acute infective osteitis.

If we rightly comprehend the nature of this form of disease, its treatment would seem to be clearly indicated, for it is evident that we must endeavour to destroy the living organism which is at the root of the mischief. Incision into the periosteum, however important they may be, do not reach the source of the disease; to do this we must open the bone at the juxta-epiphysial line and wash out the infected tissues with a germicide, subsequently maintaining free drainage from the interior of the inflamed bone outwards in antiseptic dressings. We do wrong to wait for pus to form in cases of this description, or to delay opening the bone for an hour after we have diagnosed the nature of the disease; for the micro-organisms which are at the root of the mischief, as a rule, live and multiply with great rapidity in the part, until within a short period they destroy the life of the individual they inhabit, or cause their own death by the suppuration they give rise to in the tissues. The question therefore, as to when we should operate in cases of this description is answered by directing the bone to be opened immediately we have determined the nature of the disease, remembering that the operation is attended with no danger, but if delayed for a few hours it may be too late. In cases of strangulated hernia, and in acute glaucoma, we have come to recognise the fact that so soon as the nature of the disease has been diagnosed we are bound to relieve the constriction in the one case and the tension in the other; so in acute inflammation of the bone, having determined the nature of the disease, not mistaking it for acute rheumatism of the joint, a free opening should be made into the part, the bone must be opened and the focus of the inflammatory action reached, if possible before suppuration has taken place in the osseous tissue. An Esmarch's band having been applied to the thigh in a case such as that we are considering, a free incision is made through the soft tissues down to the epiphysis and along the shaft of the bone so as to expose the juxta-epiphysial line. A trephine about an inch in circumference is then, with a light hand so as not to splinter the bone, to be passed through the whole thickness of the tibia; another incision is to be made through the soft tissues down to the point at which the trephine has perforated the bone, so that a passage is formed through the limb, including the small tunnel in the bone, from either end of which free drainage can take place outwards beyond the surface of the skin. The opening in the bone should be thoroughly and repeatedly washed out with mercurial solution and then filled with iodoform, after which the limb having been packed in antiseptic dressings, the elastic band may be removed from the thigh. As a rule neither drainage-tube nor sutures are required in these cases. The limb should be secured by an interrupted splint so that the dressings may be changed without disturbing the part operated on—in fact, the subsequent treatment of the case is very much that of a compound fracture. If pus has passed into the knee-joint it will be necessary to follow the treatment as regards the inflamed bone already described, and in addition to opening the joint to wash it out with mercurial solution, treating it as we should do an acute abscess in any other part of the body.

The following case is an example of the results of the early treatment of acute juxta-epiphysial osteitis. An infant aged seven months was admitted into the Westminster Hospital under my care on May 9th. She was a delicate little being and suffering from whooping-cough. Thirty-six hours before admission into hospital, there being no history of an injury to the part, the child's right leg became excessively painful and greatly swollen, the infant screaming violently the instant the limb was moved. The child was at once taken to the hospital, and Mr. De Santi, who first saw the case in the out-patient department, ordered her into the wards and that I should be sent for. Some four hours after admission the child's temperature was 104° F. Her right leg from the knee to the ankle was of brawny hardness and exceedingly painful. An incision was at once made down to the bone at the juxta-epiphysial line of the upper end of the right tibia, and a tunnel made through the bone with a trephine—in fact, the patient was treated in precisely the manner already described. The child's temperature on the day following the operation had fallen to 100°, and the next day it was under that point. After three weeks the child was removed into the country, and two months subsequently, when I again saw her, all trace of the osteitis from which she had suffered had entirely disappeared, a result attributable to the fact of the diseased bone having been freely opened and washed out with mercurial solution, and the cavity filled

Digitized by Google

with iodoform, within forty-eight hours after the commencement of the disease.

TUBERCULAR OSTEITIS.

Having described the conditions which render the marrow contained within the extremities of the long bones peculiarly liable to become the breeding ground of micro-organisms, it is unnecessary to enter further into this subject. The question we have to determine is whether the chronic joint disease of childhood depends on tuberculosis of the marrow contained in the extremities of the bones entering into the formation of the affected joint; unless we can satisfy our minds on this point it seems almost impossible to arrive at any rational conclusions as to how we should best treat the early symptoms of such cases. The difficulty surrounding this question arises from the fact that pathological specimens of these joint affections in their early stages are seldom met with, and the osseous tissue is by no means an easy one in which to detect the presence of a few tubercle bacilli, and in the early stages of these diseases of joints only a limited area of bone is involved, and within this area probably only a few bacilli exist. During the past fifteen years in the surgical wards of the Westminster Hospital three children while under treatment for the early stages of scrofulous joint disease developed tubercular meningitis and died. In these three cases (one a knee and the other two hip-joint disease) we had an opportunity of examining the condition of the affected joints at quite the commencement of the disease. In the knee-joint case a spot of inflamed osseous tissue was found at the insertion of the tendon of the extensor muscles to the tubercle of the tibia; in this congested portion of bone tubercles were discovered. In the two cases of hip-joint disease, in inflamed spots of bone near the circumference of the neck of the femur on the distal side of the epiphysial cartilage, distinct tubercles were found, and in these tubercles a few bacilli were detected. The ligaments, synovial membrane, and other joint structures were very carefully examined, but no trace of tubercles was found in them. A somewhat extensive examination of specimens of chronic joint disease enables me to state that, where the synovial or other joint structures are affected with tubercles, tuberculosis of the bones also exists. This remark applies to the more advanced stages of the disease, a subject upon which we cannot enter in this lecture.

My fellow student, Charles Price, as far back as the year 1865, from his experience in excisions of the knee-joint, arrived at the conclusion that disease met with in this articulation as a rule commenced in the ends of the bones. Volkman was of opinion that strumous disease of joints commenced in the osseous tissue, and his opinion was to a great extent founded on his own observations of the early stages of joint disease. Ollier, and Gibney of New York, are of much the same opinion. Sayers has decided views as to the origin of these chronic joint cases in tuberculosis of the bones entering into the formation of the affected articulation. But we require further pathological evidence on the subject of tuberculosis of bone in the early stages of the joint disease of childhood. Such evidence as we have points to the presence of tubercular osteitis as being the starting-point of what is commonly called scrofulous joint disease. Pathologists, as a rule, further agree in considering that the outer layers of the cancellous tissue of the bone are the most frequently affected in the early stages of tuberculous osteitis. This fact, as already mentioned, is due in all probability to the marrow in this part of the bone being injured from the action of the tendons or ligaments on the osseous structure into which they are inserted. In the acetabulum the disease not infrequently begins in the attachment of the ligamentum teres to the innominate bone. In other cases, from the pressure to which the soft structures in the deep layers of the articular cartilages are exposed, they are crushed against the plate of bone upon which they rest, and so form a favourable soil for the growth of tubercles. Bearing on the pathological evidence in favour of tubercular osteitis being at the root of the chronic joint disease of childhood, we cannot overlook the fact that of all the joints of the body the spine is most frequently affected, the diseased action commencing in the cancellous structure of the bone in these cases; the same remark applies to the head of the first metatarsal bone, to the os calcis, and the astragalus. Lastly, in all advanced cases of the chronic joint disease of childhood there is ample evidence of tubercles in the affected tissues. When tubercle bacilli have found a favourable resting-place in one or other of the tissues of the medulla of bone, they speedily become surrounded with layers of cells which protect them from leucocytes or other blood scavengers. Within this nest of cells the microbe multiplies, and its offspring produce—either isolated, or, it may be, disseminated—tuberculosis of the surrounding medulla, and in the course of time the synovial and other joint structures are invaded by tubercle bacilli. Before the disease has advanced to this stage—and when it is certainly in many cases confined to the bone—is the time when the surgeon may with great advantage attack it, in the hope of destroying the microbe which has started the mischief.

We may, however, approach this subject from another point of view. Without doubt a large majority of the cases of chronic joint disease we meet with can be traced back to an injury of some kind, nevertheless in children injuries to the joints are incapable of causing chronic joint disease such as that which is seen so frequently in general hospitals throughout Europe. This is an important point, because, if it can be shown that injuries in themselves are not sufficient to cause the disease we are considering, it follows that in such cases there must be something beyond the traumatism to account for this slow but most destructive form of inflammation. Surgeons practising in all parts of India tell us they seldom if ever meet with cases of scrofulous joint disease among native children in that country. These children, however, are subject to the same kind of accidents and injuries as Europeans; they are no better fed or housed than the corresponding classes in Europe, and yet practically they are free from those chronic joint affections which are so frequently seen in our hospitals, and which from a pathological point of view we have come to think depend on tuberculosis. In this way we are led to believe that the tubercle bacillus is the something in addition to a traumatism which is necessary to produce chronic joint disease in childhood. But, it may be argued, the tubercle bacillus exists in India; why should native children, therefore, escape tuberculosis of the joints? It is true this bacillus can live and thrive in India, but tuberculosis is certainly much less common in that country than it is in Europe, and we cannot overlook the fact that hereditary tendencies form an important element in a question of this kind. Beyond this, native children in India live day and night for the greater part of the year in the open air and in bright sunshine, conditions which, as we well know, exercise a vast influence on living organic matter. Beyond this, the native child has a cold bath every day. That sunlight, fresh air, and cleanliness have an important share in preserving living tissues from the inroads of certain forms of micro-organisms is apparent for the following, among other reasons. The lower animals, such as monkeys if left in their natural condition in tropical forests, we have no reason to suppose suffer from tuberculosis; but but if these same animals are confined in close sunless cages in our zoological gardens they die off in numbers from phthisis: or take another case, the children of our upper classes suffer little from chronic joint affections in comparison with their poorer brethren living in the dark, dirty slums of our large cities. Physicians seem to recognise the importance of fresh air and sunlight in the treatment of the early stages of phthisis and other tuberculous affections. With unquestionable advantage they order such persons an open-air life on board ship during the summer and a residence in the pure atmosphere of the higher Alps in the winter. The early stages of tubercular testicle and other glands seem to be amenable to similar treatment.

From a study, therefore, of the biological relation of the marrow contained in the ends of the long bones, from its physiological functions, and from the teaching of pathology we are led to believe that chronic or scrofulous diseases of joints are due to tuberculosis commencing within the cancellous tissue of the bones. Without question such disease may and does begin at times in the deep layers of the articular cartilages; it may commence in the synovial or other soft structures surrounding a joint, but in the case of children we have no evidence to prove that such is the case, but rather the reverse. Then comes the question, Can we fix upon the site occupied by the tubercle bacillus in the early stages of joint disease? In cases of this kind there is always some tenderness over the whole of the joint, but if pressure is made with the tips of the fingers and thumb over the bones entering into the formation of the articulation we come on spots which are not only tender, but which on pressure cause the child to cry out with pain. These painful spots are permanent—if we examine them to-morrow or a

Digitized by Google

week hence there they are; and they indicate definite areas of tubercular osteitis, the commencement of the disease which at any moment may extend to the synovial or other tissues of the joint. Doubtless, in instances of hip-joint disease in its early stages, there is difficulty in ascertaining the precise position of tender areas of bone such as those referred to; the disease may commence in the acetebulum or beneath the articular cartilage of the head of the femur, but it most frequently begins in the neck of the bone, as in the two specimens already referred to, and it is because it begins in this locality, and on the distal side of the epiphysial cartilage, that bacilli often extend down the shaft of the femur, and so, after excision of the head of the bone, the disease continues in the trochanteric position and upper end of the femur. In the early stages of tubercular osteitis as before stated the symptoms are frequently referred to an accident or injury of some kind, and the patient suffers from pain and stiffness of the articulation and has difficulty in fully extending or flexing the joint without increasing the pain. On pressure over fixed points in the bones which enter into the formation of the articulation the pain is much augmented. These symptoms vary in intensity, but they persist for some weeks and are increased if an effort is made to use the limb. Within a short period the patient's sleep is disturbed at night by the spasmodic and painful movements of the limb. There may be little if any increase of the synovial fluid in the joint, but its temperature will be found higher than that of the sound limb.

The question then arises as to how we may best treat such a case, and this must depend upon the belief we hold as to the nature of the disease. If we believe, with many surgeons, that these chronic joint affections of childhood are in the majority of cases due to tubercular osteitis, then it is certain we must direct our best efforts to destroying the tubercle bacillus which has found a breeding ground in the bones entering into the formation of the diseased joint. We had in India at one time a famous general who, with reference to a more substantial but hardly less dangerous form of being than we have to deal with, was wont to say: When your enemies are in the open go straight at them, keep them moving; if entrenched, go at them until you have turned them out of their position—advice which we may with advantage apply to the case of the micro-organisms we are considering. We are, however, bound to examine the opinion of surgeons who prefer less active measures in dealing with the early stages of tubercular joint disease, and who hold that the best thing we can do in such cases is to lay the patient on his back in bed with proper extension applied to the limb until the diseased joint can be flexed and extended without pain, and, on pressure over the bones, the patient no longer suffers from pain. Treatment of this kind always takes months, and may require two or three years before complete relief from pain is secured; and even after so lengthened a period of treatment there can be no certainty that the tubercle bacillus has ceased to exist in the previously diseased bone, it may only await a favourable opportunity to recommence its most destructive influence on the tissues. Beyond this we should hardly rest content with having nothing more in the way of treatment to recommend these patients than rest in bed for twelve months—it may be two years and upwards—and that at the joyous period of childhood, a time when these little beings are overflowing with restless energy, and when constant motion seems almost necessary to a healthy development of body and mind. Nor can one help feeling, as in the case of the lower animals, that life under such unnatural conditions may predispose the individual to the attacks of various forms of micro-organisms. Further than this, surgeons in charge of our London, and of other hospitals throughout this country and the Continent, have reason to believe that in many instances rest and extension are by no means all that could be desired in the class of cases that come under their care. For instance, Mr. Howse, in his valuable paper published in the Guy's Hospital Reports for 1892, has brought together the details of 130 cases of excision of the knee-joint in children, treated by himself in Guy's and the Evelina Hospitals from 1873 to 1884. The cases are not brought down to a later date because, as Mr. Howse remarks, in a question of this kind it is all important to ascertain the result of treatment some years after the patient has been "cured," according to our most misleading hospital nomenclature. One-half of the cases of excision of the knee-joint operated upon by Mr. Howse are stated to have been treated by rest, and many of them by extensions, for upwards of two years before excision of the joint was deemed necessary to save the limb or life of the patient. The other half of Mr. Howse's patients had been under similar treatment for less than two years, and yet their condition was such that this kind of treatment had to be given up and excision of the knee-joint performed. Do what we will in cases of chronic joint disease among the poorer classes of our large cities, our efforts are in too many cases unsatisfactory, for many of these children suffer from the stain of hereditary disease which the hand of the surgeon cannot wipe away.

One of my former colleagues was at one time rather fond of excising the bones entering into the formation of the knee-joint both in the early and later stages of tubercular disease. He was not at the time in the habit of employing antiseptics and he adopted the open system of dressing wounds, no special care being taken to remove infected bone or other tissues. Nevertheless most of these patients made admirable recoveries so far as the union of the diseased bones was concerned, and the cessation of the unhealthy action in the previously affected structures. There are, however, serious objections to excision of the knee-joint in children unless necessary to save the limb or life of a patient, and under any circumstances this operation cannot be entertained as applicable to the early stages of the disease, with which we are alone concerned at present. But one could not help feeling that the favourable results noticed in the cases referred to must have been largely due to the copious flow of blood which took place at the time and subsequently to the excision of the joint; the ends of the bones and surrounding tissues were thus flushed out and their embarrassed circulation relieved, so that the natural enemies of the tubercle bacilli had an opportunity of going straight at their enemy. The subsequent drainage through the open wound doubtless materially aided the salutary action going on within the tissues. By means of the trephine, however, we may not only secure free hæmorrhage from the interior of the bone, but also make a tunnel through it which will ensure continued and efficient drainage, and further allow the introduction of an efficient germicide into the infected tissues. All this may be done at an early stage of the disease without running the slightest risk of inflicting any serious injury on the bone or soft tissues, provided that strict antiseptic precautions are followed. Having given the reasons for, and method of, operating on bones affected with acute infective osteitis, it is unnecessary to make any further observations on the subject, except that a precisely similar proceeding should be carried out in cases of tubercular osteitis in its early stages, before we have reason to think that caseation or caries of the bone has occurred. Spots in the tender bones should be exposed, and a trephine of about an inch in circumference employed so as to remove one or more small columns of inflamed bone from the affected joint. After such an operation the limb should be securely fixed to a splint, so that the dressings can be removed without disturbing the part. At the same time extension must be employed and kept up for six weeks or so, after which we may omit the extension during the day and employ massage. In another ten days the patient should be placed under an anæsthetic and complete flexion and extension of the joint carefully made; from that time gentle passive motion of the joint and massage should be employed daily, and the child, if possible, removed to the country and allowed to walk about, taking at first only gentle exercise, its amount and kind being guided by the freedom or otherwise of the patient from pain.

From considerable experience in the use of the trephine in the early stages of tubercular osteitis, I am able to state with confidence that it is possible in not a few cases to cut short disease of the knee or other joints, and so prevent it speading to accessory structures entering into the formation of the affected articulation. Treatment of this kind may without question be carried through without running any risk which may not be safely undertaken, if the alternative is either caries of the affected bones or rest for long months in bed. It seems that—as in life, so in operative surgery—we too frequently begin at the wrong end; if the experience we gain as we grow in years had been at our command at the commencement of our career it would have been better for some of us and for many of our patients. And so with surgery, all our knowledge and skill should be applied to preventing

Digitized by Google

and cutting short disease in its early stages; it is then that operative surgery may achieve its greatest triumphs. In this belief I have endeavoured to explain what seem to be the correct principles, and to deduce therefrom the line of practice to be followed in cases of acute infective osteitis in its early stages, and in the far more common and hardly less mischievous tuberculous disease of the extremities of the long bones in children.

GLEANINGS FROM SURGICAL PRACTICE.

BY THOMAS BRYANT, M.CH., F.R.C.S. ENG. & IREL.,
CONSULTING SURGEON TO GUY'S HOSPITAL; PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

III.[1]—RUPTURE OF THE SMALL INTESTINES.

RUPTURE of the small intestines is comparatively the most common form of injury of the bowels; that of the large intestine is more rare; while rupture of the mesentery with its vessels is not rarely met with. In the earlier part of this series I have recorded some examples of rupture of the small intestine which were in the first instance unassociated with any symptoms which could reasonably have suggested the probability of the presence of serious intra-abdominal mischief, and if the house surgeons who were responsible for the admission of cases into Guy's Hospital had not fully recognised the value, for diagnostic purposes, of a history of the accident, and particularly of the nature and mode of application of the force which brought it about, and from the suggestions thus acquired appreciated the possibilities, not to say probabilities, of grave intra-abdominal injury having taken place, there can be no question that serious derelictions of duty would have been reported and unhappy causes of public scandal would have arisen; for the same speedy deaths which have been reported in the cases quoted would have taken place, although they would have occurred outside, instead of inside, the walls of the hospital. All house surgeons and hospital officials should therefore be impressed with the necessity of retaining for a few hours every case of abdominal, as of cranial, injury brought to a hospital, with the sole object of watching for symptoms as a guide to treatment, particularly when the nature of the accident suggests the probability of internal mischief having taken place. I will now pass on to consider and point out what lessons are to be learned from a careful study of the nineteen cases of ruptured small intestine which are before me, for I believe some practical hints which may prove of use are to be deduced from their examination.

CASE 13. *Laceration of the jejunum from the duodenum.*—This took place in a man aged thirty-seven years who was run over, the wheel of a cart having passed over his abdomen. When admitted into Guy's Hospital there was no collapse, but the patient complained of severe pain in his abdomen and severe vomiting. These symptoms persisted for twenty-four hours, when he died. After death the two ends of the divided intestine were found to be four inches apart. The stomach was empty,[2] but the peritoneal cavity contained about three or four pints of a pink-coloured fluid, which was clearly composed of the iced water he had taken stained with blood. This case occurred some years ago. Had it happened within recent times it would, I trust, have had the benefit of some surgical help. It is to be noticed that in this case the force which produced the injury was of a dragging nature and that as a consequence the loose jejunum was torn from the fixed duodenum. Indeed, the character of the force and the mode of its application always appear to be of much value as a help to diagnosis in most cases of intestinal injury, for it would seem that where the force is of a diffused rather than of a localised character the injury is more likely to be extensive or even double. Thus, when a human being is run over, the wheel of a vehicle passing either over the abdomen or the back with the abdomen downwards; when he falls from a height upon a plank or beam; is trodden on by a horse; or is crushed between two obtuse bodies, it is most probable that either a solid viscus has been lacerated or that some portion of the small intestine has been torn in one or more places. At least this is the inference which a study and analysis of my nineteen cases yield.

In two cases the duodenum was torn—in one from a localised force, in the other from a force the exact nature of which is not recorded. In seven cases the jejunum was the seat of injury, and in ten cases the ileum. In eleven of these seventeen cases the injury was of the diffused character; in six it was more localised. In one of the eleven in which the force was of a diffused character the jejunum was torn from the duodenum, in three the upper end of the jejunum was lacerated in two distinct places, and in the fifth case the lower end of the jejunum was lacerated in one place. In four of the six cases in which laceration of the ileum was present the injury was single and situated not far from the cæcum; in one other case there were two, and in the fifth case four, separate lacerations. Thus, in four out of eleven cases produced by diffused force there were two or more seats of laceration, and this point has a practical bearing of no small importance.

In the five cases of rupture of the small intestine brought about by local forces, such as a kick from a man or horse, or a fall upon a fixed object, the bowel was ruptured in only one spot. In two of these six cases the jejunum was involved, and in four the ileum. If we take the whole number of cases together, the jejunum was lacerated in seven and the ileum in ten. In a rough sense, consequently, it may be said that the surgeon may from the history of any case and an appreciation of the probable consequences of a given injury take a sufficiently decided view as to the probabilities of the nature of the injury he has to treat as to form a provisional diagnosis, and with this in his mind wait and watch for the development of symptoms in order that he may act boldly when decision has been reached.

The following are the brief notes of the nineteen cases. Cases 6 and 7 already reported are examples of rupture of the duodenum, Case 4 of rupture of the jejunum from a kick, and Case 5 of rupture of the ileum.

CASE 14.—This is also one of rupture of the jejunum from the kick of a horse, and in reviewing these cases I feel sure that most surgeons would now admit that these cases were such as should have had the benefit of surgical treatment, and that such treatment if applied in time might in all reason have been expected to have been followed by a good result.

CASE 15. *Partial separation of the jejunum from the duodenum, with a second laceration four feet lower down from a diffused injury.*—This occurred in a man aged twenty-one years who had fallen a distance of eighteen feet across a plank upon his epigastrium. He was taken up insensible, when he vomited matter streaked with blood. When admitted into the hospital he was conscious and complained of severe pain in the region of his injury. Vomiting recurred and continued, but no more blood appeared in the vomit. He died about thirty-six hours after the accident, having experienced during the whole period severe abdominal pain and great thirst. At the necropsy there was no external evidence of injury. There was evidence of early peritonitis and in the peritoneal cavity the contents of the bowel, but no blood were found. The jejunum was partially separated from the duodenum, and four feet lower down there was a second rupture one inch long. The great omentum was slightly torn and some blood was effused into the mesentery. It is reasonable to think that surgery in this case might have saved life.

CASE 16. *Rupture of the jejunum in two places from a diffused injury.*—A boy aged thirteen years had been run over by the wheel of a van. When admitted he was partly collapsed, and marks of the wheel were seen below his right sixth rib, with bruises about the left side of the upper lumbar vertebræ. There was, however, no swelling, or direct evidence of fractured ribs, although this was suspected from the boy's jerking respiration. He complained of great thirst and brought up at once what he took. Vomiting, indeed, continued up to death. He died collapsed in about thirty-six hours. After death fæcal extravasation was found to have been present, and at the origin of the jejunum there was a rupture involving two-thirds of the circumference of the bowel, and eighteen inches lower down there was a second rupture through which the mucous membrane of the bowel bulged. It is to be noticed that in this case, as in the last, extreme thirst was a prominent symptom, and it may be added that in this case likewise surgery might have proved of value.

CASE 17. *Laceration of the jejunum in two places from a*

[1] Nos. I. and II. were published in THE LANCET of Nov. 2nd and 9th, 1895, respectively.

Digitized by Google

diffused injury.—A boy aged twelve years, having fallen from a horse, was trodden upon by the animal's hind leg on his abdomen. He was but little collapsed after the injury, and vomited, but not blood. He complained of great pain in his abdomen. He also passed bloodless urine. The pain and vomiting continued for two days, and by some error a dose of castor oil was given. Three hours later the abdomen began to enlarge, and in six hours the bowels acted, the motion being natural in colour and free from blood. On the fourth day abdominal pain was severe, great thirst also appeared, and vomiting returned. The abdomen also became tympanitic. In fact, acute peritonitis appeared, which ended life on the sixth day. At the necropsy no trace of bruising was to be seen. The abdomen was distended, and on opening it universal peritonitis had evidently existed, and air bubbled up upon separating the coils of intestine. *At two spots* in the jejunum, one about fourteen inches below the pylorus and the second a foot lower down, were two apertures. One appeared as a circular hole a quarter of an inch across; the other was more oval, with its long axis placed transversely and nearly an inch in length. The right pleura where in contact with the diaphragm had a layer of lymph upon it. There was little or no evidence of fæcal extravasation beyond the presence of bubbles of wind when the abdomen was opened. This is somewhat remarkable, as it might have been presumed that the dose of castor oil which was given on the third day would have of necessity caused fæcal extravasation instead of a good action of the bowels unassociated with the passage of blood. It may fairly be added that in this case surgical interference could have been useful, and in these days would have been applied.

CASE 18. *Rupture of the ileum in two places from a diffused injury.*—A girl aged thirteen years, having been thrown out of a cart on to her face, was run over the back obliquely by the two side wheels of a passing dray. She was admitted with a graze on the right loin and great local swelling from effused blood, and much collapsed. She vomited as the collapse became less marked, but only the contents of the stomach (no blood). The next day the lumbar swelling had lessened, but the abdomen had swollen and become painful on pressure. She sank thirty-six hours after the accident. After death fæcal extravasation was found in the peritoneal cavity from two separate lacerations into the ileum. In this case an operation would probably have saved life. Indeed, in all the four cases which have just been recorded the same observation is applicable, although in each of them there were two distinct seats of laceration. In all the four cases it should likewise be noted that the force which produced the injuries was a diffused one. The same observation as to the nature of the force applies to the case I am about to relate, but not as to the question of surgical interference, for in it—although the four ruptures might have been remediable under surgical guidance—death took place too rapidly from hæmorrhage to allow of such a hope to be entertained. Had this complication not existed surgical help might have proved applicable and successful.

CASE 19. *Abdominal injury from the passage of a cart wheel; four lacerations of the small intestine found after death, with fracture of the pelvis.*—These injuries occurred in a man who was admitted into Guy's Hospital in a dying condition. At the necropsy the external signs of injury were small. Blood in large quantities was found in the peritoneal cavity which came from a torn mesenteric vein. The small intestine at about its centre was divided, the two ends lying loose in the cavity;[3] near the upper one there was a partial severance of the bowel, and below the lower end were two smaller lacerations, making four in all. The pelvic bones were broken, but the bladder was intact.

I will now pass on to consider cases of ruptured intestine in which one seat of rupture alone was found, and it will be of interest to note that whereas in four of these cases the injury was of a diffused nature, in five it was more of a local character—in four from a kick by a horse and in one by a man.

CASE 20. *Ruptured jejunum from a diffused force.*—A woman aged fifty-two years was admitted after she had been run over by a cart wheel which passed over her abdomen. When seen there were no external indications of injury and no very serious signs of collapse. There was, however, pain in the region of the umbilicus, which increased, and she vomited twice. Prostration, however, followed, and death occurred on the second day. After death the only injury was a rupture about half through the [illegible] a half from the duodenum. There was a little local [illegible] vasation, with evidence of early peritonitis.

CASE 21. *Rupture of the jejunum from a* [illegible] occurred in the case of a man aged twenty-five years [illegible] having been kicked below the left lower ribs by a horse, [illegible] brought to the hospital in a cab, he having vomited [illegible] road. He, however, walked into the hospital. When [illegible] in bed he vomited and was somewhat collapsed. He [illegible] plained also of severe abdominal pain. Nothing [illegible] could be made out. He subsequently had suppression [illegible] urine, and died thirty-six hours after the accident. At the post-mortem examination some slight abrasion was [illegible] over the left crest of the ilium. There was evidence of [illegible] peritonitis, and in the free edge of the jejunum, about [illegible] feet from the duodenum, there was a rupture through [illegible] its circumference, through which the mucous mem[illegible] protruded, showing everted edges.

CASE 22. *Rupture of the ileum from a local* [illegible] female child aged four years was admitted after having received a kick in the abdomen which was quickly followed by vomiting, severe abdominal pain, collapse, and death in fourteen hours. After death a lacerated wound of the integuments of the abdomen was seen to be present below the umbilicus, more towards the left side, and on opening the abdomen fæcal extravasation was found to have existed. Immediately behind the abdominal wound a coil of ileum six feet from the cæcum was found ruptured transversely nearly throughout its circumference, and the wound was gaping widely. No surgeon could have looked at the specimen without a regret that his art had not been applied to the case for its relief.

CASE 23. *Rupture of the ileum from the kick of a horse.*—A man aged forty years was admitted after the receipt of injury to his left groin, with slight collapse, but much swelling above Poupart's ligament from effused blood and intense local abdominal pain. He could not bear to have his legs extended. He had been sick after the accident. His urine was clear when drawn off, and he subsequently passed it naturally. He also passed flatus downwards. He died within forty-eight hours of the accident, vomiting and pain having persisted. After death a perforation of about the middle of the ileum was found, with but little fæcal extravasation and peritonitis as a result. This case occurred in 1877, and I then added to my notes of the case my regret that I had not operated upon the patient.

CASE 24. *Rupture of the ileum from the kick of a horse.*—This case is that of a man aged forty-one years who was admitted collapsed and in great pain one hour after the accident. There were no external signs of injury. He had vomited several times before admission and had passed urine. The same day he vomited again, and his bowels acted naturally. Vomiting at intervals took place during the second and third days, and his abdomen became more distended. On the third day he passed flatus downwards with relief, and he had a large action of the bowels. His powers were, however, clearly failing, and he died on the fourth day. After death much pus and fæcal matter were found mixed together in the abdominal cavity, and the small intestine was completely ruptured about three feet from the cæcum with its mesentery. This case was clearly one which should have been operated upon. The local injury was the only cause of death and could have been repaired.

CASE 25. *Rupture of the ileum from a local injury; death on the sixteenth day.*—This occurred in a boy aged [illegible] years who was brought to Guy's Hospital about [illegible] hours after having received an abdominal injury through falling upon a curbstone with other boys upon him. The accident was followed by neither sickness nor collapse, but by intense abdominal pain, and it was because the pain continued and the boy's abdomen began to enlarge that he was brought to the hospital. When admitted he clearly had peritonitis, from which he died on the sixteenth day. After death a large fæcal abscess was found in the right side of the abdominal cavity, which extended from the right iliac fossa to the liver. Near the cæcum a coil of small intestine was found to be perforated by a hole [illegible] which was round and had [illegible] membrane. The case was [illegible] ference, which should [illegible]

CASE [illegible]

[illegible] Museum, Guy's Hospital Museum, 1877, No. [illegible] admitted into Guy's [illegible]

Digitized by Google

complaining of great pain and abdominal tenderness. He had vomited before his admission, but no blood. On the second day his bowels acted naturally, and his general condition was so satisfactory that it was hoped that no internal mischief had taken place. His abdomen, however, gradually became more distended and his powers failed, so that he died on the eighteenth day. At the necropsy fæcal matter escaped from the abdominal cavity as soon as it was opened, and a coil of small intestine which proved to be ileum near the cæcum was extensively lacerated and adherent to the parietes. It is to be noticed that in this case the symptoms were very insidious. The action of the bowels on two occasions during its progress is a point to remember, for such an action is quite consistent, as already demonstrated, with intestinal ruptures. In this case, as in so many of the former, it is to be regretted that more active surgical treatment had not been carried out.

CASE 27. *Ruptured ileum near cæcum from a diffused force; death in seventy-two hours.*—A railway porter aged twenty-eight years was admitted under my care in March, 1877, having been knocked down by a train. As a result of this accident he received a severe wound at the back of his head, exposing bone, and contusions about his thorax and abdomen. When admitted he was in a state of severe collapse, and he remained in this condition for about twelve hours. During this time he had his bladder emptied by means of a catheter, and his urine was normal. As he rallied from his collapse he became somewhat delirious. Twelve hours after the accident he vomited, and the vomit contained much blood; later also blood came up in small quantities. The day after the accident there were some distension and tenderness of the abdomen, especially in the left iliac fossa and lumbar region, and the vomiting became fæcal. The man sank seventy-two hours after his admission. At the necropsy there was evidence that peritonitis had been present, and a rupture of the small intestine was found to the extent of an inch about ten feet above the cæcum. There was very little fæcal extravasation into the peritoneal cavity, and what was present was localised by firm adhesions of the surrounding parts. In this case surgery could have done much, and an exploratory operation should have been made when the abdomen became distended.

CASE 28. *Rupture of the ileum from a railway injury.*—A man aged twenty-eight years was admitted, collapsed and vomiting, with a scalp wound and some injury to his head as well as to his abdomen. He died sixty-five hours after the accident, and the case was never clearly diagnosed. At the necropsy general peritonitis was found, and the effused lymph was bile-stained. On separating the matted coils of intestine a rupture half an inch long was found in the upper part of the ileum on its convex side, the opening being sealed by recent adhesions. Extravasation only took place when the coils were separated.

Remarks.—It is to be hoped that a careful study of the cases, which have just been briefly reported, will not only prove of interest but of some practical value; for it may be stated that these notes have been collected during a period of a quarter of a century ending with the year 1888, when I was working at Guy's Hospital. When writing my notes year by year in the past it was my general custom to append some remarks to each important case as to the treatment which might have proved successful, and particularly with reference to laparotomy, and it has to me been a curious fact that to almost all of the seventeen cases I have recorded a note was appended to each as it was taken that the case was one for which surgical interference might have been expected to have been successful. I regard this incident as one worthy of record; for it forms a very strong argument in favour of a surgical exploration in cases in which clinical evidence is scanty as well as in cases in which it is fairly definite. I can only add that had I had before me in past years the evidence I have now the pleasure of presenting to my surgical brethren, I should have performed laparotomy in many cases of abdominal injury which I then passed over much to my present sorrow, and, I fear, to the loss of lives which I might have saved. Before considering the treatment of these cases of abdominal injury as a whole I should like to place on record some exceptional examples. Case 29 was one of rupture of the mesentery in which there was not only hæmorrhage from venous laceration which led to death, but symptoms of obstruction to the venous circulation of certain coils of small intestine brought about by their passage through the rents in the mesentery. Case 30 was one of rupture of the lung caused by the wheel of a cart, when in contact with a child's abdomen and lower ribs, pushing the body along a road. Case 31 was an example of rupture of the septum ventriculorum of the heart from external injury, in which the patient survived twenty-one days. I would also like to illustrate the fact that secondary changes may take place in injured abdominal tissues which may not only in some cases lead to death, but in others give rise to subsequent affections which may call for help.

CASE 29. *Rupture of the mesentery with its veins, complicated with partial strangulation of the bowel, hæmorrhage, and fracture of the pelvis.*—This case was that of a man aged thirty-three years who was admitted into Guy's Hospital after having had the two side wheels of a loaded van pass over his abdomen. Collapse and vomiting immediately followed the accident and persisted till death occurred forty-eight hours later. At the necropsy the abdominal cavity was found to contain several pints of liquid blood; the surface of the small intestine was in patches ecchymosed, and some of its coils were of a dark, congested colour. In the mesentery near its attachment to the intestine there were three separate rents through which coils of intestine had passed, and these coils were much congested, although not strangulated, but the venous circulation through the coils had been clearly much interfered with. There was no rupture of the intestine, but there was a fracture of the crest of the ilium. The patient died probably from hæmorrhage due to rupture of the mesentery with its veins, although the fatal result was probably helped by the persistent vomiting which continued to the end of the patient's life, and which was caused and kept up by the herniation of the coils of small intestine through the rents in the mesentery. It is very probable that in this case life might have been saved by an operation.

CASE 30. *Rupture of the lung without fracture of the ribs.*—A boy aged seven years was knocked down by the shaft of a cart and then pushed along by one of its wheels pressing against the left side of his abdomen. The wheel did not pass over his body. The child was admitted into Guy's Hospital in October, 1858, in great pain, and when placed in bed at once rolled over on to his abdomen on the right side, with his left leg drawn up. He also coughed up blood. He soon became unconscious and died. At the necropsy there were no external visible signs of injury except a small bruise on the left side of his back. There was no fracture of any rib, but the right side of the chest was full of air and contained several ounces of blood which came from a laceration of the lower edge of the middle lobe of the right lung. There was also a laceration of the anterior border of the liver and of the left suprarenal capsule.

CASE 31. *Rupture of the ventricular septum of the heart, with contusion of the abdomen from the passage of the two side wheels of a heavy van over the lower part of the chest and upper part of the abdomen; death on the twenty-first day.*—This happened to a boy aged eight years who was admitted into Guy's Hospital under my care on July 15th, 1885. He was brought direct to the hospital after the injury and was admitted in a very collapsed condition. At that time his pulse was 136 and there was a marked thrill over the cardiac region, with a roaring to-and-fro bruit. He vomited several times after admission. His urine was passed naturally. Dr. F. Taylor saw the child with me and diagnosed a communication between the two ventricles of the heart. On the fifth day the child had decidedly improved. His bowels had acted naturally and he took liquid food well. On the fifteenth day the report says that the abdomen was natural, but the bruit was louder than it was when the boy was admitted. Pulse 130, irregular, intermittent, and occasionally imperceptible. Temperature in axilla was 95°F., and in the rectum 98°. On the nineteenth day symptoms of pneumonia appeared, from which he died on the twenty-first day. After death the rupture of the septum ventriculorum was found, with evidence of pneumonia of the left lung and base of the right. No ribs were broken, and there was no evidence of any other lesion.

CASES ILLUSTRATING THE SECONDARY EFFECTS OF ABDOMINAL INJURY.

CASE 32. *Contusion of the stomach and duodenum following a diffused abdominal injury, followed as a secondary consequence by perforation of the duodenum by ulceration, leading to peritonitis, and death on the nineteenth day.*—A boy aged eight years was admitted into Guy's Hospital on June 16th, 1884, under my care, after the passage of the two side wheels

Digitized by Google

of a loaded van over his abdomen. He was collapsed at the time, but was conscious. He also vomited, bringing up some blood mixed with the vomit; a few hours later he vomited again, about an ounce of red blood. He passed his urine, which was healthy. He was ordered to be fed by nutrient enemata, and given a teaspoonful of milk occasionally. For some days the patient was restless and complained of abdominal pain, which was always increased after taking the small quantity of milk which was allowed. On the eighth day the bowels acted; on the tenth day the abdomen became distended; on the fifteenth day he vomited again, a little brown fluid which gave the reaction of blood, and this vomiting continued daily until he sank on the nineteenth day. At the necropsy an ulcer was found in the posterior wall of the stomach, as also in the duodenum, where apparently these parts had been pressed against the bodies of the vertebræ by the passage of the cart wheels. The ulcer in the duodenum had perforated, and as a consequence an abscess existed in the lower cavity of the omentum, in which some milk lately taken was found. Local peritonitis existed about the injured parts. This case was clearly one of bruising of the stomach and duodenum, followed in the latter part by ulceration, which led to death. It would have been better if, in this case, life had been maintained by nutrient enemata and that the stomach had been simply washed with medicated water such as water and boric acid in small doses. To have given milk was a mistake, as such a food called upon the stomach for work for which it was incompetent. It is a question whether any operation to repair the duodenal ulcer would have been of value; as a primary line of treatment it would have been uncalled for and useless.

CASE 33. *Injury of the intestine from a local force, followed by sloughing of the injured tissue and death on the fifth day.*—A trooper in the 1st Life Guards aged twenty years, when taking his horse to drink at 5 P.M. on May 8th, 1888, received a kick from a horse on his abdomen, and felt the full force of the kick in his right iliac region. He was at once taken to the military hospital near Regent's-park and seen by the surgeon in charge, Mr. F. Hume-Spry. His face was then pale and his pulse feeble, and he complained of great pain in the seat of the injury, where there was a bruise three and a half inches by three-quarters of an inch. Hot fomentations were ordered and from these he felt relief, so that next morning he was better, although the abdominal muscles were probably more tense. Opium was also given and a tablespoonful of milk every two hours; vomiting, however, continued during the day and the abdomen enlarged. The second day the local symptoms were unchanged, vomiting had lessened, and he asked for food. On the third morning tympanites was less, but vomiting returned, so that all food by the mouth was stopped and he was ordered to be fed entirely by the rectum. On the fourth day he was decidedly better in all ways and looked better. Vomiting had ceased and pain had lessened. On the fifth morning a sudden and great change had taken place, for he was found clammy and collapsed, and he died at 2.30 P.M. At the necropsy fluid somewhat resembling pea-soup escaped in abundance on opening the abdomen, and the intestines were glued together by lymph. In the ileum, about four inches above the cæcum, some four feet of bowel were congested and bruised. At two places there were sloughs, and from one of these the fæcal extravasation had taken place. In this case it is fair to assume that the bowel as a direct result of the injury was only bruised and not ruptured, although it is quite possible that one or more of the inner coats of the intestine might have been torn. At any rate, it seems probable that it was from the injured parts not undergoing repair, but sloughing and ulcerating, that the secondary effects of the injury took place, and that death occurred.

CASE 34. *Abdominal injury followed for two weeks by the passage of blood with the motions, and subsequent attacks of abdominal pain and diarrhœa after exertion for the subsequent three years.*—A man aged twenty-seven years had, three years before I saw him, received a severe abdominal blow from a fall from a tall bicycle. The accident was followed by collapse and the passage of blood with his motions for a period of two weeks, the motions at times being very loose. He subsequently convalesced, but he had ever since the accident been the subject of severe abdominal pains associated with more or less sickness and diarrhœa after anything like severe exertion. I saw the patient in 1893, and was disposed to think that at the time of the accident some injury was caused to the lining membrane of the colon—probably some laceration—and that as a result of this when exhausted by exertion his attacks of pain &c. were due. At any rate, by acting on this view and limiting exertion and regulating diet, these attacks soon gradually ceased, and a year later he seemed to be well.

A CASE OF MICROCEPHALUS FOR WHICH LINEAR CRANIECTOMY WAS DONE BY TWO STAGES.

DEATH AFTER THE SECOND OPERATION, AT WHICH A LARGE SUBDURAL HÆMATOMA WAS FOUND EXCAVATING THE LEFT HEMISPHERE.

BY JAMES SHAW, M.D., D.P.H. GLASG.,
AND
WALTER C. DENDY, F.R.C.S. ENG.

THE following case of microcephalus for which linear craniectomy (so-called) was done, without, however, achieving its object, may be thought worthy of being added to the already large volume of literature on the subject, partly because the matter is still under discussion, and partly because every operation of this kind ought to be honestly submitted to criticism, especially when death follows soon afterwards. Only by the most rigorous straightforwardness in recording failures can the successful cases be of the least use to those who make the final judgment on such questions; and we therefore feel bound at least to offer the narrative of this example, leaving it to others to decide whether or not the importance of the matter warrants the publication of these notes. An introductory essay on craniectomy and microcephalic idiocy would involve a discussion of conflicting views of the pathology of microcephalus, an analysis of recorded cases, and a historical retrospect, all of these subjects being extremely interesting; but the space which would be necessary for so much detail is quite beyond the needs of a communication which aims only at the narration of a case and the affording of material for each to make his own comments upon. But those who undertake these operations must at least leave no effort unattempted to justify the acceptance of a grave responsibility, and therefore it may be pardonable if a few prefatory remarks are made on certain practical points which are helpful in dealing with some of the risks and dangers incidental to the operation now under consideration. The recorded cases show that the causes of death after craniectomy are shock, hyperpyrexia, and possibly meningitis; but the latter would appear to be only a possibility, there being seldom time for the development of inflammatory sequelæ, death when it does occur being very rapid in its onset. The two causes, therefore, of strictly practical importance are, in the order of frequency, shock and hyperpyrexia. Shock seems almost invariably attributable to hæmorrhage, and therefore it is necessary to bear in mind the sources of bleeding in these cases and thus to be prepared to deal with it promptly, by prevention if possible, and if unavoidable to check it effectually. Hæmorrhage may occur from (1) the scalp; (2) the diploe; and (3) the meningeal vessels, chiefly, of course, the middle meningeal artery. Hæmorrhage from the scalp may be almost entirely avoided by one of two methods—(*a*) by encircling the head with Esmarch's tube moderately tightly applied; and (*b*) by inserting a cordon, so to speak, of sutures round the periphery of the flap by means of strong silk stitches about three-quarters of an inch long. This method is described and adopted by Dr. Lanphear of Kansas City.[1] In the present case the first plan was used and entirely succeeded, no ligatures being needed at all. Bleeding from the diploe does not appear to have given trouble in the recorded cases, and probably this is due to the fact that the bones are often very thin and contain little diploic tissue, as was the case in the present example. The same may be said of the meningeal vessels. No trouble occurred from this source in our case, and apparently with great care it may almost always be avoided; but a branch of the middle meningeal may be injured accidentally, as occurred in Dr. Lanphear's case.[2] He dealt with this by means of a

[1] See International Clinics, Third Series, vol. ii., p. 227.
[2] Loc. cit. supra.

Digitized by Google

"needle armed with fine juniper oil catgut inserted through the dura, carried under the vessels, brought out a line or more away from the artery and the gut tied, thus ligating *en masse*."[3] Additional measures for avoidance of shock consist in administering before operation an enema containing a drachm or two of whisky or brandy, resting the head on a hot-water rubber cushion, and bandaging the lower limbs and body in cotton wool. In the event of subdural collections of fluid, blood or otherwise, a small opening is necessary to allow slow escape, lest too sudden and rapid a lowering of pressure should induce fatal collapse.

Hyperpyrexia following craniectomy has been the cause of death in several recorded cases, notably one of Mr. Horsley's, which was, in fact, one of the first two cases operated on by him, and reported in his address at the meeting of the British Medical Association in 1891. He considered the hyperpyrexia to be the consequence of injury to the thermotaxic or heat-regulating centres in the cortex, and this conclusion is corroborated, not only by the phenomenon of increased heat of a paralysed limb in injury to the motor area, but also by an interesting case operated on by Dr. Lanphear and reported in the volume of the International Clinics above quoted. In this instance the temperature rose suddenly after operation, and this was found to be the result of the accidental slipping in of a rubber drainage-tube which lay under the bone and pressed on the motor area. On the removal of this the temperature at once fell to normal. The risk from this quarter, therefore, will be reduced by avoidance of interference with the cortex, and care should be taken to preserve the dura mater from injury unless puncture or incision be rendered necessary by the presence of subdural fluid acting as a compressing agent on the subjacent brain. Recent expressions of opinion appear to be in favour of a continued trial of the operative measures, which are essentially one and the same in object, however much the details may vary—that is to say, which aim at the relief of pressure on the brain and at affording a substitute for the natural means of progressive expansion, which are normally supplied by the sutures and fontanelles, whose abnormal closure in such cases as are suitable for this treatment has made such substitution desirable. Whether linear craniectomy, or, more strictly, craniotomy, will give place to simple trephining, consisting in the removal at intervals of a series of discs, or whether the two methods may be combined by chipping out with forceps the strip of bone joining two trephine apertures, it seems to be clear that the last word has not yet been said on the subject, and that although some authorities have decidedly expressed a condemnation of the operative treatment of idiocy, yet a balance of opinion leans to the view that there exists a class of cases where the indications seem to require some procedure which will remove an injurious degree of intra-cranial pressure, whatever the exact causal relation may be between the cranial and cerebral defect in development. And we felt justified, even in the absence of any definite localised signs of brain lesion such as convulsions or paralysis, in giving the patient a chance of relief, because there existed a very obvious condition of microcephalic deformity, a marked stunting of the frontal region, and decided ridging along the lines of the coronal and sagittal sutures, with synostosis of the latter and obliteration of the fontanelles. The history of the pregnancy preceding the birth of the patient contains two very severe attacks of abdominal pain, severe enough to cause the mother to fear that she was about to miscarry. These threatened abortions (as she believed) occurred on Jan. 2nd, 1894, and in the following month (Feb. 12th), and from the first date up to the labour she said she was never long free from more or less abdominal pain. Assuming the accuracy of this history, there is evidence of intra-uterine disturbance, which might have been an important factor in bringing about meningeal hæmorrhage, and thus accounting for the large subdural blood collection which existed on the left side of the head, as will be seen in the following narrative.

The patient was a boy aged between eleven and twelve months, and was born on April 9th, 1894. The complaint of the parents on seeking advice was on account of the following:—(1) the deformity of the head; (2) the indifference of the child to its surroundings, the usual response made by ordinary children (called popularly "taking notice") being absent; (3) inability to sit up; (4) frequent fits of crying, sometimes lasting all night long; (5) coldness and blueness of the hands; and (6) tight clenching of the hands—the thumbs being drawn in across the palms, so that his hands could only be opened with difficulty. The child's parents agree that this was more marked on one side than on the other, but they differ as to which side. The child's health in other respects had been good, and his nutrition generally unimpaired. The child was born after natural labour at term. The mother was walking in an orchard on April 8th, 1894, and at 6 P.M. was suddenly aware of a gush of "water" from the vagina. From this point her labour progressed until the birth of the patient shortly after midnight (April 9th, 1894). No instrumental aid was needed. She says the "pains" were not felt for some time, but when they did come on they were "bad." She felt the head descend at each "pain," "going in" again between them. Dr. Shaw conducted the labour, and the following facts as to the child's head were observed by him. There was a marked "caput succedaneum," and the distortion of the head was very obvious at first sight. Viewed from before the forehead presented a triangular outline rising above to a sharp peak. All along the lines of the sutures the edges of the bones overlapped, giving rise to a prominent ridge, which gave a feeling like that of the edge of a book when the finger was run along the sutures. The ridge corresponding to the mid-frontal suture was most prominent. The triangular frontal bone could be moved very easily over the front borders of the parietals, and was also movable from side to side. The occipital bone overlapped in a similar manner at the lambdoid suture. The right parietal at the sagittal suture rode over the left, this being increased by lateral compression of the head. The two fontanelles at the vertex were inconspicuous at birth. When the child was seen six months later no trace of the fontanelles existed, and the sutures were firmly ossified and still marked by prominent ridges. The face was very large relatively to the cranium. No teeth have as yet appeared. On Feb. 23rd, 1895, the parents were anxious that the chance afforded by operation should be given, and were willing to take the risks, which were fully explained to them, that the child might not survive operation, and if it did that no benefit might result. The patient was well grown and in good general health. The head was a conspicuous example of microcephalus, the measurements being as follows: circumference at the level of the eyebrows, 15½ in.; transverse diameter at situation of pterion (at the middle of the latter), 2⅞ in.; transverse diameter through a point just in front of each meatus, 4 in. The forehead was peaked, the whole frontal region of the skull was narrow, and the face excessive in development relatively to the cranium, the normal ratio being reversed. The whole upper part of the skull was stunted, giving the idea of an average base fitted with a vault much too small for it. The occiput was small, but less disproportionate than the frontal end. When viewed from above the general features and the relative size of the frontal half of the skull above described were well seen. The sides converged sharply, allowing much more of the various parts of the face to be seen than can be done in ordinary heads of children of the same age. On each side at the region of the pterion there was a depression as if the temples had been compressed at this point, which gave the minimum transverse measurement (2⅞ in.). With regard to the nervous system, except the spastic contraction of the fingers and adduction of the thumbs across the palms, there were no abnormal signs definitely localised. Paralysis, convulsions, twitchings, and strabismus were absent; no monoplegia existed. The knee reflexes were present, but there was no ankle-clonus. The child seemed to manifest a general muscular-weakness in respect of not being able to sit up, but in resistance to interference he showed considerable power. Lethargy was very noticeable, and there were no signs of the perpetual movements which healthy children when awake and not feeding usually delight in. No trophic changes in the muscles were observed. The patient did not start when sudden loud sounds were made or when a bright flash of light was thrown on his face. All signs of pain or cranial tenderness were absent. Neither signs of pleasure nor of distress were evinced, except the latter when he was actually inconvenienced by attempts to measure or examine. With regard to sight, the absence of response to a bright light flashed on his eyes indicated impaired vision, if not blindness. The optic discs were very white, and the vessels of the fundus appeared small. There was no orbicularis spasm during ophthalmoscopic examination. The expression of the

[3] Loc. cit.

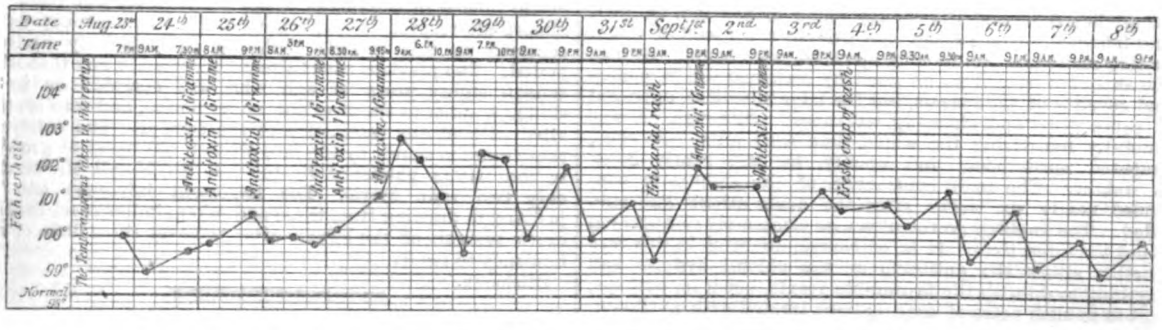
Digitized by Google

face was vacant. As to hearing, there was little evidence either way. His mother said he took the breast eagerly and knew when his meals were due.

First operation, on the right side, on Feb. 23rd, 1895.—The usual preparation of the head by shaving and thorough cleaning was done, the former over-night and the latter some time before operation. Chloroform was administered by Dr. Shaw. Esmarch's tube was applied moderately tight around the head, and effectually prevented any hæmorrhage. A flap of scalp was raised and turned outwards by an incision on the right of and parallel with the median sagittal line, joined at each end by curved ones, all taken down to the bone, so that the whole of the soft structures were reflected from the bone. The length of the median incision was about three inches, extending from the anterior hair line to a point near the parietal eminence. A disc of bone was cut out with a ½-in. conical trephine of modern aseptic construction. This aperture was made at the hinder end of the exposed area, and the dura mater was seen to have no pulsation; it bulged very little and gave no distinct sense of elastic resistance. No puncture was therefore made. A strip of bone about half an inch wide was quickly removed by means of Keen's forceps, the gap so made extending a little further forward than the skin incision. A further area of bone was similarly chipped away downwards and outwards from the front end of the first cleft to give additional room for expansion at the part where the greatest narrowing existed. The flap was replaced after irrigating the whole wound with sterilised water and drying carefully. Silk sutures were inserted all round except behind, where the edges were maintained in accurate contact by the fixation of the rest, and this opportunity was taken to allow for any tension which might be caused by sero-sanguineous exudation. Antiseptic dressings were applied as usual. The operation lasted thirty-five minutes, not counting the dressings, and no shock was caused. After about a week of apyrexia the wound was soundly healed, no pus having been produced.

Second operation, on the left side.—On the 29th of the following month (March, 1895) the left side was similarly operated on. No fresh description is needed of the steps of the operation; however, on exposing the dura mater no pulsation was visible, but the membrane bulged into the trephine aperture in a very marked degree. In spite of care, the trephine pin dinted the dura mater, but did not actually wound it. The elastic resistance to the finger was so pronounced that there seemed to be no doubt of fluid beneath. A small puncture was therefore made with the scalpel, which was immediately followed by a jet of blood, which shot out as if under considerable pressure; this continued for some moments, to the amount of two or three ounces, according to guess, gradually subsiding till only a trickling stream remained. The small slit was next cautiously enlarged to enable the forefinger to be inserted, which resulted in finding a large cavity, into which the whole length of the finger could enter. This cavity seemed to have excavated so large a part of the hemisphere that the back and front regions could only be partly felt and seen, the greater part of the left side of the cranial cavity being taken up by the huge blood cyst, the lining of which was deep red in colour with adherent clot. The fluid blood which escaped was neither so bright as arterial nor so dark as venous blood, and was less clear and bright than freshly shed blood. It was quite odourless. The condition of the child became so bad from collapse, in spite of care taken to allow the cavity to be very slowly emptied, that the cyst was quickly packed with gauze and the flap of scalp replaced and kept in position by two or three silk sutures, ordinary gauze and wool dressings being applied as usual. Meanwhile, the child had had a rectal stimulant injection and copious warmth to the surface, as well as having his lower limbs wrapped in wool. The shock was partly rallied from, but in five hours' time from being removed from the table the child died, no convulsions having occurred, but more or less shock persisting. Most unfortunately no persuasion succeeded in obtaining permission to make a necropsy, and the condition of the opposite hemisphere can therefore be only inferred.

Remarks.—The absence of a necropsy unfortunately makes it difficult to say whether this case can strictly be regarded as one of porencephalon, and no proof was obtained of any similar condition on the right side of the head. One suggestion arising from this case is perhaps that in all cases the left side should be first dealt with, on the ground that the speech centre is situated on this side; this rule had been followed an unnecessary operation the other side would most probably have been avoided. appearances found at the second operation, together the history of the pregnancy and the probable period of intra-uterine compression of the head, suggest probability of meningeal hæmorrhage, leading to development as a primary condition resulting in synostosis and closure of the fontanelles. Whatever the precise pathology may have been, it is certain that during life there nothing to reveal the exact lesion, although it would appear that the fact of marked ridging along the lines of suture may be taken, in absence of localised evidence, as indication for operating. (It may be added that after first operation the mother believed that the patient brighter and less restless, with fewer attacks of cyanosis unfortunately we failed to see the evidence of this desired change.)



A CASE OF TRAUMATIC TETANUS TREATED WITH TETANUS ANTITOXIN AND CHLORAL HYDRATE.

BY REGINALD HARTLEY, M.D. DURH.,
HON. MEDICAL OFFICER TO THE LAMBERT MEMORIAL HOSPITAL, TIS

A MAN aged forty-four years, 5 ft. 11 in. in height, 12 st. 6 lb. in weight, married, whose wife and children were living, was shoeing a horse in a forge on the morning of Aug. 9th, 1895, when the animal kicked and knocked him down. He fell on his right side, bruising his right elbow and wounding the forearm near the elbow with a nail which was projecting from a horseshoe lying on the floor of his shop. When he got up the horseshoe was hanging to his arm, and a smart tug had to be given to get it out. The pain was considerable, but disappeared in an hour or two. In the afternoon the elbow swelled and got stiff, so he came down to the surgery, where at 4 P.M. he saw Dr. A. C. Ferguson. The wound was carefully washed with sublimate lotion and dressed with iodoform ointment. On Aug. 12th and 13th he again came down for attention; on the latter day the wound was found to be completely healed, but there was a small lump on the ulna, where the nail had penetrated. On Friday, Aug. 23rd, at 7 P.M., he came again, as he did not feel well. He said that on the previous morning he had found that he could not swallow well, especially solids. On taking a long breath he felt acute pain darting from the right forearm into the neck. He had had very little sleep during the night because of the pain. He had had three separate attacks of spasm in the right arm. On the morning of Aug. 23rd he still had difficulty in swallowing, but no spasm of the arm until 2 P.M. A third spasm occurred at 4 P.M. and a third at 6.30 P.M. At 7 P.M., when he was seen in the surgery, he had a severe attack of spasm, involving the whole of the right arm and fingers. The mouth could not be opened widely, as the jaws were stiff. There was a tender swelling on the ulna, about the size of a sixpenny-piece, where the nail had penetrated. The seriousness of his case having been explained to him, he consented to go into the hospital, where he went straight to bed after a hot bath. He had a cup of cocoa and milk and drank it well. At 8.55 P.M. he had a short spasm of the right arm. At 9 P.M. 40 gr. of chloral hydrate were given, and he fell asleep an hour later. He slept until 1.30 A.M., when he awoke with spasm in the left arm. He then slept on uneasily from 3.30 to 7.30 A.M. Since his admission he had taken, as ordered, 4 oz. of milk and one tablespoonful of prepared meat juice every four hours. At 8 A.M. he had a raw egg beaten up with half an ounce of brandy. He was visited at 9 A.M., when he expressed himself as comfortable. He was again visited at 1 P.M., when he had had a short sleep. On visiting him again at 7.30 P.M. he had had three spasms, each more severe than the last. One gramme of tetanus antitoxin, procured from the British Institute of Preventive Medicine, was injected. At 10 P.M. he was half asleep. The pulse was steady. He had restless, troubled sleep, with moaning at intervals until 1 A.M., when he was awakened with great pain and spasms in the right arm, left hip, and across the back

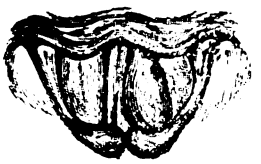
Digitized by Google

Forty grains of chloral hydrate were given. He slept until 6 A.M., when he was awakened by spasms over the hips and loins and felt a constant tendency to grin. There were also painful spasms in the left arm. On being visited at 9 A.M. the grin was at once noticed. He was unable to open his mouth more than a quarter of an inch. One gramme of antitoxin was injected. On visiting him at 1 P.M. the patient was found to have had a quiet morning. By 5.30 P.M. he had had many short sleeps. The muscles were less forcibly contracted and the pain was less severe. At 9 P.M. he was comfortable on the whole and drowsy. The right arm was more frequently affected by spasm, but in a milder form. One gramme of antitoxin was injected. The patient thought he could swallow with less difficulty. He fell asleep at 9.30 P.M. and rested quietly until 12.30 A.M., when painful spasms came on, with great restlessness. Forty grains of chloral hydrate were given by the nurse, after which he tossed about and had intervals of troubled sleep until 7.30 A.M. On the 26th he was quite clear in his head. The right arm was in a state of strong tonic rigidity. The lips felt less "tight and tied up." At 3 P.M. he had had a comfortable day. As the bowels had not acted an enema was ordered, with a satisfactory result. At 7 P.M. he had had no sleep. The lips felt more stiff, and he did not swallow so well. The jaws were more contracted. Pain was severe when he breathed. At 9.15 P.M. one gramme of antitoxin was injected. He complained of intense soreness afterwards. At midnight the nurse had to give him 40 gr. of chloral hydrate, according to orders, as he was so restless. He tossed about, moaning, all night, and complained especially of pain in his right elbow. At 9 A.M. on

the 27th he expressed himself as better. The spasms were not so painful. There was no pain on breathing. One gramme of antitoxin was injected. He had a fair day, and slept on and off from 6 to 9 P.M. At 9.45 P.M. he had intense pain all over the back; the muscles were hard and rigid. One gramme of antitoxin was injected. On the 28th he had little or no sleep during the night. At 1.45 A.M. he had 40 gr. of chloral hydrate without any calming effect. He said that the antitoxin the preceding night had made him feel very ill, drawing up his abdominal muscles and making his "chest and belly fasten together." The nurse said that his breathing was irregular. At 2 P.M. he had slept four hours during the morning; he had very little muscular spasm, although the right arm was still very rigid. He said that he felt better. At 6.30 P.M. he was comfortable and had slept for an hour. On the 29th, at 9 A.M., he was stated to have slept well during the night, with no attacks of spasm. He had a slight tendency to convulsive spasm now in the right arm. The tongue was very dirty and the breath most offensive. The whole skin seemed to exhale a most disagreeable odour; 5 gr. of calomel were ordered, which soon acted. At 9.30 P.M. he had had a good day. There was a clonic spasm of the right arm, lasting about two minutes, caused by touching him. He could swallow fairly well. At 11 P.M. he had one teaspoonful of the compound syrup of bromide of potash, chloral hydrate, cannabis indica, and hyoscyamus. He fell asleep at once and had a fair night. On the 30th, at 9 A.M., a very slight movement of the bedclothes brought on clonic contractions in the right arm. He could swallow liquids pretty well. At 9.30 P.M. he had had a fair day. A friend, on visiting him, gave him some butter-scotch, which he was unable to chew. On the 31st he had had a good night, although awakened by painful spasms three times. They were of shorter duration. "Comes like a gunshot now from fingers to elbow, and off like a shot again." At 9.30 A.M. he had certainly greater tonic contraction in the right arm, and the neck muscles felt board-like. At 9.30 P.M. a fair day had been passed, though the pain had rather increased. He complained of his skin tickling. On Sept. 1st, at 9 A.M., he had had a restless night, being awakened several times by spasms in the right arm. The urine was of sp. gr. 1026, scanty, and loaded with lithates. There was still a disagreeable odour of the skin and breath, and he was covered with an urticarial rash, both body and scalp. He felt his jaws less stiff, but could not put out his tongue, which was still dirty. He had frequent profuse sweats during the day. At 9 P.M. the nurse told me that he had clonic spasms when she went near the bed. When feeling his pulse at the left wrist he had severe spasms of both arms and legs. One gramme of antitoxin was injected. He now confessed that all day he had felt his mouth very stiff, but was afraid to say anything, as he dreaded the injection of the antitoxin. On the 2nd he had several hours' sleep during the night. He got out of bed, but could not stand, and fell down. His tongue was very dirty. Five grains of calomel were ordered, with good result. The rash was fading. At 5 P.M. he had had a better day, but was very feeble. At 9 P.M. he had a painful spasm, which was very severe in the arms and neck. One gramme of antitoxin was injected. The skin over the injection of the day before was very red and tender, almost erysipelatous-looking. The man was very depressed, cried constantly, and had severe sweats. On Sept. 3rd, at 9 A.M., he had had a very bad night, frequent clonic spasms awakening him. He cried out loudly. The nurse gave him 40 gr. of chloral hydrate in the night without any good result. The patient had a very anxious look and heavy sweats. At 10.15 A.M. 40 gr. of chloral hydrate were given, after which he slept until 3 P.M., when the painful contractions of the right arm again awakened him, although they were not so severe. At 5 P.M. he was sleeping quietly. When seen again at 9 P.M. he was sitting up in bed and complained of currents of air in the ward, which caused spasms and queer sensations up his spine. At 9.45 P.M. he had 40 gr. of chloral hydrate and slept until 7 A.M., the contractions, which were much less severe, not awakening him. At 9 A.M. he looked better and more like himself. His old wrinkles reappeared in his face. The right arm was still hard and rigid, yet softer than two days ago. A fresh crop of urticaria was out. Six grains of calomel were ordered, which acted at 6 P.M. During the afternoon he felt the "jaws to be tight, as if the teeth did not fit." He "swallows without the jaws working." At 9.15 P.M. he was lying quiet. He had had fewer chronic spasms of the right arm, but complained of his jaws and left arm. Forty grains of chloral hydrate were given. He slept all night. On the 5th, at 9 A.M., he complained of acute pain in the left hand, which looked as if affected by gout. The hand was ordered to be wrapped in cotton-wool and oiled silk. The fingers were stiffish, but there was no spasmodic contraction. He still swallowed with some difficulty. He felt his jaws stiff "agen t'ears." At 9.30 P.M. he had had a fair day. There had been no spasms of the right arm. Forty grains of chloral hydrate were given. On the 6th he slept well most of the night, without spasms. Mistura alba was administered early, with satisfactory results. The patient looked decidedly better. I opened out his left hand, which still looked gouty. The same kind of dressing and the mistura alba were ordered to be repeated. At 9 P.M. he had had a good day. There had been no clonic spasms. He had had a little milk

Digitized by Google

pudding. On the 7th, at 9 A.M., he had had a good night, although he had taken no chloral, sleeping on and off from 10 P.M. to 8 A.M. He had a cup of tea, with bread in it, for breakfast. The edges of the tongue and gums were sore and tender. The rash had quite gone. The right arm was less firmly contracted, and he could move the fingers a little. At 9 P.M. he had had a good day. On the 8th he slept fairly well without chloral. The right arm and hand were rather more rigid than on the day preceding. He was ordered bread and milk. He said that washing the arm caused slight spasm. He could now put out the tongue a little. On the 9th he had had a good night. The bowels acted, and he had a satisfactory day. On the 10th he had slept well. He could put out the tongue further, although the jaws could not be opened much more than before. He sat up for three hours and had minced beef and vegetable marrow. On the 11th he had had a good night. The tongue was cleaning. He sat up for three hours. On the 12th he had again had a good night. He was out on the verandah in the sunlight for an hour. On the 13th he weighed 10 st. 3 lb., and was sent home, as his wife was anxious for his return. During the next two months he was seen at intervals. The tonic contraction of the right arm, though gradually decreasing, persisted until Oct. 20th. On Nov. 15th he came to report himself. He still complained of general muscular weakness. His weight was 12 st. 3 lb.



Remarks.—In this case the origin of the infection is pretty apparent. The antitoxin was administered in the following way. It was powdered finely in a mortar and dissolved in 90 minims of boiled distilled water. It was then injected, by means of a sterilised syringe, deeply into the muscles of the back. After the first injection great pain followed each succeeding dose, and the tissues round looked red, swollen, and inflamed. The patient had evidently a dread of them, as they made him feel terribly upset for some hours. At first the antitoxin seemed to do good by lessening the frequency and severity of the spasms, but the later injections appeared to cause great and alarming weakness. Although he was carefully fed during the whole time with milk, raw eggs, prepared meat juice, and brandy, he lost nearly 2½ st. in weight. The tonic contraction of the right arm continued nearly six weeks after the acute attack had subsided. The swelling on the ulna also completely disappeared about the same time. It is, of course, doubtful in this case whether either the antitoxin or the chloral hydrate had anything to do with the favourable result, but it is, perhaps, best to publish notes of each patient treated with antitoxin, and it is certainly interesting to compare this case with the one published by Dr. Tirard.[1] Yandell says, in summing up Cowling's report on Tetanus:[2] "Recoveries from traumatic tetanus have been usually in cases in which the disease occurs subsequent to nine days after the injury. When the symptoms last fourteen days recovery is the rule, apparently independent of treatment. The true test of a remedy is its influence on the history of the disease. Does it cure cases in which the disease has set in previous to the ninth day? Does it fail in cases whose duration exceeds fourteen days? No agent tried by these tests has yet established its claim as a true remedy for tetanus." In how many cases has tetanus antitoxin been tried when the symptoms have come on at an early date after the injury, and what have been the results?

Thirsk, Yorks.

A CASE OF CYSTIC TUMOUR OF THE LARYNX.

BY G. HUNTER MACKENZIE, M.D., C.M. EDIN.,
SURGEON TO THE EYE, EAR, AND THROAT INFIRMARY, EDINBURGH.

A MAN aged sixty-seven years applied at the Edinburgh Eye, Ear, and Throat Infirmary on June 4th, 1895, on account of "difficulty in breathing," which had existed in a marked degree for above a year and had become more pronounced during the last three months. For several nights preceding admission he had had scarcely any sleep on account of a sensation of impending suffocation which sometimes caused him to spring suddenly out of bed for relief. He had always enjoyed good health until the onset of his present trouble. His voice was husky, and there was well-marked laryngeal stridor, but no pain. On laryngoscopic examination the cause of his respiratory embarrassment was at once detected. A pear-shaped body with a smooth surface lay upon and obscured the left vocal cord and part of the left ventricular band. It was attached by a short pedicle at or near the anterior commissure of the cords and extended as far as the left arytænoid cartilage. It moved slightly with ordinary

respiration, but during deep inspiration it was drawn below the level of the glottis. The obstructing body was at once removed by the aid of rectangular laryngeal forceps, and a portion of the pedicle which remained was removed by a second similar operation. Immediate and complete relief followed the operation. No recurrence had occurred four months afterwards. After removal of the tumour a somewhat rare condition of the larynx was observed. The left vocal cord, which at first seemed to underlie the tumour, was now found to have completely disappeared, apparently from long-continued pressure and erosion by the growth. A portion of the left ventricular band had been similarly affected.

Remarks.—It is worthy of special notice that two cases of cystic tumour of the larynx in old persons—the one being in almost all respects a duplicate of the other—should have occurred at this *clinique* within a comparatively limited period. The previous case (already reported[1]) was that of a woman eighty years of age who was operated on in a similar manner to the case now under notice, and who is still alive without any recurrence of the tumour. The rarity of these cases is shown by the fact that of 100 cases of growth in the larynx published by the late Sir Morell Mackenzie only two were cystic. The important inference one is justified in drawing from these and other similar cases is that cystic tumours of the larynx after removal show little or no tendency to recur.

Edinburgh.

A CASE OF PELVIC HÆMATOCELE.

BY ERNEST WILLIAM BLISS, M.R.C.S. ENG.,
L.R.C.P. LOND.,
ASSISTANT MEDICAL SUPERINTENDENT, ST. MARYLEBONE INFIRMARY.

THE following case is one of sufficient interest to warrant its being recorded.

A married woman was admitted to the St. Marylebone Infirmary on Aug. 21st, 1895. The history given by herself was that she had always been healthy up to the date of her marriage three years previously. She had one child eleven months after marriage; the labour was normal. Two months after the birth of this child she states that she suffered from "inflammation of the bowels" and was laid up for one month. No history of any other illness was elicited. Her present illness developed one month before admission, when she was attacked by pains about the rectum and all round the lower part of the abdomen. These pains increased in severity for a fortnight, when she passed from the vagina two small clots each about the size of the "end of her forefinger." She had not been unwell for two months before her illness and thought that she was pregnant. On Aug. 9th—that is, twelve days before admission to the infirmary—she became unwell and lost a good deal of blood for about a week, when the flow ceased altogether. On the 17th, four days previously to her admission, she was suddenly attacked by very severe pain in the lower part of her abdomen and felt very faint. She saw her medical attendant, who immediately sent her home to bed, and from that time till her admission to the infirmary she remained in great pain. When first seen there she had an anxious, pinched expression; the temperature was 101·6° F.; the

face was pale and rather sallow, but the body was well nourished. On examining the abdomen there was found occupying the hypogastric region a globular swelling, which was hard to the touch and consistent with the feel of a gravid uterus. The swelling extended about two inches and a half above the symphysis pubis. The breasts were flaccid, and no milk could be squeezed from them. Examination per vaginam disclosed no discolouration of the vaginal mucous membrane. The os was fairly hard and round and was not dilated. Bimanually a large globular mass could be felt occupying the pelvis in the middle line, but extending more to the right than to the left side. The patient's condition remained much the same for the next few days. The temperature ranged from 99° to 103°, generally being raised most at night. She complained of very severe pelvic and abdominal pain, which was much exaggerated when the bowels were moved. During this time the pelvic swelling increased slightly in size, especially laterally. On Sept. 3rd chloroform was administered and a thorough examination made. The uterus was made out to be quite distinct from the swelling, and to be pushed high up behind the pubes; it was reached with difficulty. In Douglas's pouch there was a large swelling bulging the posterior vaginal wall forwards and extending laterally on both sides of the pelvis, but more so on the left side. This was the reverse of her condition on admission. Bimanually fluctuation could be distinctly made out in the swelling. From this time (Sept. 3rd) to Sept. 13th the patient's condition remained about the same. The temperature was raised, and pain continued. The pelvic swelling, if anything, increased laterally, but not much change was observed. On the morning of Sept. 13th she began to pass blood per vaginam, and during that day she passed a number of clots of blood. From the moment she commenced to lose blood she experienced relief from the pain, and during the whole period of her convalescence she had no return of it. The bowels were moved without pain, and the temperature became normal. For the next two days she continued to pass blood (fluid and clotted), and on an examination being made per vaginam it was found that the whole of the mass occupying Douglas's pouch had disappeared. There was no pain on examination. The os could be made out easily and was in its normal position. The uterus was freely movable. Some roughness could be felt high up in the posterior vaginal wall, and on passing a speculum this was seen to correspond with what appeared to be a rough granulating surface round the opening from which the blood had been discharged. The discharge of blood ceased, and from this time till she left on Oct. 5th she made an uninterrupted recovery.

Remarks.—This case I take to be one of pelvic hæmatocele, and, considering the history of cessation of menstruation for two months, the passage of what she describes as two clots about a fortnight before admission, and the sudden attack of severe pain and faintness four days before admission, I think it was most probably caused by the rupture of an extra-uterine gestation. Unfortunately, the clots first passed were not preserved, and I was therefore unable to examine them. The method of cure in this case is, I think, not its least interesting feature. No operative procedure was considered to be advisable or was attempted. I am indebted to Mr. J. R. Lunn, medical superintendent of the infirmary, for permission to publish this case.

Ladbroke-grove-road, W.

A CASE OF DIPHTHERIA TREATED BY ANTI-DIPHTHERITIC SERUM.

BY W. A. HOLMES, M.D. EDIN., D.P.H. CAMB.

THE patient, a girl aged five years and eleven months, of a plethoric temperament and subject to hypertrophied tonsils, was attacked on April 5th by diphtheria. The parents were told by a neighbour that she thought it was a severe case of mumps. The objective signs were considerable enlargement of the parotid glands in front of and behind each ear, as also of the submaxillary and sublingual glands to such an extent as to hide the real line of the neck. Outwardly it had all the appearances of a severe case of mumps, the glandular swellings being very hard. The temperature was normal; the pulse was full, good, and quite regular. On the soft palate, on the right side, there was a small abscess which broke during the afternoon; the tongue was dry, with a white fur on it; the tonsils were hypertrophied and the uvula was much swollen; the tonsils and pharynx were both covered with an ash-grey looking membrane which did not extend into the pharynx, although it was covered with a glairy-looking mucus, as was also the uvula. In the evening there was neither aggravation nor amelioration of the symptoms, thus indicating that ordinary treatment for diphtheria was holding the disease in check. The following morning at 5.20 A.M. the diphtheria had assumed an alarming state of affairs. The patient was pulseless, the face being livid, the lips cyanosed, and the eyes fixed and covered with a glairy mucus. The fingers up to the hands were cyanosed, the tongue was dry and rolled up like a ball in the mouth, the entire soft palate, uvula, pharynx, larynx, and nose as far as the external meatûs were covered by the diphtheritic membrane, and the breathing was stertorous. She was lying powerless, with an occasional movement of the head to ease the stertorous respiration. The arms when lifted fell like pieces of lead. The skin was very hot, but the temperature was not taken. There was no perspiration. With the patient in such an utterly hopeless state I decided to use anti-diphtheritic serum. I injected 20 c.c. of the serum—i.e., 10 c.c. subcutaneously between the spinal column and scapula on each side. Two minutes after the injection the respiration was easier; in five minutes the stertor was less marked, and on the whole she was much relieved from the embarrassed respiration, giving great relief to both parents and nurse. Two and a half hours after the injection the lividity of the face and the cyanosis of the fingers and lips had been replaced by the hue of health. The temperature was normal; the pulse was good, full, and otherwise normal. Her countenance was now expressive of anxiety, the sclerotics and cornea were free from scum, and the eyes were movable. She was able to lift the hands and arms; the tongue could be protruded half an inch beyond the lips, and was not so dry as previously. With such a decided improvement 10 c.c. of anti-diphtheritic serum were again injected subcutaneously, slightly higher on the back than the previous one on the right. Two hours after this second injection of serum a marvellous change took place in the state of the patient. She now sat up of her own accord and began to speak, but with a difficult phonation, yet every word spoken could be heard and understood; her speech was nasal. Two hours and fifteen minutes after the second injection she recognised and admired a hyacinth which had been brought in and placed in a corner of the room; she also recognised everyone and everything about her. The nurse, who had been in the Monsall Fever Hospital and had had considerable experience in nursing diphtheria patients, said she could scarcely realise the change which had been brought about, remarking that she had never seen so bad a case of diphtheria. The urine voided during the day was scanty, but contained neither albumin nor sugar, and was of specific gravity 1018. To remedy the scantily voided urine, steam from hot water in a basin, and afterwards from a bronchitis kettle, was resorted to. Two drachms of perfumed carbolic acid were added to two pints of water, and the steam produced was allowed to diffuse about the patient for two hours, thrice in the twenty-four hours, at a distance of three feet from the patient. The throat was mopped occasionally with weak Condy's fluid, and flower of sulphur was occasionally blown into the throat until the diphtheritic membrane disappeared. This was done for two days subsequently. On the first day after the injection the quantity of urine voided was much more than on the previous day, and less difficulty was experienced, this being probably due to the carbolic acid reducing the irritation of the renal epithelium. The carbolic acid in no way reduced the good effects of the anti-diphtheritic serum circulating in the blood stream. The temperature was normal and the pulse as satisfactory as before. By the evening the diphtheritic membrane had disappeared from the roof of the mouth, the uvula, and the nose, the pharynx and larynx alone being covered with it. There was a copious, irritating, watery discharge from both nostrils, excoriating the skin below the nasal meatûs down to the margin of the upper lip. On the second day after the injection the general state of the patient was good. There was still the irritating watery discharge from the nostrils, but the parotid and sublingual glands on each side were much softer, the pharynx and larynx were free from the diphtheritic membrane, and urine was voided

Digitized by Google

freely. The temperature and pulse were normal. Any food, either solid or liquid, could now be taken by the patient. On the third, fourth, and fifth days after the injection the general state of the patient was satisfactory. The appetite was good; both temperature and pulse were normal; the tonsils were hypertrophied and the site of the abscess in the roof of the mouth was healed. She appeared as though she ailed nothing, and was able to play with her toys. Anyone who saw her would scarcely believe that she had been so near death, she was now looking so well. On the fifth day the parotid and sublingual glands were normal. On the sixth, seventh, and eighth days after the injection the general state was still satisfactory. The appetite was good, but the tonsils were still hypertrophied. A fresh feature appeared during these days; phonation was difficult, sounds produced could scarcely be made out, and the vocal cords on both sides were in a state of paresis. On the ninth day after the injection the vocal cords had recovered from the paresis, and phonation was normal and easily distinguished. Beyond this nothing out of the ordinary was noticed or complained of until the fourteenth day after the injection, when the patient felt sick and vomited, and was relieved by a saline stomachic. On the fifteenth day after the injection food was not taken so well in the morning; during the afternoon she had several cold sweats and asked to be taken to bed. In the evening she felt well and took some pancreatised fresh milk. On the sixteenth day after the injection, at 4 A.M., the patient awoke the nurse, asking for more milk. Ten minutes later she said, "I am dying, you know I am dying, nurse"—on which the nurse called the patient's parents, who asked her whether the child's pulse was good, when the nurse felt it and replied that it was very good. At 4.15 A.M. the patient drew three deep breaths and passed away.

Barrow-in-Furness.

TWO CASES ILLUSTRATING THE THERAPEUTIC VALUE OF OXYGEN.[1]

BY CHARLES J. MACALISTER, M.D. EDIN., M.R.C.P. LOND.,

PHYSICIAN TO THE LIVERPOOL STANLEY HOSPITAL AND TO THE HOME FOR INCURABLES; LECTURER ON PRACTICAL MEDICINE TO THE ROYAL SOUTHERN HOSPITAL.

CASE 1. *Uræmic coma treated with inhalations of oxygen.*—A man aged thirty-nine years was admitted into the Stanley Hospital, Liverpool, on Nov. 15th, 1894, complaining of pains in his limbs, severe headache, and frequent vomiting. He was a very stout, short-necked man, and he attributed his illness to a series of severe wettings with exposure to cold. His habits had been somewhat intemperate. The presence of slight œdema of the eyelids and of the lower extremities suggested the renal origin of his trouble, and this was confirmed by an examination of the urine, which he informed me had been diminishing in amount for some days. Examined in the out-patient room, it contained rather more than one-fourth albumin. There was no blood and the specific gravity was 1015. The position of the heart beat was masked by the adipose thickness of the parietes, but with the stethoscope the sounds were most audible just below the nipple. They were all closed. The pulse (84) was regular and of good volume, but not very tense. During the ensuing twenty-four hours he passed twenty-five ounces of urine. The temperature was normal. On the morning of Nov. 17th (after sleeping well all night) he seemed drowsy and complained of dark spots floating before his eyes. The respirations were noted as being rather hurried (25 per minute) and the pulse was 82. He had severe frontal headache. The urine contained one-fourth albumin and the specific gravity was 1015. The urea, unfortunately, was not estimated. The bowels had been freely moved three times since the previous day. During the forenoon he vomited several times and in the afternoon became delirious, talking nonsense, but there was no excitement. At 5.30 P.M. it was discovered that he was absolutely blind. His temperature was 100·8° F. The pupils were very contracted and exhibited no reaction to light. There were no muscular twitchings. At 6.30 P.M. he was in a semi-[illegible] condition, from which, however, he could be roused; [illegible] breathing was loud and stertorous; the lips, nose, and [illegible] tremities were somewhat cyanosed. His temperature was [illegible] After this he became more and more deeply comatose, and [illegible] the time of my arrival at the hospital (8.30 P.M.), having been summoned by the house surgeon, the patient was in a [illegible] dition of profound coma, lying on his back, the eyes [illegible] open, with pin-point pupils, all the muscles being relaxed and the face, lips, and extremities being cyanosed. The mouth was closed and he was breathing with loud stertor through the nostrils. The heart was beating tumultuously. The pulse was about 118, poor in tension, and irregular in in strength and rhythm. He was absolutely insensible to pain. The œdema noted at the time of his admission was diminished, there being only slight pitting over the tibiæ. If the man had not been under observation a post-[illegible] hæmorrhage might have been suspected or narcotic poisoning. It was evident that he was suffering from some poison—[illegible] generated—which interfered with oxidation, and it was on this account that I at once inserted into one of his nostrils the rubber tube connected with a cylinder of oxygen and allowed him to inhale the gas very freely—pure oxygen through one nostril, and air through the other. The results were very striking, for the face and lips quickly became less cyanosed, and in about ten minutes he began to try to push the tube from his nose. The pulse was reduced from 118 to 84 beats per minute. The respirations became slower and ceased from stertor, and the pupils were less contracted. He resented the touching of his corneæ. A little later he spoke voluntarily on to his side, but I could elicit no replies to questions. The opportunity was taken of his being on his side to apply a cupping glass over the loin, and the pain which this occasioned effectually aroused him. He sat up in bed and became so violent that assistance had to be obtained to restrain him. He, however, took no notice of questions and made no attempt to speak. He presently relapsed into a drowsy condition, and the oxygen was repeated. An enema of sulphate of magnesia being given in the meantime. Ten minutes later he sat up and asked for a drink. He was now quite conscious, but continued totally blind, and complained of severe headache. There was no return of the unconsciousness, although two days later there was a threatening of it which was again averted by oxygen. The urine in the twenty-four hours measured 108 oz., specific gravity [illegible] and contained one-eighth albumin, with hyaline and granular casts. On Nov. 19th he was able to see light. The ophthalmoscope showed small hæmorrhages, especially in the right fundus. The right disc was blurred, and the left disc and [illegible] were normal. I need hardly enter into all the subsequent details of this case, and it will perhaps be sufficient if I state that he was able to read newspaper print on Nov. 21st. On Nov. 23rd all headache had disappeared, and from [illegible] date until Dec. 6th the albumin rapidly subsided in quantity, at length there was no trace of it, and the man left the hospital perfectly well shortly before Christmas. He was treated, so far as medicines are concerned, with intestinal antiseptics, and no food except milk was given so long as any albumin remained in the urine.

CASE 2. *Morphia poisoning.*—At 11.30 on the night of Oct. 23rd I was hastily summoned to see a young woman who had taken in somewhat rapid succession eight pills, each containing half a grain of morphia. The last pill had been swallowed at 10.15 P.M.—i.e., more than an hour before my arrival. Several medical men had (as is usual in such cases) been called upon, and I found Dr. Murray Mann in attendance. The patient had been able to speak and was aroused when he arrived about an hour previously, and he had with great promptitude applied mustard to the [illegible] chest, &c., and he had also administered one-tenth of a grain of atropine hypodermically. Hence the pupils, which were at first contracted to pin points, I found rather [illegible] medium, but absolutely insensitive to light. Dr. Mann had observed some general bronchitis, and the temperature had been 101·4° F. I found the girl propped up in bed, breathing very slowly (about 8 per minute), and it quickly became evident that the respirations were becoming slower and slower, until they ultimately became reduced to 3 or 4 per minute, and would soon have ceased altogether but for the employment of artificial respiration. It is needless to say that she was absolutely unconscious. The conjunctivæ were quite [illegible] painful stimulation that I could [illegible] of sensation. The face, lips, [illegible]

[1] Abstract of a paper read before the Liverpool Medical Institution on Nov. 28th, 1895.

Digitized by Google

the latter were very cold. The pulse was very frequent and feeble, but perceptible at the wrist. An interesting point was the presence of occasional slight convulsive twitchings of the facial muscles and divergent strabismus, possibly the result of some thebaine in the morphia. To wash out the stomach with permanganate of potash or with anything else was out of the question, because I do not believe she could have lived had the artificial respiration been abandoned, and the operation itself would have been risky, and furthermore, the morphia had in all probability been entirely absorbed by the time I saw the case. Dr. Moore, on my taking charge of the respirations, went for a battery, and at the same time a cab was despatched for a cylinder of oxygen, which reached us at about 12.30 A.M. The vulcanite tube was then pushed back to the pharynx, and the gas was allowed to escape very freely while the artificial respirations were continued. The result was that the face almost immediately became less livid, and the pulse slightly better; but what was of more importance the respirations became voluntary, and the continuance of the artificial respiration became unnecessary. She was allowed to breathe the oxygen for about ten minutes, and the tube was then removed, when the lividity gradually recurred; and it was observed that so often as the oxygen was repeated the cyanosis and respiratory condition improved, and when it was omitted a relapse occurred, so that it was determined to administer the gas at very frequent intervals. After much vigorous stimulation of the buttocks, soles of the feet, and cheeks, there appeared at 3 A.M. some conjunctival reflex, which raised our hopes, but half an hour later she again lapsed into a condition of deep coma. The respirations were 7 per minute and the circulation was manifestly failing. Dr. Carter was at this time called in, and at his suggestion some digitalin was injected subcutaneously. Strong coffee was also injected into the rectum. The oxygen was now given continuously. The respirations improved after this, but the extremities, although surrounded with hot bottles, were very cold, and they were enveloped in hot fomentations. At 5 A.M. our efforts were rewarded by a return of the conjunctival reflex, by some attempt being made to move the arms and legs, and by frowning, &c., when the cheeks were slapped. At 6 A.M. she was quite rousable, and half an hour later we were able to leave her under the charge of Dr. O'Flaherty, who at that time arrived upon the scene. Strange to say, no ulceration or bruising of the buttocks, &c., followed the very powerful flagellation which they had received—a result, perhaps, due to their being at once dressed with lint saturated with hazeline. I mention this because another case of opium poisoning which I attended with Dr. Armstrong some years ago, which was treated with about the same amount of vigour, developed very considerable gluteal ulceration after recovery from the narcosis.

Liverpool.

THE INFLUENCE OF INHERITANCE ON THE TENDENCY TO HAVE TWINS.

By DONALD MACPHAIL, M.D. GLASG.

THE cases published by Dr. Cory in THE LANCET of Nov. 2nd and by Mr. Thomas Wakley, jun., in THE LANCET of Nov. 23rd prompt me to send notes of a noteworthy family history which I jotted down several years ago.

I attended a woman in her confinement when twin girls were born. It was her fifth confinement, but she had not had twins before, though she said "twins were very rife in her family." Her insistence upon the "rifeness" of twins aroused my interest in the matter, and she kindly arranged for me an interview with an old aunt, who gave me the notes I send and said she thought she could get notes of other cases in the family and fuller notes of the cases she mentioned to me. My patient died from phthisis not long afterwards, and her husband married again and left the district, so that the history remains as I first noted it down, probably incomplete. I could get no genealogical facts on the husband's side, though he had won honourable mention by the fact that his first wife's only two children were a pair of twins. His third wife had one child to my knowledge, but of her subsequent history I know nothing. The facts of the case are that my patient's husband's first wife had twins, her maternal grandmother had twins twice, her grandmother's brother's wife had twins, her grandmother's mother had twins, her grandmother's uncle's wife had twins, her grandmother's father was a twin, and his sister had twins twice and triplets once. Arranged according to generations the history seems to be as follows:—

First generation.—		A woman had twins, &c.
Second	,,	One of her daughters had twins twice and triplets once, and one of her twin sons married a woman whose brother's wife had twins, and who herself presented *him* with a pair.
Third	,,	One of *his* daughters had twins twice, and his son's wife had twins once.
Fourth	,,	Blank.
Fifth	,,	A granddaughter of the woman noted in the third generation married a widower whose first wife had had twins and she herself bore him twins.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON A DIET CURE.

By W. A. HATTON, M.D. DURH.

HAVING lately had occasion to make use of one of the so-called "diet cures" for the relief of those symptoms due to an excessive development of fat in some half-dozen cases, I venture to think, as the results were so satisfactory, that a few notes may be of general interest. The plan of treatment followed is that advocated by the late Mr. Towers-Smith, which has the merit of having been tested in his own case. There being an absence of the complicated rules of the various Continental authorities—the treatment being easily followed out with very little hardship by anyone—I chose it for trial. The first case was that of a woman aged fifty years, who weighed 238 lb. on April 5th, and suffered a great deal from dyspnœa and palpitation and was unable to walk any distance. There was no organic disease—which it is always advisable in these cases to look for, and which, if present, precludes most forms of diet treatment. Her measurements were: Round the neck, 14 in.; chest, 40 in.; waist, 38 in.; and abdomen, 51 in. The diet chart would be in accordance with each individual case, but the following may be taken as an average one. At 8 A.M. a tumblerful of hot water flavoured with lemon-juice, tea or coffee plain, no milk or sugar, a little white fish, such as cod or sole; steak or chop, or cold meat, free from fat; at 12 noon, beef or mutton, hot or cold, with or without a pint or so of beef-tea or water; at 4 P.M. a cup of tea or coffee; at 9 P.M. fish or cold meat, one pint of beef-tea or hot water. All food should be plainly cooked; no fat, skin, or gravy to be taken, and no vegetables to be allowed. Drink to be taken preferably after meals. If desired, in suitable cases, a little Scotch whisky, claret, or Burgundy may be allowed, and some exercise should be indulged in daily. There is no starving in this plan of treatment, as from 1 to 3 lb. of meat may be taken daily. The only hardship to many is the absence of bread and butter and vegetables, but that always passes off after the first few days. In lieu of bread Mr. Towers-Smith has devised a biscuit, made of bran and soya, one to be taken at each meal. The above should be adhered to for fourteen days, and as improvement results a little indulgence should be allowed fortnightly. Owing to a misunderstanding this patient ate nothing for fourteen days but beef or cod-fish, and drank tea or hot water, with the result that she lost 14 lb. and felt much improved in her condition; the waist lost ½ in. and the abdominal measurement 1 in. During the next fortnight, in which she followed the above diet chart, she lost 7 lb., the abdomen 2 in. and the chest 1 in. In the succeeding fortnight she lost 3 lb. (the waist ½ in.). A little vegetable food was then allowed every other day. The patient took exercise daily, and could even then walk comfortably a couple of miles. During the next fortnight she

Digitized by Google

lost 4 lb. (the abdomen 3 in.). She was kept to the same diet for a month, when her improvement allowed a little more latitude in her diet, and in two months she could take almost anything. The general result was that she lost 31 lb. in weight, 1 in. in measurement round the chest, 1 in. round the waist, and 6 in. round the abdomen. Nearly all her discomforts have disappeared, and she can now walk from six to eight miles with little fatigue. The other cases gave as satisfactory results. The method of treatment will compare favourably, I think, with those of Ebstein, Oertel, or any other of the many Continental methods.

Westhoughton, Bolton.

ON THE EXTRAVASATION OF BLOOD IN TUBAL PREGNANCY.

BY JAMES OLIVER, M.D., F.R.S. EDIN.,
PHYSICIAN TO THE HOSPITAL FOR WOMEN, SOHO-SQUARE, LONDON.

DURING the evolution of a natural pregnancy there results not only an augmentation in the size of the bloodvessels of the uterus, but a hypertrophy of the tissues of this organ generally. When, however, the fecundated ovum develops in the Fallopian tube it seldom happens that any vigorous local growth is excited by its presence, although the bloodvessels in the involved tube become greatly enlarged. Apart from any intrinsic disease the integrity of a bloodvessel depends greatly upon the manner in which it is supported by the surrounding tissues. When, therefore, the pressure exerted by the Fallopian tube against a growing ovum is insufficient to support the correlatively enlarged bloodvessels they rapidly become thinned, and rupture with extravasation of blood takes place on the slightest provocation. When the developing ovum is located in the cavity of the uterus we are accustomed to believe that accidental hæmorrhage from the maternal vessels never takes place until after the fourth week of pregnancy. Whether this belief be correct or not it is evident that in tubal pregnancy accidental hæmorrhage from the vessels in the mucous lining of the Fallopian tube may occur as early as the seventh or tenth day after impregnation. In ectopic pregnancy, therefore, blood may be extravasated from the maternal vessels before the chorionic villi become vascular—a phenomenon which happens during the third week of pregnancy when the chorion becomes incorporated with the allantois. The paroxysmal attacks of severe pain which are sometimes experienced in cases of tubal pregnancy are due to these effusions of blood, and, although the primary hæmorrhage occurs always whilst the ovum is living, subsequent hæmorrhages may nevertheless happen after this body has died. Rupture of the Fallopian tube itself, which has gradually become more and more thinned, may be induced by the first or any succeeding extravasation of blood; and as this accident may occur as early as the fourth week of pregnancy before the chorionic villi have begun to participate in the formation of a true placenta—for the ovum is everywhere placental at this period—the breach in the continuity of the tube is not in all cases at least attributable to a thinning at the placental site, or to a penetration of the tube by the villous processes. A portion of the external hæmorrhagic discharge — vaginal — which is observed in the early days of some tubal pregnancies comes directly from the ruptured vessels in the tube.

Gordon-square, W.C.

BILATERAL VARIATION OF TEMPERATURE.

BY BINGLEY G. PULLIN, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.

A CASE of typhoid fever, contracted in the South of Europe, was lately under my care during its course, which ended fatally from peritoneal abscess. The subject of temperature revealed itself in an altogether new light. Accidentally, I found that the temperatures on the opposite sides of the mouth varied at the same time and with the same clinical thermometer. I became interested to ascertain whether or not this difference existed from day to day, and requested the trained nurse to take the temperature on both sides of the mouth (between the cheek and teeth) every four hours. Strange to say, on nearly every occasion the highest reading was on the left side (the abscess ultimately showed itself on the left side). During the time these records were taken exactly 100 temperatures were notified; on twelve occasions only did the temperature of the right side exceed that of the left, and only three times were the temperatures equal. It would be impossible to notify in an article each record, so I merely take the averages of the day's temperature for the last fifteen days of the illness.

First	day	0·9°	higher	on	the	left side.
Second	,, ...	0·6	,,	,,	,,	,,
Third	,, ...	1·0	,,	,,	,,	,,
Fourth	,, ...	0·9	,,	,,	,,	,,
Fifth	,, ...	0·5	,,	,,	,,	,,
Sixth	,, ...	0·9	,,	,,	,,	,,
Seventh	,, ...	0·9	,,	,,	,,	,,
Eighth	,, ...	0·7	,,	,,	,,	,,
Ninth	,, ...	0·6	,,	,,	,,	,,
Tenth	,, ...	0·4	,,	,,	,,	right ,,
Eleventh	,, ...	0·5	,,	,,	,,	left ,,
Twelfth	,, ...	1·2	,,	,,	,,	,,
Thirteenth	,, ...	1·2	,,	,,	,,	,,
Fourteenth	,, ...	1·0	,,	,,	,,	,,
Fifteenth	,, ...	0·5	,,	,,	,,	,,

The greatest difference recorded was 3·2° in favour of the left side; many times a difference of 2·0° was noted. Now, looking at this case, supposing that each time the temperature was taken it had been taken on the right side, what would have been seen? Nothing certainly alarming in the temperature of the case, as the highest record on that side was 102°—very rarely did it exceed 100°; whereas on the left side it rarely fell below 102°, and did on one occasion reach 104·8°. If we are to be guided by temperature charts, is it not of the highest importance that both sides of the body should be tested? It would certainly, to my mind, aid one very much in deciding on which side in most cases we have to meet disease, for it is evident that under the influence of some irritating cause the vascular system of the opposite side of the body is contracted, consequently there is less blood and the temperature is lower; *vice versâ* on the offending side. Many cases of a minor degree have since this been noticed by me.

Sidmouth, Devon.

NOTES OF A CASE OF THREATENED FATAL RESULT FROM CHLOROFORM ANÆSTHESIA.

BY J. C. MAXWELL, M.A., M.B., C.M.,
SENIOR HOUSE SURGEON, HALIFAX INFIRMARY.

THE patient, a strong healthy man aged thirty-nine years, was being anæsthetised on Jan. 3rd previously to operation for a small omental hernia in the neighbourhood of the umbilicus; chloroform was the anæsthetic selected, and was administered on a folded towel, the patient's head being kept low and the jaw pulled well forwards. The patient took the anæsthetic well, did not struggle, breathed regularly and quietly, and had been receiving the anæsthetic for about seven minutes without being fully anæsthetised; the abdominal muscles contracted when touched, and there was a well-marked conjunctival reflex in both eyes. The pupils were about 2·5 to 3 millimetres in diameter and reacted to light. The right carotid pulse was of good volume. Administration was continued, but no fresh chloroform was poured on the towel. In less than thirty seconds after the above observations the pupils suddenly dilated and became immobile, and the conjunctival reflex disappeared. The towel was removed, but after two or three breaths respiration entirely stopped and the carotid pulse became much feebler. The head was pulled over the end of the table, the tongue pulled out, and artificial respiration (Sylvester's method) at once resorted to. During its performance two hypodermic injections, each $\frac{1}{100}$ grain of sulphate of strychnia, were given and a current of oxygen gas was played about the nostrils. At the end of twenty minutes the patient vomited and showed signs of recovery, his pulse became stronger, and respiration took place normally. He was still much collapsed and the operation was abandoned. About two and a half drachms of chloroform had been used.

The case seemed to be one of paralysis of the respiratory centre in the medulla, coming on practically coincidently with the abolition of the abdominal and corneal reflexes. A week later the patient was again anæsthetised, this time with ether from a Clover's inhaler. The patient took the anæsthetic quietly and did not struggle or hold his breath till five minutes after the commencement of the administration. He

Digitized by Google

then passed into a condition of complete muscular rigidity, the chest-walls being rigid, the teeth clenched, and the arms and legs stiff. The pupils were dilated. The pulse-beat was much feebler. The mask was removed and in a little the spasm relaxed and the patient began to breathe. On re-application of the mask he passed off, without causing further trouble, into normal anæsthesia maintained for thirty-five minutes. It may be of interest to mention that he had retention of urine for three days after the operation.

WEST LONDON HOSPITAL.

A CASE OF TRAUMATIC TETANUS TREATED BY ANTITOXIC SERUM; RECOVERY.

(Under the care of Dr. ALDREN TURNER and Mr. G. LENTHAL CHEATLE.)

THE cases of acute traumatic tetanus treated by the antitoxic serum are sufficiently rare to warrant the publication of this one, which was under observation for a considerable time in the wards of the West London Hospital. It is an illustration of the effect of a comparatively new remedy, which, according to Dr. Turner, was of undoubted value in lessening the frequency of the general spasms. Cases of tetanus have recovered under nearly every form of treatment, and there are many remedies, but no specific cure. Chloral hydrate has probably given the best results, but is uncertain. It is important that the antitoxin should have a fair trial, but few surgeons would be inclined to practise preventive inoculation with it. Tetanus is now a very rare disease, even in our large hospitals, and the cases are usually admitted from without, whilst the thorough antiseptic cleansing of contused and lacerated wounds when they present themselves for treatment is most effectual in preventing its development. For the notes of the case we are indebted to Mr. E. Bromet, house surgeon.

The patient, a boy aged six years, was brought to the hospital on Aug. 1st, 1895, his mother making the statement that he was suffering from stiffness of the legs and neck. On further inquiry it was found that about a fortnight previously he had fallen on a piece of barbed wire and sustained a wound on the ball of the left thumb. Rather more than one week after this injury the patient is stated to have had a fit, in which, according to his mother's account, he became stiff all over and bit his tongue; and after the fit he was unable to open his mouth properly. At the time that the stiffness commenced the wound, which had not been treated surgically, showed an unhealthy appearance. The patient had never previously to this attack had anything of the nature of a fit. The mother was not absolutely sure of the dates, but as far as cross-examination could elicit the length of time between the injury and the onset of tetanic symptoms was eight days. On admission there was found a small suppurating wound on the ball of the left thumb. The limbs were stiff and painful when moved. There was also slight opisthotonos. The mouth could not be opened further than to admit the tip of the index-finger. The fingers were rigid and contracted. The child was quite sensible and complained of the stiff feeling of the limbs and soreness about the lower jaw. The slightest movement or attempt to administer food set up a typical tetanic convulsion. The jaws were tightly closed, the face muscles were rigid, with a well-marked risus sardonicus, extreme opisthotonos, clenching of the hands, rigidity of the muscles of the abdomen, expansion of the chest, and a peculiar sobbing noise during inspiration. About 6 P.M. on the day of admission the house surgeon, acting on the advice of Dr. Turner, freely excised the wound under chloroform. The piece of tissue, which consisted of one or two small granulations, some cicatricial tissue, and healthy skin, was submitted to a careful bacteriological examination by Dr. W. Bulloch of the British Institute of Preventive Medicine, but no tetanus bacilli were detected after staining by the usual methods. On recovery from the effects of the anæsthetic, the spasms again set in with renewed vigour and frequency, so as to necessitate the constant administration of chloroform. The slightest reduction of the anæsthesia was immediately followed by recurrence of the tetanic spasms already described. The chloroform anæsthesia was maintained from 8 P.M. on the day of admission (Aug. 1st) until midday on Aug. 2nd. During the afternoon of this day the spasms, which still remained very frequent, appeared to be less severe. At 5.30 P.M. a supply of antitoxic serum arrived from the British Institute of Preventive Medicine. One gramme of this was injected, under strict antiseptic precautions, subcutaneously into the abdominal wall.[1] For the purposes of injection the serum, which had been sent in the dry crystallised form, was dissolved in distilled water previously boiled. During the six hours which elapsed between the first and second injections only one convulsion occurred, and during this period the boy sat up in bed and asked for milk. Previously he had been fed by enemata, and the urine was drawn off by the catheter. At 11.30 P.M. on Aug. 2nd the second injection of one gramme was given. During Aug. 3rd there was only one slight spasm recorded. A good deal of muscular rigidity still remained, more especially of the abdomen. During this day the general condition had improved, he took milk freely by the mouth, and passed urine and fæces naturally. At night 0·5 gramme was injected. From Aug. 4th to 7th no further spasms occurred, although rigidity remained. Under the belief that this abdominal rigidity was of a tetanic nature another gramme was injected on Aug. 7th. The total amount injected was therefore 3·5 grammes (equivalent to 35 c.c. fluid form). On Aug. 11th several localised abscesses were detected in the abdominal wall at the seat of the injections. An erythematous rash in blotches was observed for the first time on the abdomen and face. On Aug. 13th the rash was more profuse and the abdomen tender and rigid. The abscesses were opened and dressed in the usual way. On Aug. 18th the abdominal rigidity had almost entirely disappeared. The general health was excellent. The patient was allowed out of bed. On Aug. 24th an abscess which had formed in the left lumbar region at the seat of the last injection was opened. On Sept. 4th the patient left the hospital in good health. On Nov. 13th the mother stated that slight "jerking attacks" had been at times observed after leaving the hospital, but they were infrequent and mild. The boy was in the best of health. No attacks had been observed for the past ten days.

Remarks by Dr. ALDREN TURNER.—The points to which attention is especially called are, firstly, the nature of the case, and, secondly, the method of treatment. It is difficult to say in how far recovery was entirely due to the treatment by the antitoxic serum; but the case is of value for statistical purposes, and for the same reason it is hoped that the unsuccessful as well as the successful cases may be recorded. From the point of view of incubation the case may be regarded as acute, this period being of eight days' duration. But the more or less gradual onset of the symptoms places it amongst the milder forms, which, according to the statistical tables drawn up by Kanthack,[2] as a rule present a favourable prognosis. Setting aside the question whether the case would have recovered without the aid of the antitoxic serum, I submit that no drug, or other method of treatment at present at our disposal, could have brought about the extraordinary arrest of the tetanic symptoms mentioned in the report. For the twenty hours preceding the first injection the spasms were so severe and so frequent that it was necessary to maintain a chloroform anæsthesia. During the six hours succeeding the first injection one spasm occurred, and during the twenty-four hours following the second only one slight spasm was recorded, since which there has been no recurrence with the exception of the slight "jerking attacks," to which further reference is made later. Not only was the arrest of the spasms remarkable, but the improved state of the general health was most noteworthy. As regards the method of treatment, I desire to point out that the serum was obtained in its dried form, being sent direct to the

[1] According to Dr. Hewlett one gramme of the dried serum is equivalent to ten c.c. of the fluid form.
[2] Medical Chronicle, 1895, p. 92 et seq.

Digitized by Google

hospital from the British Institute of Preventive Medicine. The crystals were dissolved in distilled water previously boiled, the hypodermic syringe and needles had also been boiled, and the skin was carefully washed with carbolic acid solution (1 in 20). Yet, notwithstanding these precautions, an abscess formed at the seat of each injection. It appears clear that the serum crystals must have conveyed the septic agent; and this I take to be the chief objection to the dried method of preparation. As is not uncommon, the injections gave rise to an erythematous rash, which was not troublesome and did not last long. But a point of some importance, and one to which I wish to direct attention, is the continuance of so-called "jerking fits," with a certain amount of rigidity associated with them, for some time after all other tetanic symptoms have disappeared. It may be suggested, and with some reason, that as long as these attacks persist the case ought not to be regarded as a cure. It is yet a matter for conjecture what the cause of those late jerking fits may be. Should they be regarded as resulting from the treatment adopted, or are they to be looked upon as evidence of retention in the system of some of the products of the tetanic poisoning? It is to be noted that in this case the serum treatment was not applied until the eighth day after the onset of the tetanic symptoms, by which time certain products of a strychnine-like nature have been formed between the tetanus ferment and some of the organic products of the body, which the antitoxic serum was unable to neutralise; and this is the view suggested by Courmont as a likely explanation of the late phenomena. In relation to this matter Dr. Bulloch tells me that he has noted similar late "jerking attacks" in a horse in which he had artificially produced tetanus and then cured by the injection of antitoxic serum. In this instance only two days elapsed between the onset of the symptoms and the commencement of treatment. The point, therefore, appears to be of considerable scientific importance, and it is desirable that the presence or absence of these late jerking attacks should be noted, as well as the date of the first injection after the onset of the tetanic symptoms. Whatever the products may be, they are gradually eliminated by the usual channels. Lastly, it should be pointed out that although we have in this method of treatment a most potent therapeutic agent for the prevention as well as the cure of tetanus, early excision of the wound should never be neglected. Although in this case, as in many other cases, examination of the wound by an experienced bacteriologist failed to show the presence of Nicolaier's bacillus, yet there is reason to believe that it is a fountain for the constant supply of the toxic ferment.

TAUNTON AND SOMERSET HOSPITAL.

A CASE OF TETANUS TREATED WITH TETANUS ANTITOXIN; DEATH ON THE FIFTEENTH DAY AFTER ONSET OF SYMPTOMS.

(Under the care of Mr. SAMUEL FARRANT.)

ALTHOUGH the treatment of tetanus by antitoxic inoculation is older than the analogous treatment of diphtheria, yet the disease is so much rarer and the cases of recovery under the treatment so much more *sub judice* that all records of cases so treated, however negatively, become most important. Therefore we are glad to present our readers with a third account of a case this week. The injury in the case related in our columns this week by Dr. Hartley of Thirsk should have had its origin, as has the case which follows, in a kick from a horse; for of course it is only a coincidence and not a point of any pathological meaning. For the notes of this case we are indebted to Dr. Maidlow, house surgeon.

A man forty-six years of age was admitted to the Taunton and Somerset Hospital on Oct. 29th in an alcoholic state, with a history that he had been kicked on the face by a horse two hours previously. The patient had the appearance of a chronic alcoholic. After removing as much mud as possible it was found that there was a lacerated wound one inch long running downwards and to the right from the right nostril; another, starting from the anterior part of the septum nasi, passed through the lower right lateral nasal cartilage upwards and outwards, so as to almost separate it. The nasal mucous membrane of each side was also lacerated. The wounds were thoroughly cleansed, and were finally syringed with a carbolic acid solution (1 in 20); the nose after having been sewn up was dressed with blue gauze soaked in styptic colloid, the other wound having a similar dressing. Except for some difficulty in keeping the interior of the nose clean both wounds healed well, and in fact presented at no time indications for special treatment. The patient's previous health had been good, although he admitted alcoholism. Ten days previously he had had a molar tooth removed. On the 30th he felt quite well, the temperature being 97·3° F. No albumin was found in the urine. He got up and walked about. There was no evidence of visceral disease. On Nov. 3rd he said "his jaws felt stiff," but nothing was noticed. He took food well. The face was rather swollen and hot, and the patient appeared to be on the eve of an attack of facial erysipelas. The temperature was normal. On the 5th there was marked trismus. Both masseters were firmly but not painfully contracted; they remained in this state persistently without exacerbations. No other spasms occurred. There seemed to be tenderness over the right lower molar, and as he could give no account of the tooth previously removed it was thought this might be the source of a reflex trismus. The treatment consisted in applying boracic fomentations. On the evening of the 6th he had a severe respiratory spasm for nearly four minutes; the nurse thought that he was dead. The patient's body was thrown in all directions, and his distress seemed to be great. On the 8th an attempt to open the mouth with a gag failed, but two lower teeth were removed, having been loosened in this attempt. Soon afterwards another respiratory spasm occurred, which seemed to be due to a difficulty in removing collected blood. There was no dysphagia, the patient taking milk, beef-tea, &c., by the mouth. On the 9th there was no change in the condition of the jaws; otherwise he seemed to be comfortable. He was given a purgative and chloral hydrate (twenty grains every four hours). On the 10th painful swallowing supervened. On the next day (the 11th) a severe spasm occurred during an attempt to pass a nasal tube. After chloroform had been administered an examination of the teeth revealed that they were all apparently sound; in fact, there was now no doubt about the diagnosis. The only rigid muscles were the masseters. From the 11th to the 12th no fresh symptoms developed. The patient was fed every four hours with nutritive enemata containing fifteen grains of chloral hydrate, twenty grains of bromide, and ten minims of tincture of opium. The temperature was normal and he seemed cheerful. On the 13th it was noted that during the night his arms had twitched during sleep and that severe attacks of dyspnœa occurred at 11.15 P.M., 1.15 A.M., and again at 8 A.M. and 11.45 A.M.; there was no exciting cause. He complained chiefly of backache. The sterno-mastoids and masseters were extremely but not painfully rigid. No risus sardonicus was present. The pulse was 139 and regular, the respiration 38, and the temperature 100°. There was a trace of albumen in the urine. Chloroform was given on an inhaler during each attack, and seemed to cut them short. At 1.15 A.M. tetanus antitoxin obtained from Messrs. Allen and Hanbury's, fifteen grains (British Institute of Preventive Medicine), was injected into the lumbar cellular tissue. At 2.35 P.M. a sudden severe spasm occurred during sleep. No special opisthotonos was observed; the body was thrown about in all directions during this attack. There was complete retention universally afterwards. Another slight attack occurred at 4.30 P.M. From this time he never had an attack so severe as to necessitate the use of chloroform. At 11.10 P.M. fifteen grains of antitoxin were injected. On the 14th, at 5.30 in the morning, there were two mild attacks. During the day the muscles of the abdomen were rigid, and the sterno-mastoids and masseters occasionally so. The temperature during the day ranged from 97° to 101°. Another injection of fifteen grains was made at 4 P.M. The patient was still fed per rectum, but the chloral and opium were discontinued. In the evening muscular twitchings and delirium developed, the mouth being always full of a viscid blood-stained secretion very difficult to remove. On the 15th he was very depressed, but he had experienced no marked attacks since the morning of the 14th. The pulse was feeble and irregular. An injection of nineteen grains of antitoxin was given. In the evening he was delirious. Three minims of morphia were injected hypodermically. His muscles were now rigid. On the 16th he was [illegible] and delirious. A severe, but compared with the [illegible] spasms a mild, attack occurred at [illegible] tinued to improve all day and [illegible]

but seemed to be afraid. Ten grains of antitoxin were injected. He was in a moribund state during the night, but occasionally fought vigorously and seemed to be conscious. At 8.30 A.M. on the 17th he died suddenly during the passage of food through the nasal tube.

Necropsy (partial).—No evidence of disease was found in any viscus excepting some fatty changes in the liver and pulmonary emphysema. The brain and spinal cord were not examined. Thirty hours afterwards the arms were discovered to be lax, the jaws and lower extremities being still very rigid. Decomposition was not marked.

Remarks.—The most salient points of this short history seem to be as follows. 1. The onset of the attack (the fourth day from probable inoculation) was acute; yet from the onset to the first definite dyspnœic spasm (the seventh day) till the first antitoxin injection, when he seemed to be well "in" the disease (the fifteenth day), the course of things was slow, in opposition to the usual rule that the course of the disease varies directly in acuteness according to the rapidity of the onset. 2. The only obvious rigidity, except for the various contortions of the patient's respiratory spasms, was in connexion with the masseters, sterno-mastoids, and abdominal muscles, whilst towards the end he could open his mouth and drink. 3. The spasms quite as often as not occurred while he was asleep, but the region of the fifth nerve seems to have been especially irritable. A severe attack occurred during the first passage of the nasal tube, when he seemed in need of stimulant at all hazards and the spasms seemed to have stopped. His death seemed to be due to the shock of passing the tube and feeding thereby (post mortem all the milk was found in the gullet and stomach, although air passed out of the tube as it was being passed). 4. The relief by inhalation of chloroform appeared to be great, but it seemed inadvisable to give chloroform in order to feed by nasal tube whilst enemata were retained. 5. Although the man seemed to be a typical and confirmed drunkard, yet he took chloroform (deeply) quite well, and no great visceral changes were found. Still, with a more favourable subject the necessarily depressing treatment would have been better stood. As to the chloroform, the exhaustion by long-continued spasms would have been greater, I think, than the temporary depression caused by the anæsthetic. 6. As regards diagnosis, the history, the tenderness over the right lower wisdom tooth, the possibility of such a cause, and the persistent tonicity of the masseters gave a hope of reflex spasm at the onset, whilst the history of the wound and its position made the possibility of tetanus great (I may say experimental inoculations were not made, but no specific bacilli were to be found in the wound when examined on the fourth day after the onset). 7. The great difficulty in getting at the nose and the septic condition there make it only too probable that he absorbed fresh doses of poison from this quarter, a fact which reminds one of the malignancy of "nasal" diphtheria. 8. As regards the important question of the antitoxin injections, I will refer to the following points. (1) Concerning the preparation directions are given to dissolve about fifteen grains in one drachm of sterilised distilled water. This hardly dissolves it without immersion in warm water outside; a sticky mass is liable to form. Directions are also given to weigh and pound; absolute sterility is hard to obtain in these manœuvres. (2) As to the cost, we wrote expecting to pay 45*s.* per four and a half grammes (about seventy grains), but found the British Institute of Preventive Medicine makes it at 6*s.*, which is a great advantage. (3) In connexion with the result, although spasms did not cease they become markedly less numerous and less severe, but at the same time the patient grew weaker. The temperature taken half an hour before and after the injections showed no change to speak of, but the pulse became stronger for an hour or two afterwards. Was the patient's release from severe spasms due to the prostration from the disease, from the antitoxin, or from insufficient feeding? If spasms are the signs of the disease, and I do not know of a case described without spasms (compare rheumatism without arthritis), it seems unlikely that the disease itself, as it were, "spent its fury"; in ten days a fat man with well-prepared nutrient enemata would not become so exhausted from want of food. Consequently the antitoxin must be turned to. He had five injections of fifteen grains (nearly). If immunity from spasms was due to the antitoxin, and leading writers on the subject have recorded no bad effects from tetanus antitoxin on even a healthy subject, as I believe to be the case, would it have been justifiable to suspend the treatment? The severer spasm on the day before death seems to indicate that the poison was still circulating, that the antitoxin had been efficacious, and that the weakness and prostration were signs of toxæmia, but not of toxæmia due to the tetanus antitoxin. Whence I conclude that had the patient been a more favourable subject, had the nose been better able to be disinfected, he might have lived; that he was better for the treatment he had; and that it is advisable to know more of the effects of the tetanus antitoxin itself, so that we may exclude from a patient's condition any dangerous effects of the treatment; then also we may be justified in prophylactic inoculations in all suspicious wounds.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Discussion on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues, as in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, &c.[1]

THE following is the continuation of the discussion on the above subject at the ordinary meeting of the society held on Nov. 26th, the President, Mr. HUTCHINSON, being in the chair.

Dr. KINGSTON FOWLER said that he had been asked to state as concisely as possible the pathological and clinical evidence for the belief that it was possible for the specific poison of tuberculosis to remain latent in animal tissues. The general argument put forward was as follows: (1) that the disease, having been arrested, might after a period of quiescence again become active, and that reinfection took place from within; (2) that tuberculosis might be produced by the inoculation of an animal with material taken post mortem from an old tuberculous lesion; and (3) that the virus of the disease might pass directly from the parent to the offspring, and that it might reproduce the disease in the tissues of the child. The facts stated were chiefly drawn from cases of pulmonary tuberculosis. Reference was made to the frequent discovery of obsolete tuberculous lesions at the apices of the lungs and to his published work on Arrested Pulmonary Tuberculosis. If recrudescence of the disease coincided with changes in the old lesions, and recent miliary granulations were first formed around them and spread thence through the lungs, the inference was that reinfection had started from within. This would be confirmed if it should appear that the individual was in apparently perfect health until the occurrence of some symptom pointing to the presence of an old lesion—e.g., hæmoptysis. A case fulfilling these conditions was described. A man aged fifty-three had, when a boy aged thirteen, an illness said to have been "consumption"; with the exception of an attack of pleurisy, he had subsequently enjoyed good health. He was of good muscular development, of healthy appearance, and generally regarded as a strong man. In February, 1888, whilst in his usual health, he had an attack of hæmoptysis. A few days later some fine crackling râles were audible at the left apex. Death occurred in twenty-eight days from acute tuberculosis of the lungs. On post-mortem examination a sharply defined yellow caseous mass the size of a large olive was found at the left apex. Its capsule, elsewhere firm and fibrous, had broken down at one spot and had established a communication with a bronchus. Half the mass had disappeared, leaving a small rugged cavity. Recent miliary tubercle was present throughout the left upper and lower lobe and also in the right lower lobe. A precisely similar caseous mass, intact and firmly encapsuled, was found at the right apex. The inference from the facts was that the virus of the disease had lain dormant in the caseous mass for forty years. A case of acute tuberculous pericarditis was described in which the pericardium alone showed recent tubercle, but at the apices of the lungs old obsolete tubercle was found post mortem, as also a calcareous bronchial gland. Tubercle bacilli were found in the pericardial lesion. The period of latency was believed to have been four years. Attention

[1] Continued from p. 1362.

Digitized by Google

was called to the extreme rarity of acute tuberculous pericarditis apart from general acute tuberculosis, and to the great improbability of primary infection of the pericardium from without. A case was cited to prove that obsolete lesions are capable of causing reinfection. Dr. Sidney Martin's researches on Tuberculosis were referred to, and a case was described in which inoculation of a guinea-pig with caseo-calcareous material, probably about 200 days old, had resulted in acute tuberculosis. Also some experiments by the same observer were mentioned in which inoculation with matter from old pulmonary lesions found in the bodies of two patients dying from cancer had not been followed by tuberculosis. Attention was directed to the importance of the dose in experimental inoculation and in infection of the human subject. The researches of Landouzy and Martin were referred to as proving that general tuberculosis might be produced by the inoculation of material from a fœtus, the mother being tuberculous, when no obvious signs of tubercle were present in the body of the child. Straus had repeated these experiments, but without success. The theory of Baumgarten was described. Baumgarten believed that direct transmission of the virus from parent to offspring was followed by latency of the virus in the child, and that this was the common mode of infection; that the influence of inhalation had been much exaggerated; that lesions in the fœtus were absent because the number of bacilli was small; that the virus might remain dormant for long periods in the lymphatic glands and in the medulla of bones; and that the tissues of the fœtus possessed a special resisting power owing to the activity of cell growth. The evidence in favour of the possibility of the transmission from mother to offspring through the placenta was stated, and four cases, described by Birch, Hirschfeld, Schmorl, and Kockel, were narrated. In all the cases tubercle bacilli were found in the fœtal placental villi, and in one in the liver of the fœtus and in a lymphatic gland near to it. Three cases of mixed infection of tubercle and syphilis in infants reported by Hochsinger[2] were referred to, and the evidence was given at length. The parents were both syphilitic and tuberculous. In all the cases there were well-marked signs of constitutional syphilis, including an eruption on the nates and snuffles. In all of them the diagnosis was visceral syphilis, and the patients were shown as suffering from it before the Vienna Dermatological Society. In all the internal lesions were found post mortem to be tuberculous and not syphilitic, and to contain tubercle bacilli. The reasons were stated for the view that infection in these cases was from the placenta and not from without. The opinion was expressed that the evidence in favour of the possibility of a tuberculous mother infecting her child was convincing, but no support was given to Baumgarten's view that this was a common mode of infection, and certainly not the most common. The evidence in favour of the possibility of a prolonged period of latency in the child after infection from the mother was considered to be at present defective, but the opinion was expressed that in the future direct infection from the mother would be shown to be of more frequent occurrence than was at present believed. Reference was made to the further development of Baumgarten's theory—viz., that the virus might lie latent for several successive generations, and that a child might have been infected by a tuberculous grandmother, the mother having been free from the disease. Mention was made of the Pébrine disease in silkworms, and the inoculation experiments of Maffucci on impregnated hen's eggs, which were considered to give support to this view. The opinion was expressed that it need not be seriously considered until it had first been proved that the direct transmission of the disease from mother to offspring was an event of common occurrence, and that in such a case it was possible for the virus to lie latent for a long period in the body of the child. The shortest period of latency of the virus could hardly be determined by clinical and pathological evidence. In the inoculation experiments of Dr. Sidney Martin with milk from tuberculous cows the shortest time in which a lesion was produced in which tubercle bacilli could be recognised was nine days, and the shortest period in which general acute tuberculosis occurred was fourteen days. The conditions of the tissues and blood serum which might determine latency were referred to, but it was pointed out that at present no definite statements could be made. Arrest and latency were not the same, the latter implied the dormant condition of a living virus with arrest the virus might be dead. Arrest in a case of fibrosis was the most favourable. Caseous lesions might break down if the capsule was destroyed. The resisting power of the individual depended upon the degree of virulence of the blood. The original infection might have been an accident due to exposure to the virus whilst the virulence of the blood was low. The importance of maintaining the general health after arrest of the disease was referred to. In some cases reinfection might be due to some local change of the nature of an accident. Regret was expressed that in connection with the latter part of the subject it had been necessary to use terms which were lacking in precision, and the hope was entertained that the discussion might bring out facts which would increase our knowledge of the conditions which determined arrest and latency.

At this stage the debate was adjourned until the next meeting.

PATHOLOGICAL SOCIETY OF LONDON.

A New Form of Steriliser and Incubator.—Adenoma of Sebaceous Glands.—Dilatation of Œsophagus.—Gall-stone impacted in Small Intestine.—Formation of Intra-abdominal Bands.—Traumatic Separation of Epiphysis of Great Trochanter.—Exhibition of Specimens.

AN ordinary meeting of this society was held on Dec. 3rd, Mr. BUTLIN, President, being in the chair.

Mr. P. T. ADAMS, introduced by Mr. TARGETT, showed a New Form of Combined Steriliser and Incubator, and described a method of direct culture upon cover-glasses by modified bacteriological methods. Some advantages of the apparatus were: 1. The facility with which it could be adapted to the several operations of the bacteriological laboratory, both as an incubator and steriliser, without change of apparatus. 2. The sterile atmosphere of the incubator presented, as nearly as possible, conditions similar to those which obtained in a living animal—namely, an atmosphere saturated with moisture and at any temperature desired or suitable to the particular micro-organism under investigation. 3. Portability and compactness, enabling accurate bacteriological work to be carried out for diagnostic or other purposes with ease and rapidity. 4. The applicability of the apparatus when dealing with small quantities of nutrient media, owing to the saturated condition of the atmosphere within the incubator. 5. The same apparatus could be used for (*a*) experiments with gaseous agents such as gases, liquids, or light, without any interference with the cultures; (*b*) bacteriological examination of air; and (*c*) anaerobic cultivation.

Dr. H. D. ROLLESTON showed a specimen of a [illegible] from the Skin of the Left Temple removed by Mr. [illegible] Dent from a man aged sixty-seven. The tumour had been there for years. Five years ago it got irritated and increased in size; a year and a half ago it had been scraped with caustic, and since then had grown more rapidly. It projected upwards above the level of the dermis, which was depressed and did not infiltrate. The epidermis covering the growth was atrophied and in one place ulcerated. The growth itself was derived from the sebaceous glands, and was of an acinous type; it was divided into lobules by well-formed fibrous tissue, and in places the interstitial substance between the masses of epithelial cells showed myxomatous change. The acini were sometimes very large and filled with epithelial débris, which by pressure had flattened the lining cells. In other parts there were masses of cells of various shapes, probably acini filled with epithelial débris. The irregular acinous arrangement might pass for the structure of rodent ulcer, which itself varied very considerably in its appearances. Dr. Rolleston discussed the relations of the growth to adenoma and carcinoma of the sebaceous glands, and on the ground that it did not infiltrate the dermis was of opinion that it should be classed as an adenoma and not as a rodent ulcer. The histological arrangement of the cells, however, was somewhat irregular and suggested a transition from an adenoma to a carcinoma, and raised the question as to the relative importance of histological structure and of anatomical relation to neighbouring tissues in determining the innocent or malignant nature of a tumour. Dr. KANTHACK regarded the specimen as one of rodent ulcer, basing his opinion upon the grounds that the [illegible]

Digitized by Google

structure was atypical, that there was some slight infiltration of neighbouring tissues, and that the appearance of the cells and arrangement of the alveoli were suggestive of malignancy.—Mr. TARGETT showed a section of a small tumour removed from the skin over the root of the left zygoma, superficial to the deep fascia; it occupied the site of a cystic growth which had been previously removed. There had been no recurrence a year after removal. Under the microscope were seen large alveoli filled with cells and well surrounded with fibrous tissue. It was covered with healthy skin which it did not infiltrate.—Mr. BOWLBY remarked that many rodent tumours did not ulcerate. The tumour shown, he agreed, had been an adenoma for many years and it had now developed a new kind of growth. Rodent ulcers probably in many cases originated in a diseased condition of the sebaceous glands.—The PRESIDENT said that both clinically and microscopically he regarded the growth as a rodent ulcer, and the long time it had existed did not militate against this. Rodent ulcer showed its malignancy chiefly by invasion and infiltration of neighbouring structures.

Dr. ROLLESTON showed a specimen of Simple Dilatation of the Œsophagus, removed from a patient under the care of Mr. Edgcombe Venning, a boy aged eight years who came of a family in which vomiting seemed to be easily set up and with difficulty controlled. The patient had had a somewhat similar attack, but recovered. The fatal illness succeeded pertussis and began with choking fits; these were succeeded by vomiting which resisted all treatment and led to a fatal termination in six weeks. The œsophagus, of normal size at its two ends, showed a marked fusiform dilatation of the intervening part. The muscular coat was hypertrophied, the mucosa was normal, and there was no sign of any organic stricture at the cardiac end. The etiology of primary dilatation of the œsophagus was briefly discussed, and it was suggested that where there was hypertrophy associated with dilatation the longitudinal coat and not both coats were enfeebled. Paralysis or inhibition of the longitudinal coat by keeping the cardiac orifice closed would explain hypertrophy of the circular coat. In this case the vomiting was apparently a neurosis connected with pertussis, and the dilatation might have been secondary and a late event in the disease.—The PRESIDENT remarked that Sir Morell Mackenzie mentioned in his work many cases of primary dilatation of the œsophagus, though he did not attempt to explain their pathology.—Dr. GOODALL saw no evidence to connect the condition described with whooping-cough.—Dr. ROLLESTON, in reply, said that whooping-cough affected especially the pneumogastric nerve, and vomiting in that disease often occurred apart from spasm of the glottis. This led him to suggest that the dilatation might result from a pneumogastric lesion.

Mr. J. HUTCHINSON, jun., related the case of a patient from whom the Calculus which he handed round had been removed. She was a woman seventy years of age, and the clinical symptoms were so clear that a positive diagnosis was made before operating. There was a previous history of biliary colic, and the obstruction had lasted three days. At the operation the intestine above the stone was greatly distended and inflamed, while the part below was firmly contracted so that the stone could not possibly move in a downward direction. Many feet intervened between the point of impaction and the cæcum. After the stone had been removed by incision through the intestinal wall the latter was sutured, and the patient made a good recovery. The calculus weighed only 120 grains, its long diameter being a little over an inch. He compared this dimension with that of Murphy's button, used in resection of the small intestine, the transverse diameter being exactly the same.—Dr. SEPTIMUS GIBBON said that he had a fatal case of this kind many years ago in his own practice. The patient was a female, and the malady was diagnosed during life, but surgery then not being so advanced as now, laparotomy was not performed. The stomach was persistently kneaded, but death resulted in nine days, and at the necropsy a gall-stone was found impacted in the duodenum.

Mr. HUTCHINSON, jun., also showed a specimen of what he believed to be a hitherto undescribed method of Formation of an Intra-abdominal Band capable of causing intestinal obstruction. In examining a dissecting-room subject a tough cord six inches in length was found to pass from the right broad ligament upwards, adhering to the great omentum at its other end. The latter was made out to be a small cyst, the hydatid of Morgagni. The remarkable elongation of its pedicle was evidently due to the excursions of the great omentum, which had dragged on the hydatid. To illustrate the varying position of the omentum, he mentioned another case in which the liver was wholly concealed by this membrane, which was attached above to the diaphragm. A somewhat similar form of intra-abdominal band originating in an insignificant anatomical structure had been recorded by Dr. Perry in the Transactions of the Pathological Society—viz., by the elongation of the appendices epiploicæ. He believed that some cases of single band causing intestinal obstruction were due to persistence of the omphalo-mesenteric vessels. It was certain that no proof of previous peritonitis could be found in many cases of obstruction by bands.—Mr. BOWLBY thought that, next to morbid adhesion of Meckel's diverticulum and of the vermiform appendix to other structures, the most common cause of bands was inflammation of the mesenteric glands of a tuberculous nature, a coil of intestine becoming adherent to the peritoneum over the site of the inflamed gland.—Dr. NEWTON PITT had seen three or four cases in which bands were traced to calcareous glands. The extreme degree of stretching which these bands would undergo was remarkable. The omentum, when adherent at its periphery, would sometimes become rolled into two or three long cords. The cord sometimes was attached to the pelvic brim over the sacrum, and some of these might be the results of inflammation started by traumatism in childhood and long since forgotten.—Dr. SEPTIMUS GIBBON commented on the absence of evidence of inflammation in many of these cases, and remarked that bands were not common causes of trouble in childhood.—Mr. TARGETT said that he had dissected the bodies of two fœtuses, and in both there were well-marked bands the remains of omphalo-meseraic vessels. They formed long thin cords extending from the attachment of the mesentery to the umbilicus. He had recently examined a specimen in which the gut had become doubled over and was adherent to its own mesentery, and so had produced obstruction by longitudinal torsion.

Mr. HUTCHINSON, jun., showed a specimen of Traumatic Separation of the Epiphysis of the Great Trochanter, given to him by Dr. Daniels of British Guiana, and obtained from a native of the latter place aged sixteen. The lad had fallen from a tree to the ground, a distance of nearly twenty feet. He survived for some eight weeks, dying from the effects of various internal injuries, including rupture of the liver. After the accident he had been able to stand and to raise the affected limb from the bed, so that a positive diagnosis was not made. In fact, this particular injury must sometimes be extremely difficult to detect, a fact illustrated by more than one of the previously recorded cases. The present made the twelfth case of which Mr. Hutchinson had found record, a striking specimen of it having been placed by him in the museum of the Royal College of Surgeons of England from a lad aged thirteen who had fallen between a train and the platform. In Dr. Daniels' case the post-mortem examination showed that the trochanter had been separated exactly at the epiphysial line, except at the lower and posterior corner, where a small portion of the diaphysis was also detached. There was a decided interval between the epiphysis and the femur, but they were connected by the periosteum, which had been stripped off the shaft for some inches whilst still retaining its attachment below. No suppuration had occurred, and evidence of commencing repair was shown in the production of new bone in the neighbourhood of the injury. The extraordinary mortality of separation of the great trochanter epiphysis was illustrated by the fact that out of the twelve cases collected by the reporter, only three appeared to have recovered, death usually occurring from shock or suppuration and pyæmia. But an obvious fallacy existed in the fact that the cases which did not suppurate or die from other injuries were rarely either diagnosed correctly or published.

The following card specimens were shown:—

Dr. H. W. MACKENZIE: Traumatic Rupture of a Bronchus leading to Pneumo-thorax.

Dr. HUGH WALSHAM: Caseating Tuberculous Tumour attached to the Cæcum.

Dr. CLAREMONT: Extensive Malignant Ulceration of Œsophagus.

Mr. TARGETT: Sebaceous Adenoma from Parotid Region.

Dr. GOODALL: Diphtheria of Œsophagus.

HUNTERIAN SOCIETY.

Vaginismus and Allied Affections.—Physiological Rest for the Lung in Phthisis.

AN ordinary meeting of this society was held on Nov. 27th at the London Institution, Mr. CHARTERS SYMONDS, the President, being in the chair.

Mr. B. Byrne, Mr. J. McClymont, Mr. R. Jones, and Mr. H. Blandford were elected Fellows of the society.

Dr. HERMAN read a paper on Vaginismus and Allied Affections. He said that the subject of his paper was those diseases which had as their chief symptom "dyspareunia"—that is, pain and difficulty in sexual intercourse. He divided these into three classes — viz.: 1. Simple smallness of the vaginal orifice. In this there was no visible sign of disease; gentle examination did not cause pain; the patient was quite well till marriage, and the trouble dated from then. The treatment was to enlarge the vaginal orifice. This might be done (*a*) by gradual dilatation, (*b*) by rapid dilatation, and (*c*) by incision. The last method was the best. 2. Diseases of the vulva such as to make it tender. Most of these caused the patient to complain of something else besides dyspareunia. The one of which dyspareunia was the first and chief symptom was that to which the late Professor Breisky of Vienna had given the name of "Kraurosis Vulvæ." Kraurosis meant shrinking. It was characterised by progressive contraction and tenderness of the vaginal orifice. Mr. Lawson Tait had described a condition having similar features, but in addition patches of purple to brown discolouration. Mr. Tait held that this was an early stage of the condition described by Breisky; but German writers denied this. In some of the cases of kraurosis described by German writers red or purple discolouration was present. He (Dr. Herman) had seen purple tender spots on the vulva get well without leaving any shrinking or tenderness behind; he had also seen purple spots, like those in the condition described by Mr Tait, but which were not at all tender. He therefore thought Mr. Tait was right in thinking that his cases were examples of the disease described by Breisky, but that the colouration was not an essential part of the disease. Kraurosis came on towards the climacteric age. Sometimes it followed oöphorectomy. It was often associated with vaginitis, and with itching and burning of the vulva without contact. The best treatment was the use of sedative vaginal injections (such as lead or boric acid) and dusting the vulva with sedative powder (such as boric acid or dermatol). By such treatment the patient could usually be placed in comfort if not married. If such treatment failed, or if the patient were a married woman, the only treatment was to excise the tender and shrunken mucous surface. He had done this in one case with success. 3. Vaginismus. This was a nervous disease, attended with hyperæsthesia of the vulva and spasmodic contraction of the levator ani and other muscles, and often associated with dysmenorrhœa and hyperæsthesia of the rectum. This disease was generally discovered at marriage, but might suddenly appear after years of healthy married life. Sometimes it was cured by curing dysmenorrhœa. Otherwise genuine vaginismus was incurable, even by childbirth, though in the course of years it got somewhat less. It was sometimes difficult to distinguish genuine vaginismus from mere smallness of the vaginal orifice in a sensitive patient. In a doubtful case the best treatment was to give the patient the benefit of the doubt and enlarge the vaginal orifice by operation. Dr. Herman exhibited a drawing of a case of kraurosis vulvæ.—Mr. STEVENS remarked on the rarity of the two affections, and asked if herpes vulvæ might not be the actual lesion in some cases.—Dr. F. J. SMITH thought that kraurosis vulvæ was a trophoneurosis allied to morphœa.—Mr. COTMAN thought the male organ was usually at fault.—The PRESIDENT mentioned leucoplakia of the tongue and a fibrous condition of the male prepuce as probably pathologically identical with kraurosis vulvæ.—Dr. SHADWELL also discussed the condition, and Dr. HERMAN replied.

Dr. ARNOLD CHAPLIN then read a paper on Physiological Rest for the Lung in Phthisis. The paper was really a plea for non-intervention by mechanical means in cases of pleural effusion, whether of serum or pus, where the underlying lung was the seat of tuberculous processes, and was based on clinical experience of some two or three cases in which, after aspiration, the patient had rapidly gone downhill. He also advocated artificial restraint of the movements of a tuberculous lung.—The PRESIDENT said he had actually been asked by the late Dr. Mahomed to produce an artificial pneumothorax in a case of phthisis.—Mr. OPENSHAW remarked that the late Dr. Sutton agreed with Dr. Chaplin in objecting to aspiration in such cases.—Mr. HUMPHREYS thought that there were two opposite schools of opinion, the one advocating free movement in affected lungs, the other forbidding movement.—Sir H. BEEVOR thought the question a very important one, but it involved considerations of very opposite nature, and he was inclined to the belief that movement was only one factor, and possibly a small one, in the advance of phthisis.—Mr. COTMAN, Mr. STEVENS, Dr. J. H. SEQUEIRA, and Dr. F. J. SMITH also discussed the paper, and Dr. CHAPLIN replied.

HARVEIAN SOCIETY OF LONDON.

Some Forms of Iritis.

A MEETING of this society took place on Nov. 21st, the President, Sir JOHN WILLIAMS, Bart., being in the chair.

Mr. HENRY JULER read a paper on Some Forms of Iritis. The recognition of iritis, the pathological processes which ensue at the time and subsequently, and the indications for treatment depend, Mr. Juler pointed out, upon an exact knowledge of the anatomy and physiology of the eyeball. He emphasised the value of knowing the arrangement of the bloodvessels, the circulatory course of the lymph, and the muscular apparatus. Excluding the traumatic and sympathetic forms, he divided iritis into two main groups—the plastic and serous varieties. Dismissing the latter with a few remarks, Mr. Juler entered more fully into the causes of plastic iritis. He considered all kinds arising spontaneously to be due to some dyscrasia, whether it be gout, rheumatism, syphilis, tuberculosis, or any other constitutional disease. The uric acid diathesis could exist, in his opinion, and give rise to this affection without any other evidence of gout, and it was very necessary to examine the urine and make a quantitative estimation of the nitrogenous excreta. He then briefly pointed out certain local signs by which the different varieties could be differentiated, but emphasised, nevertheless, the importance of examining the patient as to his general health, so that the actual cause might be discovered and properly treated. In speaking of treatment Mr. Juler was of opinion that medical practitioners were hardly aware of the severity of the affection and paid insufficient heed to the fundamental treatment of all inflammations—rest. He could not lay enough stress upon the vital importance of adopting both general and local rest. The latter was best secured by the instillation of sulphate of atropine drops, which paralysed the sphincter pupillæ and ciliary muscles. It was a drug of the greatest value; besides giving rest to the intrinsic muscles of the eye, it prevented, or, if they were present, broke down, iritic adhesions, and was also a local sedative. To relieve pain by the use of several leeches and to give sleep by administering opium or bromidia were useful adjuncts. In gouty subjects the exhibition of hot-air baths, attention to diet and habits, and depletion were essentials. Mercury in syphilitic iritis, salicylate of soda in rheumatic iritis, and such like constitutional treatment were not to be forgotten.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Latah.

A GENERAL meeting of this association was held at the society's rooms, 11, Chandos-street, Cavendish-square, on Nov. 21st, under the presidency of Dr. NICOLSON.

This was the first statutory meeting since the incorporation of the association. Before beginning the ordinary business the PRESIDENT referred to the death of Dr. Jamieson of Aberdeen, the oldest superintendent of an asylum in Scotland, who had during the previous week died at the ripe age of seventy-seven. Although but little known to the junior members of the specialty, yet in his day he carried on a great work at Aberdeen when the methods of dealing with insanity were very backward compared with those at present in vogue, while his writings on insanity were very well worth

Digitized by Google

perusal now in the light of the best work that had been done in recent years.

Dr. GILMORE ELLIS then read a paper on Latah, a disease which affects the natives of the Malay Peninsula. It seemed closely allied to the hysterical or hypnotic condition, but was yet essentially different from them. Many of the cases seemed to be markedly of an imitative character. The onset of the disease was due to the person being startled by some object of terror or by being suddenly excited; the condition varied in degree, and, in his experience, it did not incapacitate the person affected from ordinary work. The Malays, no doubt, displayed some simplicity of mind which rendered them susceptible to external influences and apt to be thrown by them into a state of profound agitation, yet education had no effect on the progress of the disease, for latah was just as frequent at the present day, when there are British-taught schools throughout the peninsula, as it was forty or sixty years ago. The disease was not of the nature of insanity in any way, for persons suffering from latah carried on their work like other people and were very able, as far as Malays go. The histories of some cases were given, in which the imitative character of latah was fully shown.—A discussion followed, in which the PRESIDENT, Dr. COOKE, Dr. MERCIER, Dr. MICKLE, Dr. SEYMOUR TUKE, Mr. RICHARDS, and Dr. FLETCHER BEACH took part.

Six candidates, including one lady, were elected ordinary members of the association.

LIVERPOOL MEDICAL INSTITUTION.

Vyrnwy Drinking-water.—Pityriasis Rubra.—Some Therapeutic Actions of Oxygen.—A Life Table for Liverpool.

AN ordinary meeting of this society was held on Nov. 28th, the President, Mr. CHAUNCY PUZEY, being in the chair.

Dr. HOPE asked a question of which he had given notice, as to whether any member of the institution had had experience of the alleged deleterious effects from the use of Vyrnwy drinking-water. He stated that so far as his investigations enabled him to judge, the one or two allegations concerning illnesses due to the use of the water were absolutely destitute of any foundation; and in one of them the Vyrnwy water was not supplied to the house in question at the time the alleged mischief from its use arose. A short discussion ensued, but no one had any adverse comment to make in reply to the question.

Dr. STOPFORD TAYLOR showed a case of Pityriasis Rubra. It was the patient's second attack. The skin remained quite free from any eruption during the interval. The first attack occurred in 1892 and was secondary to a psoriasis of many years' duration. The patient was admitted into the Skin Hospital in March this year. The treatment adopted was prolonged daily warm baths of several hours' duration, followed by smearing with an ointment of glycerine of lead and vaseline. Five months later, the scaling having ceased and the redness still remaining, an ointment of chrysophanic acid was rubbed in night and morning, and the patient was allowed to get up. The effect of this was to cause the rapid disappearance of the redness, except in a few isolated patches; these were painted with pure liquid tar and finally cleared. Quinine was given internally almost the whole time. The patient is now perfectly well, the skin being pale, smooth, and soft.—Mr. RICHMOND LEIGH asked Dr. Taylor if he had found pityriasis rubra especially fatal. In a table of some twenty-two cases published in the *Journal of Dermatology* by Dr. Stephen Mackenzie there were three deaths. Half of the cases were primary, and one of the deaths was in a case secondary to pemphigus foliaceus, a most fatal disease.—Dr. CARTER and Dr. ALEXANDER made remarks on this case.

Dr. C. J. MACALISTER related two cases in which Oxygen had proved very serviceable. One of them was a case of Uræmic Coma associated with lividity, in which almost at once consciousness was gained when the oxygen was administered. The other was a case of Morphia Poisoning where artificial respiration was necessary until the gas was given, when the respiratory function was restored and the cyanosis of the face, lips, and extremities was greatly relieved. In both cases—an account of which we print in this week's issue—recovery, it will be seen, was complete.

A paper was brought forward by Dr. HUGH JONES and Dr. S. G. MOORE entitled "A Life Table for Liverpool." After describing the method adopted in the construction of the table, it was shown that a considerable saving of life had been effected since the first life table was prepared by Dr. Farr in 1843. A reduction had taken place in the death-rate at all age groups, with a consequent higher expectation of life at all ages. The life table based upon the figures for 1881–90 showed that the expectation of life at birth was 34·2 years, compared with 41·3 years for England, 34·7 for Manchester, and 35·2 for Glasgow. The diminished mortality had resulted in a considerable addition to the useful years of life—i.e., between twenty and sixty-five years—amounting to 2500 years of life per 1000 births. It was further shown that the chief incidence of the excessive mortality in Liverpool was at the earlier ages, though, compared with England and Wales, the mortality was high at each age period. It was pointed out that the enlargement of the city boundaries, by which a large suburban area is being absorbed by the city, would result in an apparent diminution in the death-rate, but that this diminution would not of necessity imply any improvement in the sanitary condition of the city or in the vitality of the inhabitants.—Dr. HOPE, medical officer of health, complimented Dr. Hugh Jones and Dr. Moore on the pains taken in constructing the life table, and in criticising it indicated directions in which elaboration was necessary before the table would add materially to knowledge upon the subject. Notwithstanding that the duration of life was shorter amongst dwellers in cities than amongst dwellers in rural districts, insurance companies drew no distinction, a circumstance which suggested that it was not among the insuring and thrifty class that the mortality was excessive, but amongst the vast labouring population. The inclusion or exclusion of rural areas in urban registration districts was a most important factor in modifying death-rates of cities.

KIDDERMINSTER MEDICAL SOCIETY

Appendicitis.—Injury to Shoulder.—Congenital Contraction of Fingers.—Piece of granite in Eye.—Poisoning by Carbonic Oxide.—Exhibition of Specimens.

A MEETING of the above society was held on Nov. 22nd, Mr. W. MOORE, President, being in the chair.

Mr. J. L. STRETTON read notes of four cases. Case 1 was one of Appendicitis. The patient was a youth aged nineteen years who had suffered from occasional attacks of colic which were never severe. He had severe pain in the abdomen when he got up one morning, but he was able to go to work; the pain subsided and he ate a very large dinner of pork and bread. Towards evening the pain returned in greater intensity. Dr. Oldham was called in on the following morning and found him complaining of intense pain all over the abdomen, which was distended and tympanitic. Six grains of calomel were given and fomentations applied. The next morning he was still in pain and had not slept. The calomel had not acted. An enema was administered without result. The temperature was 103° F. and the pulse was 112. He passed flatus during the day and vomited a large quantity of bile in the evening. Dr. Oldham took him to hospital about 10 P.M. On admission he complained of abdominal pain and lay on his back; the abdomen was swollen and tense and did not move on respiration. There was a distinct fulness in the right iliac region. Under ether an incision was made in the middle line. Some stained fluid escaped from the abdomen and the coils of small intestine were covered with lymph. The appendix was found to be perforated near the base; it was ligatured and removed and the stump sutured. The abdomen was flushed with hot boracic lotion and a drainage-tube inserted. One-drachm doses of hot water were administered, but as this caused vomiting it was stopped. The patient died thirty-six hours after the operation, immediately following a copious vomit. A limited necropsy disclosed a quantity of pus in the right iliac region. The appendix removed contained a fæcal concretion. Case 2 was that of a woman aged forty years who was admitted to hospital suffering from an Injury to the Left Shoulder, which took place five weeks previously from falling down fourteen steps. She was under the impression that her shoulder was dislocated and was unable to move the limb. Examination revealed a sharp prominence beneath the outer end of the

Digitized by Google

clavicle and that the shoulder-joint was fixed. Under an anæsthetic the arm was forcibly manipulated, several adhesions were broken down, allowing free movement at the joint, and the bone was refractured but could not be brought into position. An incision was made over the prominence and the fracture exposed; it ran obliquely downwards and outwards through the lesser tuberosity, the lower portion of which formed the sharp projection above noted. There was so much thickening that it was necessary to remove this projection with bone forceps before the bones could be brought into position. The wound was brought together with catgut sutures and dressed with cyanide gauze. A pad was placed in the axilla and the arm bandaged to the chest, a shoulder cap being applied outside. The dressings were removed in a week, showing primary union. Passive movements were commenced the following week, with daily increasing massage, and the patient was discharged five weeks after admission with a useful arm. Case 3 was that of a child aged six weeks with congenital Contraction affecting the index-finger of the right and the middle finger of the left hand, and resembling in appearance Dupuytren's disease. Case 4 was that of a man aged twenty-four years with a Piece of Granite in the Anterior Chamber of the Eye. He had had an accident four years ago; a stone flew up into the eye, which affected his sight; the present injury was sustained about a month ago. A piece of granite about the size of a split pea was distinctly visible in the anterior chamber which moved with the position of the head. The scar on the cornea was in the line of vision, and the pupil was contracted and irregular owing to complete posterior synechiæ probably due to the former accident, and it was this condition which had prevented the sharp piece of granite from slipping into the deeper structures. The patient could barely distinguish light, and the eye had an unhealthy appearance.

Mr. W. HODGSON MOORE described two cases. Case 1 was one of Carbonic Oxide Poisoning. The victim was a young, healthy bricklayer who was at work pointing the defects in a retort which had not been used for some time. His mate left him for a few minutes and found him unconscious on his return. When seen by Mr. Moore he was quite dead, and all efforts to restore animation were unavailing. The only peculiarity noticeable about the body was the salmon-pink colour of the cheeks, which extended to the chest and arms; on raising the legs a suffused appearance of the face was produced. A necropsy was made two days later; the pink colour was still quite distinct, and the muscles when cut into exhibited a bright colour. The blood was fluid and very bright; with a 30 per cent. solution of caustic soda, red stringy clots were produced. The organs of the body were healthy, but all exhibited the peculiar colour. The gas authorities denied the possibility of carbonic oxide poisoning, but Mr. J. L. Stretton, who attended the necropsy on their behalf, strongly supported Mr. Moore's view. It is probable that in scraping some of the decayed places, or in moving some of the rubbish admitted to be on the floor of the retort, the man liberated some of the gas, a very small quantity of which produces a fatal result. Case 2 was that of a man aged twenty-four years whose Brain at the necropsy showed Multiple Tumours generally distributed, probably malignant, and who had been admitted about ten days previously with severe headache. He was too ill to give an exact history, but it was ascertained that the illness commenced five weeks previously with fits (Jacksonian epilepsy on the left side) and had got worse. He had been ill at times all his life, and his right side had been weak. He had had "lumps" in the neck for four years. He had double optic neuritis and considerable incoördination. No remedies had any effect, and he died comatose.

Mr. DAVIES showed the Spleen and Internal Organs from a case of Leucocythæmia in a female aged ten years admitted under the care of Mr. J. L. Stretton in a moribund state though she had only been ill for seven days.

Mr. DAVIES read a paper entitled "Rough Notes on Clinical Treatment."

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Three Cases of Hernia with Unusual Complications.—The Diagnosis of Hystero-Epilepsy.

A MEETING of this society was held on Nov. 26th, DR. ADOLPH BRONNER, President, being in the chair.

DR. HOLTBURNE gave a demonstration of microscopical specimens illustrating—(1) Typhoid Fever Bacilli [illegible] Spleen and in Ulcer of the Intestine; (2) the deposit of iron salts in the kidney and in the liver in cases of Pernicious Anæmia and in Lead Poisoning; and (3) [illegible] droma of the Cervix Uteri.

Dr. S. LODGE, jun., showed two patients suffering from Hemianopia.

Dr. CAMPBELL showed a case of Progressive Muscular Atrophy in a man. There was wasting of the muscles of the arms and hands; the leg muscles were wasted; the knee-jerks were brisk. The differential diagnosis of the case was discussed. — Dr. GOYDER, Dr. EVANS, and Dr. RAMSDEN made remarks, and Dr. CAMPBELL replied.

Dr. A. BRONNER showed two patients on whom he had operated for Mastoid Disease, and advocated operation in cases of chronic otorrhœa with mastoid symptoms.

Mr. HORROCKS read a paper on three cases of Hernia with Unusual Complications. In the first case the cause of the trouble was found at the operation to be a tumour in the mesentery, which blocked the inguinal canal and prevented the reduction of the hernia; in the second case a half twist of the mesentery was found; and in the third case the cæcum formed part of the sac wall.

Dr. MAJOR read a paper on the Diagnosis of Hystero-Epilepsy, and the treatment of the Paroxysms. The essential diagnosis between epilepsy and hysteroid attacks was considered, the involuntary passage of urine, biting of the tongue, and the formation of petechiæ pointing to true epilepsy. The treatment recommended for the hysteroepileptic attacks was—(1) to compress the nose and mouth for thirty seconds; (2) strong faradaism; and (3) apomorphine hypodermically (one-twelfth of a grain).—Dr. CARTER laid stress on insensibility as pointing to true epilepsy.—Dr. MANTLE would look upon fever as indicative of epilepsy.—Mr. HORROCKS and Dr. FARRAR made remarks, and Dr. MAJOR replied.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on Nov. 14th, Dr. DRUMMOND, President, being in the chair.

Mr. A. E. MORISON showed a patient aged thirty-one years who had been successfully trephined for Jacksonian Epilepsy. The symptoms commenced in September, 1894, with loss of power in one arm up to the shoulder and some weakness in one leg. He was first seen in January, 1895, and he then complained of headache over the face of Rolando, coming on before the fits and lasting six or seven days after. His vision was impaired and he had well-marked double optic neuritis. His arm and leg were feeble. The reflexes were exaggerated. He had been previously trephined on the right side without benefit. Another operation being deemed advisable, the trephine was first applied between the arm and leg centres and there the brain pulsated. Another disc of bone was removed over the arm and face centres. Here the bone was firmly adherent to the dura mater, and there was no pulsation round this spot; the bone was chiselled away till a pulsating ring surrounded the non-pulsatile portion. An escape of subarachnoid collection of fluid was emptied, and the wound was entirely closed without drainage. The patient's recovery was uneventful, the fits and optic neuritis disappearing and his vision being so little impaired that he could read ordinary print. In connexion with this case Mr. Morison showed on the skull a simple and satisfactory method of mapping out the fissure of Rolando.

Dr. GOWANS showed: 1. A patient suffering from myxœdema whose patella had been wired for recent fracture, and who had been exhibited at this society many years ago as a rare, though a well-marked, case of myxœdema occurring in a man. He had undergone at intervals irregular treatment by thyroid feeding with improvement, though the evidences of myxœdema were still distinct. The result of wiring the fractured patella was quite perfect. 2. A patient twenty-eight years of age who had recovered after Removal of a Haemorrhagic Ovarian Cyst. 3. A patient recovered from an Operation for Ectopic Gestation. She was a married woman, aged seven years of age and the mother of [illegible] last born three years before her illness. [illegible] in March, 1895. Early in May, [illegible] she had vaginal hæmorrhage [illegible] more or less hæmorrhagic [illegible]

Digitized by Google

fainted and became collapsed. On May 28th Dr. Gowans saw her and found a tumour in the middle line in front of the lower abdomen. She was so ill that no operation could be undertaken then; but in the first week of June the abdomen was opened and emptied of blood and clot in which floated a three months' fœtus. The sac was drawn out and cut off, and the cavity left plugged with gauze and drained by a tube. The tube was removed in forty-eight and the gauze in seventy-two hours. The patient, though very ill for a few days, is now in perfect health.

Mr. PAGE showed: 1. A man who had been brought before the society a month previously with Epithelioma of the Penis, Scrotum, and Inguinal Glands. The whole of these organs were now removed, and the wound was almost healed, but it was doubtful if all disease had been eradicated. 2. A patient aged six years successfully operated upon for an Ovarian Tumour (fibro-sarcoma) weighing nine and three-quarter pounds. So far as he could ascertain, this was the youngest child who had recovered after removal of a sarcomatous ovary.

Dr. HUME showed several patients on whom the operation for Radical Cure of Inguinal Hernia had been performed. Eight cases were operated on by Halstead's method; there were four recurrences. Two were treated by Macewen's method; one recurred. Nine were treated by the ordinary operation (removal of sac and stitching canal and pillars of ring); all recovered, but two wore a truss.

Reviews and Notices of Books.

Twentieth Century Practice. Vol. II.: *Nutritive Disorders.* Edited by THOMAS L. STEDMAN, M.D., New York City. London: Sampson Low, Marston, and Co. 1895.

THE second volume of the above work deals with Nutritive Disorders. Sir Dyce Duckworth writes the first article on Addison's Disease and other Diseases of the Adrenal Bodies. In some thirty pages a succinct summary of our present knowledge of the subject is given by one who seems from an early period of his medical career to have devoted special attention to it. Sir Dyce Duckworth supports the generally accepted view of the tuberculous nature of the disease, which usually attacks the adrenals when they are associated with the striking constitutional and local evidences of the disorder to which Addison of Guy's Hospital was the first to call attention. The various theories promulgated to account for the disease are critically considered, and the subject is brought up to date by some reference to the researches of Oliver and Schäfer on the influence upon the blood-pressure of dogs of the intravenous injection of an adrenal extract.

The article on Diabetes Mellitus is by Dr Carl von Noorden of Frankfort-on-the-Maine. The rapid progress in our knowledge of the disease since the date of Claude Bernard's experiments is sketched and particular attention drawn to the glycosuria of phloridzin poisoning and the diabetes induced by removal of the pancreas. The lesson he draws from phloridzin glycosuria is that the old notion that diabetes may be a disease of the kidneys in some instances, while as yet unproved, may have some truth in it. His general study of the subject inclines him to define diabetes as "a disease in which the capacity of the organism for burning up grape sugar is morbidly depressed," but he hesitates to adopt this definition without reservation, as there is not yet certain evidence that it exhaustively explains the condition actually present. The whole subject is treated in a thoroughly satisfactory manner, both from a theoretical and practical point of view. He regards the excretion of oxybutyric acid of the gravest prognostic import as rendering the speedy onset of coma very probable. In the treatment of the coma when it actually supervenes he confesses our practical helplessness, but recommends a further trial of the intravenous injection of a 0·6 per cent. salt solution, followed by injections of camphor and ether to combat the cardiac weakness which is always present.

Dr. T. J. Maclagan of London writes the article on Rheumatism, and has produced a practical essay of much value. He contrasts the former and present duration of acute attacks of the disease, and tells the story of his happy surmise that the bane and antidote might be found side by side, the healing salix near the swampy rheum. While pointing out important arguments in favour of the lactic acid theory of the disease, and rejecting after discussion the neurotic he adopts, as is well known, the miasmatic theory, and writes at some length of the analogies between ague and rheumatism and between quinine and salicin. He endeavours to establish, and argues strongly in favour of the thesis, that the local inflammation is limited in the joints almost entirely to such fibrous and serous textures as are associated with active movement and in the heart to the left side. He believes that the comparative immunity of the right side of the heart from destructive rheumatic lesions is due, like the immunity of the smaller joints, to the comparatively small amount of labour which is thrown upon the right as compared with the left heart. We naturally turn with interest to learn Dr. Maclagan's views on the salicylic treatment of rheumatism, and learn that the points he especially emphasises are that the drug should be given in full and frequent doses till the temperature is normal and the pain gone, and that it should be continued in smaller doses for ten days after acute symptoms have ceased. The comparative failure of the salicyl compounds to prevent heart complications he attributes to the activity of that organ as compared with the quiescence of the joints under treatment at the same time, but cogently argues that the other advantages gained by curtailing the duration of the disease and reducing temperature cannot be without favourable influence on cardiac complications. The article concludes with remarks upon the relation of rheumatism to chorea, in which the author is led to the general conclusion that rheumatism is essentially a disease of the motor apparatus, while chorea is essentially a disease of the motor centres. and considers this to be the clue to the explanation of the relation of the two diseases.

Dr. Henry M. Lyman of Chicago contributes the article on Gout, and in 180 pages treats this extensive subject historically, critically, scientifically, and practically. The therapeutic section of his essay is especially full, and due emphasis is given to the debilitated conditions acquired and inherited which foster the defective metabolism which lies at the foundation of gout. Few subjects are of such all-embracing interest to the physician as this protean malady. Dr. Lyman does full justice to his collaborateurs in unravelling the mystery of the disease, and speaks more appreciatively than many of the labours of Dr. Haig in this sphere. It is, perhaps, unavoidable in the close consideration of the uric acid dyscrasia that great emphasis should be laid upon the predominant *rôle* played by the imperfect metamorphosis of the nitrogenous compounds, but it is better that such emphasis should be too great than too little. The visceral complications of the disorder are adequately considered, and their treatment is indicated in a way to be of practical guidance to the practitioner.

Dr. Archibald E. Garrod of London contributes a discriminating article on Arthritis Deformans, evidently the result of much thought and observation. He prefers Virchow's term as implying no theory of the disease. According to Landré Beauvais precedence in the description of the disease, he does justice to the long overlooked services of Dr. Haygarth of Bath as a pioneer in the delineation of this ailment. The morbid anatomy adopted is chiefly that of Cornil and Ranvier. In the clinical section of the essay most space is naturally given to the multiple variety chiefly seen among middle-aged and elderly women, although not confined to these. The author inclines to the adoption of the neurotic

Digitized by Google

dystrophic theory of the disease, while he admits the very considerable prevalence of a gouty and rheumatic history in many cases, either in the patients or in their families. Heberden's nodes receive separate treatment, as does the arthritis deformans of children. There is also a section devoted to joint lesions resembling those of arthritis deformans, such as the joint affections found in association with locomotor ataxia, syringo-myelia, and hæmophilia. In the treatment of this condition the importance of a nutritious dietary, tonics, hygienic surroundings, and patience are wisely dwelt upon. The only point in the entire article which we should feel disposed to disagree with is the consideration, together with this well-defined clinical entity, of such conditions as the articular disorganisation met with as a result of gonorrhœal infection, and we question very much the correctness of the supposition that the only difference between the dystrophic joint diseases of central nervous origin and those of arthritis deformans, or rheumatoid arthritis, is one of degree and not of kind. Rheumatoid arthritis is a term which commends itself to us, not because of an implied rheumatic origin, but because the joint lesions resemble more in their duration and degree those of chronic rheumatism than of the more destructive and more distorting lesions due to central nervous lesions and gonorrhœal pyæmia.

Diseases of the Muscles are considered by Dr. Dujardin-Beaumetz of Paris. Muscular disease as secondary to changes in the nervous system are alluded to with necessary brevity, as belonging to another section of this work, and the article deals mainly with acute and chronic myositides properly so called. Infectious (suppurative) myositis is well described, and in the sustaining and antiseptic treatment of muscular inflammation the author speaks very highly of the tonic and stimulating properties of kola nut and of the antiseptic virtues of a soluble naphthol (asaprol) introduced by himself and Stackler. An interesting clinical description of syphilitic contracture is included in the article, and its amenability to the usual specific treatment is mentioned.

The last article in this volume is concerned with the Nature and Treatment of Obesity, and its excellence is vouched for by its authorship. Professor Oertel of Munich, so well known by his works on the dietetic and mechanical treatment of diseases of the heart and circulation, has, in the essay before us, condensed results of much thought and observation. The plethoric, anæmic, and hydræmic forms of obesity are dealt with, and the interesting question of plethora discussed with rational precision. As was to be expected from the importance of the subject in relation to accumulation of fat, and from the deservedly high authority of the writer, the anatomical and clinical effects of obesity upon the organs of circulation and its relation to arterio-sclerosis are treated somewhat in detail. Judicious advice as to the prophylaxis and treatment of the condition are also to be found in this valuable essay, which Professor Oertel concludes with these weighty words: "The great number of deaths arising from fatty heart, heart paralysis, arterio-sclerosis, and dropsy are not ordinarily to be regarded as unavoidable consequences of disease; but, for the most part, are the result of conditions which the patient has brought upon himself, and which he can avert by the use of sure means and methods, even in the advanced stages, if he has the will-power to do so. In this regard he is the master of his own health."

Clinical Lectures on Diseases of the Nervous System. By W. R. GOWERS, M.D., F.R.S. London: J. & A. Churchill. 1895.

WHEN a few years ago Dr. Gowers resigned his appointment at a teaching hospital it was felt that so long as he continued his weekly afternoon of out-patient teaching at the National Hospital for the Paraly and Epileptic, Queen-square, there would still be opportunity for hearing at his best one of those who h taken perhaps the largest share in systematising a extending our knowledge of nervous diseases. But rolled on and even the weekly out-patient afternoon ha yield to the exigencies of other claims. This volume, ho ever, is evidence of the fact that something has arise take its place, for we read on the title page that th lectures were delivered at Queen-square, and we are gl learn that one whose teaching in nervous diseases has alr been characterised by vigour and originality can st listened to at that hospital, which is more particular associated with his neurological work.

In this volume there are twenty lectures in all, arran apparently without system. The first deals with the pr ciples of diagnosis of nervous diseases, and the second m mistaken diagnosis. The other subjects are more sp comprising bulbar and facial palsies, acute ataxic myelitis, locomotor ataxy, &c. All the lectures are of m interesting, but they differ in their degree of interest. have read them all with pleasure, but those which seem to be almost models of what such lectures should be are lectures on bulbar and facial paralysis. The book will ap we believe, to those whose knowledge of nervous dise profound, and it will interest those whose knowledge slight. But it is also such a book as will stimulate perhaps inspire those who are only on the threshold vast storehouse of neurological knowledge.

An Atlas of Ophthalmoscopy, with an Introduction to the Use of the Ophthalmoscope. By Dr. O. HAAB, Profes Ophthalmology, University of Zurich. Translated edited by ERNEST CLARKE, M.D., B.S. Lond. Lo Baillière, Tindall, and COX. 1895.

THE use of the ophthalmoscope is so uniformly tau all our schools that it may be presumed that those who to possess this volume have already made themselves fam with the use of the instrument, which, indeed, can on taught practically; but those who have overcome initial difficulties will find the volume before us very use

The introduction, occupying fifty-five pages, supplie description and explanation of the several errors of refra and of the modes in which the eye may be examined is written, although very briefly, in an easily intelli manner. The expense of the larger works illustra the diseases of the fundus of the eye is almost prohibi to the student, but the chief affections can be studied in the sixty-three plates—some of which contain two, or four, subjects—at the cost of a few shillings. The dis of disease selected to be illustrated and the special va depicted are those that are most common and are likely most serviceable to the practitioner as types. One of the the drawings seem to us to be rather exaggerated, as in case of Fig. A of Plate 3, representing the normal retina a deeply pigmented eye, but the great majority ha evidently been drawn from life and are sufficiently ac recognisable. Dr. Ernest Clarke may be congratulated having translated a very useful work.

Functional and Organic Diseases of the Stomach. By Sidn MARTIN, M.D., F.R.S., F.R.C.P., Assistant Physician University College Hospital, &c. 500 pp., 57 Illustrations Young J. Pentland, Edinburgh and London. 1895.

IN no branch of clinical medicine has more rapid develo ment taken place during the last few years than in t application of methods of chemical research to the examin tion of the various secretions of the body, and to the bloo and Dr. Sidney Martin's book fully justifies its existence fulness and clearness with which it treats of approved

Digitized by Google

chemical methods and indicates how they may be carried out in investigating cases of gastric disturbance with comparatively little trouble by the busy practitioner.

Commencing with a careful account of the anatomy of the stomach and a full description of the processes of normal digestion, so far as those take place in the stomach, he passes on to the digestibility of various articles of food and the influence of condiments, stimulants, and other accessories. Dr. Martin inserts, chiefly as quotations from other authors, very serious indictments against wine, beer, tea, coffee, and tobacco, which are hardly supported by experience. The chapter on Indigestion of Food so far as it deals with gastric digestion is very full, but it is to be regretted that Dr. Martin did not in this chapter enlarge his scope and take a wider view of the digestive process. As it is, by omitting the part played by the liver, pancreas, and intestines, he has presented us with a part only of the picture. The latter half of the book deals with the organic and functional diseases of the stomach and is characterised by careful study and lucid description. The chapters on Ulcer of the Stomach and Cancer of the Stomach are particularly to be commended. They are full and accurate without being diffuse or tedious, and embody the latest knowledge on the subject. The book is well printed and illustrated, and will take a high place among those monographs on the subject—such as Habershon's and Ewald's—which are standard books of study and reference respecting a group of diseases from which few persons altogether escape.

Möller's Operative Veterinary Surgery. Translated and edited from the second enlarged and improved edition of 1894 by J. A. W. DOLLAR, M.R.C.V.S. Edinburgh: David Douglas. 1895. Price 21*s.*

THE title of this translation is incorrect, as the work is not on *operative* but on *special* veterinary surgery, as indicated in the German book, which is designated "Lehrbuch der Speciellen Chirurgie für Thieraerzte," and which really forms the second volume of a work on veterinary surgery, the first being devoted to general surgery. There is also an error with regard to the date of publication of the German edition, which is given on the title-page of the translation as 1894, whereas it was issued at Stuttgart in 1893. The volume really deals with a description of certain surgical diseases and accidents to which some of the domestic animals are liable, together with their treatment and any operative procedure that may be necessary for their cure; it is not in any respect a treatise on operative surgery, as not a tithe of the operations performed on animals are alluded to, while in many of the diseases described operative interference is either not demanded or is quite impossible. The woodcuts are generally good, as illustrating some of the diseases, accidents, or deformities treated of, but the bibliography is lamentably deficient, as happens so frequently in Continental veterinary works.

Veterinary surgeons in this country evidently have little to learn from their German *confrères* if this work is to be taken as an example of their surgery, and it is somewhat difficult to understand why it was considered necessary to attempt this translation.

CHRISTMAS BOOKS.

IT is nowadays the fashion to sneer at Christmas, to say its observance was invented by Dickens and is no longer the thing for modern days; still children, and even some elders, welcome it, and the publishing trade make a special feature of books of adventure, ghost stories, &c., in honour of the "joyfullest feast."

The Christmas ghost has rather gone out of late years, so we are glad to see it revived in the Christmas number of *Chapman's Magazine*. Mr. Arthur Machen contributes a creepy tale wherein the Red Hand, the "mano in fico" (not used as Mr. Hardy's Arabella used the fragment of pig), the evil eye, prehistoric gold-workers, and a murder are all worked into a harmonious whole. In "The Story of a Ghost" Miss Hunt has hit upon a really original kind of spectre. There have been bodiless ghosts of all kinds. There is the warm-blooded vampire of Eastern Europe—i.e., a body animated by a fiend—there is the still worse ghost with a decomposing body, of Iceland, and the Homeric ghost who, though his body had been burned, managed to drink blood, but none of these has the indefinite horror of Miss Hunt's creation. Her portrait of a medical man is good, a thing rare in fiction.

Messrs. Blackie and Son have sent us a large quantity of books for boys. *Hallowe'en Ahoy*, by Hugh St. Leger, is a story of the sea with all the requisite setting of a derelict ship, a storm, a wreck, and castaway life on the Crozet Islands. There is a ghost too.

Two Gallant Rebels, by Edgar Pickering, is a tale of the times of the great French Revolution. Claude Oglander and Rupert Ogilvie are shipwrecked upon the coast of France, join the Vendean army, take part in the celebrated attack upon Thouars, and are finally condemned to the guillotine in Nantes. The account of their escape is thrilling, but does not bear the same air of probability with which that master story-teller Dr. Neale treated a similar incident occurring in Paris in his tale "Duchenier."

His First Kangaroo, by Arthur Ferres, is a good book of Australian life for boys. There is a thrilling fight with bushrangers and plenty of healthy incident in the book.

Cassell's Family Magazine (London: Cassell and Co., Limited) still maintains its high position in the class of books to which it belongs, and the volume for 1895 may well be described as a handsome volume of healthy reading. The short stories and sketches are well written, and there is an excellent serial, "The Voice of the Charmer," by Mrs. L. T. Meade. There are also some brightly written papers dealing with the work of such popular writers as Sir Walter Besant, the Rev. S. Baring-Gould, the late R. L. Stevenson, Mr. S. R. Crockett, Mrs. Hodgson Burnett, Mrs. Humphry Ward, and Edna Lyall. Chit-chat on dress, together with the articles on artistic work for the home, will be appreciated by the gentle sex, and the monthly record of novelties of invention, science, and discovery will be found an interesting feature of the magazine by the male members of the family. "Boating on the Cam" and "Front Rank Cricketers of To-day" will also appeal to the latter class of readers. Needless to say "The Cabinet and its Secrets," by Sir Wemyss Reid, does not reveal to us any secrets of State, but the sketch is well worth reading nevertheless. Those who look for humour will find it in "Carter's Incandescent Cats," wherein an amateur electrician attempts to use the latent electricity in *felis domesticus* for supplying glow lamps. His experiments lead to some ludicrous consequences.

Katawampus: its Treatment and Cure. By his Honour Judge EDWARD ABBOTT PARRY. London: D. Nutt.—This is a book which will delight not only children but grown-up people as well. The account of the Parliament of Toys is delightful. As in our experience Katawampus is very rife after Christmas dinners, we would counsel uncles and fathers to provide themselves with copies of this book to give away.

DECEMBER JOURNALS AND MAGAZINES.

The *Edinburgh Medical Journal* leads off with Dr. Clouston's very interesting valedictory address to the Edinburgh Medico-Chirurgical Society, Dr. J. A. Macdougall concludes his series of Surgical Cases of Interest, and Dr. W. G. Aitchison Robertson contributes a delightful paper upon Sixteenth Century Therapeutics. The application of a

Digitized by Google

live hen with an incision in the breast is practised still in some parts of the East for snake-bite. There are other papers and articles of interest, and altogether the number is a very good one.

National Review.—The two most important articles are a really admirable paper by the Roman Catholic Bishop of Salford upon the Crisis in Religious Education (the recommendations of the writer at the end of his paper are particularly good), and an account of an Air-car raised by Planes acting like a Kite, by Lieutenant B. Baden Powell.

In the *Humanitarian* Mr. Archibald Little argues that the true cause of China's decay is the practice of bandaging the feet of their women. Miss Rosa M. Bassett has an earnest plea for the better protection of children.

The *Westminster Review* has a good paper, which is really a review of a work by Mr. J. F. Hewitt, entitled "The Ruling Races of Prehistoric Times." The cradle of the human race, it is argued, was in the Southern Hemisphere.

Analytical Records
FROM
THE LANCET LABORATORY.

EXTRACT OF RED MARROW.

(F. B. BENGER AND CO., LIMITED, OTTER WORKS, MANCHESTER.)

THIS preparation is another and useful addition to the remedial extracts of animal origin. It is simply a clear, reddish-yellow glycerine solution of red marrow without objectionable taste or odour. It yields barely any ash on ignition, but sufficient, however, to give a distinct response to the molybdate test for phosphates. The red marrow of bone has, as is known by our readers, been suggested as the chief agent in promoting the development of red blood-corpuscles, and the extract, it might be anticipated, if introduced into the organism whilst in an anæmic condition, might act as a stimulant in the formative process and increase the rate of production of the red blood-corpuscles.[1] That this extract contains these peculiar principles unimpaired is evident from the results of its administration to patients in the Salford Royal Hospital, where in each case there was a marked increase, in some of more than a million red corpuscles per cubic millimetre, in from four to nine weeks. Its use may obviously be extended with probable advantage in other conditions of blood impoverishment. It may conveniently be given spread between thin pieces of bread.

CRADLE BRAND HUMANISED MILK.

(H. AND T. C. EDWARDS, LIMITED, 29, CALEDONIAN-ROAD, KING'S-CROSS.)

It is stated in regard to this preparation that on adding two parts of warm water to one part of milk a fluid is obtained very nearly approximating to the composition of human milk. Carrying this direction out we found the following to be the composition of the diluted milk obtained: total solids, 11·46 per cent.; fat, 3·70 per cent.; non-fats, 7·16 per cent.; mineral matter, 0·60 per cent. This is a very satisfactory result, especially in regard to its richness in cream. The concentrated preparation is successfully preserved without the use of antiseptics and possesses a good creamy taste. With these facts before us we are justified in placing this brand of milk in the list of really valuable and useful foods admirably adapted for infant use.

DISINFECTANT (VITOS) PREPARATIONS.

(FORBES, ABBOTT, AND LENNARD, EAST GREENWICH, S.E.)

These preparations include Vitos liquid dentifrice, Vitos disinfectant (a highly concentrated alkaline fluid), and "phenylated fibre" (which is impregnated to the extent of 25 per cent. with pure tar acid). All three on analytical examination gave unmistakable evidence of the purity of the phenol employed, there being an entire absence of crude tar oils. The "fibre" preparation, the amount of the phenol in which we estimated as 24·90 per cent., which confirms sufficiently the statement that it contains 25 per cent. is a particularly useful and effective one. It offers distinct advantages over mineral powders, is much more absorbent, is flushed as easily as paper through drains, and even when wetted and exhausted can, unlike a finely divided powder, be readily swept up. Vitos fluid disinfectant contains, according to our valuation, at least 85 per cent. of crude tar acid combined with alkali. It is of a port-wine colour and perfectly miscible with water. The dentifrice, which is alkaline, is agreeably scented, and its disinfectant basis is of a purity which is demanded of a preparation intended for the teeth. The phenylated fibre and fluid answer all the requirements of a disinfectant of real value. They are satisfactory because they contain a maximum quantity of the active disinfectant agent employed and because the agent itself, as we have shown, is pure. For the various useful purposes to which they may be put these preparations, therefore, may be trusted. Dr. Klein has reported excellent results in a series of severe bacteriological tests.

TROMMER—(1) MALT EXTRACT, (2) WITH COD-LIVER OIL, (3) WITH CASCARA SAGRADA.

(AGENTS: F. NEWBERY AND SONS, 1 AND 3, KING EDWARD-ST., NEWGATE-STREET, E.C.)

These preparations bear the name of the author of "Trommer's Test for Sugar," whose researches on food and nutrition are now well known. The plain malt extract possesses a fine barley flavour and manifests a high degree of diastasic activity, as shown in our experiments by its rapid digestive effect upon starch emulsion. The same digestive property is possessed, but in a modified degree—owing, doubtless, to the presence of oil—by the cod-liver oil and malt preparation, which contains 60 per cent. of Trommer extract of malt and 40 per cent. of fine Norwegian cod-liver oil. It presents the appearance of a perfectly uniform emulsion under the microscope. Lastly, the preparation of malt extract with cascara sagrada offers obvious advantages. It is a powerful digestive of farinaceous substances and, in addition, acts as a tonic and mild laxative. Each preparation bears evidence of careful manufacture and of the selection of ingredients of good quality.

New Inventions.

"THE LEICESTER" PERFECT PLASTER OF PARIS BANDAGES.

ON the original introduction of plaster of Paris bandages, now a good many years ago, the extemporaneous preparation of these most useful articles with the ordinary plaster used by figure-makers was a decidedly troublesome and unclean process. Even in hospitals this was recognised, while in private practice the necessity for providing a stock of efficient plaster, and for securing the aid of competent assistants during the application of the bandage or splint, constituted a serious drawback. These difficulties have, however, been completely solved by Messrs. A. de St. Dalmas and Co., Leicester, who introduced some time ago a bandage in which the plaster of Paris in very fine dry powder is thoroughly incorporated with the woven fabric. They claim for this material the special advantage that it is not affected by age or exposure, and a recent trial made with samples delivered by them more than eleven months previously has shown that a very satisfactory splint may be made with ten spirally-wound layers of the "medium" bandage, separated by one thickness of straight [illegible]. The stock sizes are either five yards [illegible] a half wide (two qualities) for rolled bandages, or one yard long and eight inches wide for cutting [illegible]

THE LANCET.

LONDON: SATURDAY, DECEMBER 7, 1895.

THE medical profession will have learned with the deepest pleasure of the election of Sir JOSEPH LISTER to the position of President of the Royal Society. Several physicians have occupied this presidential chair, but only one surgeon has hitherto had the honour—which we may venture to call the supreme honour that can fall to the lot of the scientific man—conferred upon him. We exclude Professor HUXLEY in this connexion, and find that Sir JOSEPH LISTER'S single companion is Sir BENJAMIN COLLINS BRODIE, who was elected a Fellow of the Royal Society in 1810, at the early age of twenty-seven, and was Copley medalist in 1811, and became President nearly fifty years later. Sir JOSEPH LISTER, living in a more competitive age, when scientific knowledge is not so rare or so difficult of acquisition, did not obtain the coveted Fellowship so early in his career; but although his name is and will ever be connected with antiseptic surgery, and all that is meant by that term, it must not be forgotten that he won his spurs many years earlier in general, anatomical, and physiological work. It is now fifteen years since Sir JOSEPH LISTER was a medalist of the Royal Society, and as he has been foreign secretary for a considerable period it was all in the nature of things that the highest office should fall to him, unless by any chance the profession of surgery should have been deemed by his scientific brethren too limited or, rather, too specialised a pursuit to fit a man for the post.

On this point we wish to dwell. It is exceedingly gratifying to the medical profession that a surgeon of Sir JOSEPH LISTER'S particular quality should have been chosen to occupy the position of President of the Royal Society, for he is the pioneer of his science in our country, and the leader in a world-wide movement about which it is so trite a thing, but so true a thing, to say that it revolutionised modern surgery. It is a matter of common notoriety that no surgeon has so affected the whole practice of surgery of his day as Sir JOSEPH LISTER has affected our present practice by his teachings in reference to asepticity, and his position as the titular head of the science of the nation is a compliment to the surgery of the nation of the highest and most unmistakable sort. It is a proof that the Royal Society does not look upon the pursuit of surgery, as so many worthy people do, as a sort of upper grade of cabinet-making, but recognises that in its proper developments it is a science, not a craft, and that whoever would be a leader in surgery must have more than manual skill and exact anatomical knowledge, must have also a large scientific range over which his mind can roam at will. The antiseptic system of surgery was not a happy thought proved by an experiment or two and developed in a few telling papers, backed by a few successful cases. No; it required for its discovery and proof an amount of faithful, hopeful, and charitable work which it is impossible to estimate—faithful, for every step forward upset some time-honoured prop of surgery; hopeful, for the end must have seemed far and the dissemination of the doctrine slow; and charitable, for many were found in opposition to the innovation whose antagonism had to be recognised as honest and intelligent, and could not be classed contemptuously as ignorant. Therefore it is that the profession, with a laudable and solid selfishness, will rejoice in the call of Sir JOSEPH LISTER to the seat of NEWTON, DAVY, and HUXLEY. It is not the skilled workman that is being honoured by the Royal Society—though had they desired to be presided over by such their choice need not have fallen in another place than it has—but the science of surgery in its most modern development and in its broadest meaning, a surgery to which physiology, chemistry, botany, and physics have contributed of their best.

There can be no doubt whatever, as the late President of the Board of Trade said at the annual dinner of the Royal Society, held last Saturday evening, that in the early days of the society it was very closely connected with medicine and surgery, while of late years elections from the roll of our profession have been less frequent. This is true. We have many Fellows of the Royal Society in our body, but not the proportion of ancient times. The falling off has been inevitable and due to that great physiological process, the process of specialisation of function. In days gone by the physicists, botanists, entomologists, and many of the archæologists and antiquarians who were elected to the Royal Society were medical men, for the scientific training necessary even at that day to obtain the knowledge upon which to practise medicine stimulated in the physician and surgeon a desire for learning. When the medical profession had almost a monopoly of the scientific knowledge of the land they had, and very rightly, a great claim upon the Royal Society, and were elected Fellows in large numbers. This is now, of course, all altered, and the physicists and botanists stand by themselves as the surgeon stands by himself. Each draws on the knowledge of the other, but the more pure the pursuit the more divergent the path. All that is hoped is that representative men of each science, without impartiality, may find their way into the Society and reach its highest office. And of the impartiality we may feel assured, for now, at any rate, the virtue reigns supreme in Burlington House. And this is why there is not a savant in the world, from old France to new Japan, from northern Norway to southern Australia, who does not consider that to have been elected a Fellow of this body is an honour, in that it hall-marks his work, stamping it with a stamp that is never placed upon any metal save such as appears genuine to all possible human assaying. There is no body more free from all taint of nepotism, all suspicion of favouritism, all desire to suit its elections to the purse or personal prestige of the candidate. There are dukes and princes in the Royal Society, and there are men who have risen from the ranks, but impartiality has dictated their elections. They have advanced the cause of learning. To preside over such a body the acknowledged leader of modern surgery has been called,

Digitized by Google

and in congratulating Sir JOSEPH LISTER upon the fact we congratulate the whole of the profession.

WE feel that in the case of Dr. WIGHT there are some points of interest on which it will not be out of place to say a few additional words. In another column will be found a letter dealing with the more especially obstetric aspect of the case, in which the possibility that the injury found on post-mortem examination might have happened spontaneously, is suggested. That this might have been so was, it will be remembered, admitted by Dr. GRIFFITH in his evidence at the inquest, reported in THE LANCET of Sept. 28th last. At the same time he expressed his opinion that the laceration had not occurred spontaneously in the case in question. It appears by the evidence of MARY ANNE HAWKEN, the nurse, that after trying to deliver with the forceps for some time Dr. WIGHT attempted to turn the child. When he failed to deliver by version "he again applied the instruments." The nurse went on to say "they did not lodge on that occasion," the inference being that on the previous occasion the forceps had appeared "to lodge" in the usual way. Supposing that the tear through the posterior vaginal wall into Douglas's pouch did not occur spontaneously, although this is admitted to have been possible, it seems, in view of the fact that turning was attempted, quite probable that the laceration may have occurred when Dr. WIGHT endeavoured to perform version. It is well known that in some cases rupture of the uterus or vagina, or of both, may occur without any blame necessarily attaching to the operator. To our thinking, it is a much more probable thing that the rupture of the parts in the present instance may have occurred either spontaneously, or during the attempt at version, rather than by a blade of the forceps being thrust through the posterior vaginal wall into Douglas's pouch. We should say that it would not be an easy thing to do this even intentionally, using any ordinary degree of force. And in connexion with this point, granting for the sake of argument that Dr. WIGHT's state of mind was such as to render him rightly responsible for his actions, it should be remembered that he is a general practitioner with thirty years' experience, during which time he has attended some 5000 cases of labour. It is only fair to suppose that he must, therefore, have had a great deal of practical experience in the use of the forceps, and it is assuming a good deal to take it for granted that he used so much force in introducing one of the blades as to push it through the posterior vaginal wall into the peritoneal cavity. On the facts it is, as we have said, more probable that the laceration that occurred took place when version was being attempted, and when the parts, already greatly stretched, were still further stretched by the introduction of the hand. It is a mistake to suppose that the rent must have been caused by great violence on the part of Dr. WIGHT. If a powerful uterine contraction occurred after the hand was introduced, the parts being already greatly stretched, the laceration might have occurred though the hand was kept quite passive. The fact that, according to the nurse's evidence, the forceps "did not lodge" after the attempt at version would seem [illegible] corroborate this view, as probably the laceration had [illegible] occurred, and one blade on this occasion had passed [illegible] the peritoneal cavity. In this respect there is some [illegible] between this case and some cases of so-called perforation [illegible] the uterus by the curette. AUVARD has clearly establish[ed] that in some such cases, when the operator has thought [illegible] perforation to be caused by the curette, it is not really [illegible] but that the perforation had been really caused by [illegible] preliminary measures used to rapidly dilate the cervix—[illegible] the curette then merely discovers the rent so produced. [illegible] the present case it would seem similarly very probable that [illegible] laceration occurred during the attempted version, and [illegible] the forceps then merely discovered the rent so made. [illegible] are not in the least degree desirous of finding excuses [illegible] Dr. WIGHT, but we feel it right to say, quite apart [illegible] any question of his state of mind, that on the facts [illegible] reported at the inquest, and simply as a matter of scientific [illegible] opinion, the lamentable accident that occurred may [illegible] been, as our correspondent "M.D." suggests, in the category [illegible] of those unavoidable accidents that will occur from time [illegible] time, and for which at all events medical men should [illegible] be held criminally responsible.

So much for this aspect of the matter. If, as [illegible] HANNAH said, there are sufficient grounds for [illegible] that Dr. WIGHT was not in his right mind at the [illegible] this would, of course, *ipso facto* absolve him [illegible] being held criminally responsible for what occurred. [illegible] the result of the inquiry which we suppose the [illegible] Secretary will order into this question will be [illegible] with interest. Moreover, if there were at the time of [illegible] accident indications clearly perceptible to those around [illegible] that Dr. WIGHT was not, for whatever reason, in a [illegible] state to undertake the attendance upon the case, [illegible] think those who observed these indications took upon [illegible] themselves a great responsibility in standing by and [illegible] allowing him to do what he did, especially when it was [illegible] clear that an operation was needed to effect delivery. [illegible] The patient's husband and the nurse both swore that they [illegible] noticed Dr. WIGHT to be in a dazed and stupid condition, [illegible] and the sister of the deceased gave similar evidence. [illegible] We are certainly surprised that the husband did not [illegible] interfere if he noticed something peculiar about Dr. [illegible] WIGHT'S mental state. There is no doubt whatever [illegible] that Dr. WIGHT had been ill for several months [illegible] the after-effects of influenza, and that he suffered from [illegible] sleeplessness and loss of appetite, also that he had taken [illegible] a full dose of chloral on the day on which the accident [illegible] happened. The case seems to us, in this respect, to afford [illegible] a lesson to those who are unwilling to recognise that failure [illegible] of health is an indication to stop work. There is no doubt [illegible] that a man in Dr. WIGHT'S state of health should give up [illegible] practice for a time, and seek to recuperate his powers by rest [illegible] and other treatment. Persistent sleeplessness more particularly [illegible] larly may be taken as indicating the need for complete [illegible] abstention from all mental effort. The use of chloral or [illegible] similar hypnotics by medical men is especially to be [illegible] deprecated, since they can always obtain such drugs on [illegible] their own advice alone, and because they may be tempted [illegible] too readily to resort to what is generally ready to hand [illegible] hand in the house. Dr. WIGHT would have been well [illegible]

Digitized by Google

advised if in the first instance, when his health began to fail after his attack of influenza, he had taken a holiday such as would have been afforded by a long sea voyage. The probability is that in such a way he might have soon begun to recover his mental and bodily strength, and that the power of obtaining natural sleep—"the innocent sleep," and not that hurtful variety obtained by the use of chloral—would have soon returned. Had this been the course adopted we should not have had any observations on his dazed and stupid condition when attending Mrs. FLETCHER.

It cannot be too clearly impressed on every practitioner that if he attends a serious case when, for any reason, he is more or less, through illness or otherwise, unfit for active duty, his unfitness will be no excuse in the event of anything going wrong, and there is the possibility that he may be held responsible for what might have been an unavoidable occurrence, even if he had been mentally and physically at his best. We do not say that this has been so in the present instance, but it would be unfair not to admit the possibility that such might have been the case.

ON Thursday, Nov. 28th, at 12 noon, his Grace the Duke of DEVONSHIRE received a deputation of delegates from the various bodies interested in the establishing of a Teaching University for London. The deputation, introduced by Lord KELVIN, consisted of delegates from University, King's, and Bedford Colleges, the medical schools, the Royal Colleges of Physicians of London and Surgeons of England and the Society of Apothecaries, the theological colleges, the University of London, and some other bodies interested in the higher education of London. The following resolution was the important one that the deputation brought before the notice of the Lord President of the Privy Council, and many speeches, urging its necessity from various standpoints, were made by members of the deputation:

"That the Government be requested to introduce, at an early date, a Bill, similar to Lord Playfair's London University Commission Bill, 1895, appointing a Statutory Commission to carry out the recommendations of Lord Cowper's Commission, but with an added clause giving [in accordance with precedent Acts of similar tenor] to all institutions or persons directly affected by any statute or ordinance proposed by the Statutory Commission, a right of appeal to the Privy Council for the disallowance or alteration thereof, previous to such ordinance being laid before Parliament for confirmation."

The Duke of DEVONSHIRE showed but little sympathy towards the object of the deputation, for he immediately began to administer not merely the traditional cold douche, but even to put the recommendations of Lord COWPER'S Commission into a freezing mixture. He pointed out that there was a large number of candidates, non-collegiate students, who might be injuriously affected by the appointment of a Statutory Commission on the lines of Lord COWPER'S Commission. But surely this is a question of safeguards which a Statutory Commission is the proper body to settle. We believe it to be a difficult but by no means an insoluble problem to place collegiate and non-collegiate students on similar platforms for obtaining degrees. But his Grace next came to a more puzzling question—viz., the veto of Convocation on the granting of a new Charter. The deputation wished to urge that the two last votes in Convocation had decided its agreement to a new Charter, but he maintained, and quite rightly, that Convocation, unless its statutory right was taken away, had the power to approve of or veto any scheme proposed by the Statutory Commission. If the Lord President went further and was inclined to allow proxy voting, as in the case of the election of a member of Parliament, then he with Sir JOHN LUBBOCK is wrong and is departing from the regulations of the University. Voting for or against a new Charter, as for the admission of women to degrees, has always been a personal vote, and no proxies have been admitted. A further statement will be laid before the Duke of DEVONSHIRE to show that the rights of the existing graduates of the University of London and the just privileges of "external" students will not be interfered with; but we question whether this will materially alter his Grace's attitude with regard to the question. At present it seems to us that the movement has arrived at an *impasse*, but it must not be allowed to rest where it is. A university, capable of granting degrees to London students on similar terms to those on which they are conferred on Scotch and provincial students, must be established in London in the interests of general education and especially of the large number of medical students in the metropolis.

Annotations.

"Ne quid nimis."

PRESENTATION TO SIR HENRY ACLAND.

A REPRESENTATIVE company, including the Warden of All Souls, the Rector of Exeter, the Warden of Keble, the Provost of Queen's, the Principal of Hertford, Sir Joseph Lister (the new President of the Royal Society), and Professors Max Müller and Dicey assembled in the hall of All Souls' College on Wednesday last to present to Sir Henry Acland an address and an accompanying testimonial. The testimonial took the form of a bust, which will be placed in the museum of the University, and a cheque for a large sum of money, over £3000, which will be employed in carrying on the work of the Sarah Acland Home for Nurses. The address justified the testimonial, stating that it had been subscribed for in commemoration of the long and faithful service that Sir Henry Acland had rendered to the University, city, and county of Oxford, and the part which he had borne in the advancement of medical science in England, more particularly in the direction of sanitary reform and preventive medicine, during the forty years of his occupation of the chair in the University of Regius Professor of Medicine. The Provost of Queen's (Vice-Chancellor of the University) in making the presentation took these words as his text and spoke in eloquent expatiation of them, and all the profession will feel that it would not be easy to exaggerate the terms that could be employed about Sir Henry Acland in the above connexions. As scientific physician, practical sanitarian, faithful administrator, and kindly man he stands so high in the estimation of us all that no eulogy would seem extravagant.

Digitized by Google

OBLIGATIONS AND POWERS OF SANITARY AUTHORITIES UNDER THE FACTORY AND WORKSHOPS ACTS.

THE sanitary provisions contained in the Factory and Workshops Acts of 1878, 1883, 1891, and 1895, together with the provisions relating thereto contained in the Public Health Act, 1875, and the Public Health Acts Amendment Act, 1890, form an intricate mass of legal enactments which it is hardly to be expected the members of sanitary authorities will themselves take the trouble to master in detail. The obligations and powers of the sanitary authority under the above Acts are, however, so numerous and of such vast importance to the health of the working classes of this country that it is incumbent upon all those having to do with their administration to possess at least a general idea of the provisions of the Acts in question; and it is also desirable that there should be a clear understanding in the several departments of the sanitary authority as to what provisions shall primarily concern each department. In connexion with these aspects of the question we have just received a very concise summary of what may be regarded as the direct or indirect sanitary provisions of the Factory and Workshops Acts and the Acts allied to them, which has been compiled by the medical officer of health and the engineer of Bristol for the use and information of the sanitary committee of the town council. This summary should be of the greatest value to the members of the sanitary committee, and it has, too, an interest as evidence of the enormous range of knowledge which the medical officer of health of the present day is expected to possess. Not only must he have had a scientific and medical education of no mean order, an education which should comprise a knowledge of geology, bacteriology, and kindred subjects, but it is also a distinct advantage to him, if indeed it is not expected of him, to be able to arrange for the instruction of the sanitary authority an accurate summary of intricate legal enactments. We are afraid however, that in their turn the sanitary authorities do not always recognise that in matters appertaining to public health the labourer is worthy of his hire. The Acts relating to factories and workshops are becoming numerous and involved, and it appears to us that we are reaching a state of affairs not unlike that which obtained prior to 1878, and which led to the passing of the Factory and Workshops Act of that year, an Act that is often spoken of by the appropriate name of the Factory Consolidation Act.

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

MR. SHARP, in a letter which appeared in the *Times* of Friday, Nov. 29th, says: "This will be my last word upon the question." Very likely; Mr. Sharp is evidently realising the truth of that admirable saying, "Qui s'excuse s'accuse." Let us put down plainly what has happened. 1. The Board, on the motion of Mr. Sharp, appoint medical men to examine cases in which the medical certificate produced is considered by the divisional superintendent to be doubtful.[1] 2. Mr. Sharp says: "The majority of the cases which have been submitted to these gentlemen have been cases in which no medical certificate has been produced."[2] 3. "The great body of medical men approve of the action of the Board with regard to medical certificates."[3] 4. Letter from Dr. Glover, one of the direct representatives of the profession on the General Medical Council, repudiating this.[4] 5. Mr. Sharp replies.[5] 6. More letters from medical men pointing out that "the action of the Board is unjust and disrespectful."[6] 7. Mr. Sharp says his last word, again pointing out that most of the cases examined by the [illegible] appointed medical men are those in which there [illegible] no medical certificate obtainable.[7] 8. On the Tuesday before the last word Mr. Athelstan Riley rose for precedence to bring in a motion to refer the whole matter to the medical officer of the [illegible] Board. Mr. Sharp, curiously enough, considering that "the great body of medical men approve" &c., opposed this motion. Well, he has ignored the Board's medical officer all along, so, perhaps, it was only natural. We remind Mr. Sharp that so long as the resolution of May 30th stands he will find it increasingly difficult to get medical certificates. 9. Another letter from Dr. Glover pointing out the profound dissatisfaction of the profession.[8] We want a plain answer from Mr. Sharp to the following questions. 1. Has he, or has he not, appointed through his Board a set of medical men to sit in judgment upon the decisions of other medical men? 2. If the use of the Board-appointed medical men is only to examine when no certificate can be got, why not accept the amendment about qualified practitioners men moved at the Board meeting of June 27th? 3. If the profession is with him, why does not he ask the opinion of the medical officer of the Board?

"BACTERIA IN THE DAIRY."

THAT we may count upon microbes sometimes as our friends and sometimes as our enemies is well illustrated in the bacteriology of milk and milk products. Though milk may leave the udder perfectly sterile, yet a few moments' contact with the air, and especially the air of insanitary surroundings, are sufficiently long to be the starting-point of the development of a whole microbial menagerie. By fission alone—that is, by splitting in two, and by the resulting two dividing again in the same way—one bacterium may become the parent of over sixteen million bacteria in twenty-four hours. The composition of milk is such as to be most favourable to the growth and development of organisms, pathogenic and non-pathogenic. Some are detrimental to the healthy condition of the milk itself, or, in other words, milk has its own diseases to contend with. Experience is ever teaching how imperative it is that the strictest care should be taken to protect milk against the possibility of microbial invasion. The risks of pollution are great, and may arise from an unhealthy or dirty condition of the cow, or of the stall, or of the milker's hands and clothes. The air of the cow-house is frequently made insanitary by cleaning it out and dislodging dirt just previously to milking, and another source of contamination is the diluting of the milk with unwholesome water which may be infected with typhoid fever or cholera poison, or by placing the milk in dirty vessels, or by exposing it to the atmosphere of warm and unhealthy places, as cupboards. With these possibilities of pollution in mind the advantages gained by sterilising or Pasteurising milk by boiling are evident. Particularly is this so in the case of bottle-fed infants, the lives of many of whom would be saved from fatal diarrhœa, so frequent in artificial rearing, were these precautions taken. The same lesson is taught by the fact that mother's milk is sterile. Although boiling will destroy the disease-producing germs in milk, it may still leave spore-bearing bacteria, which in course of time would produce undesirable changes in the milk itself and render it unwholesome. On the other hand, there are friendly germs to be found in milk whose functions can be cultivated and turned to account in the production of an acceptable flavour in cream and in butter. After clearing the milk or the cream of competing organisms by Pasteurism it is sown with

a pure culture of lactic acid producing organisms. The flavour of the butter and, moreover, its keeping qualities being dependent upon the character of the souring process undergone by the cream preparatory to churning, a uniform product acceptable in both these respects may be obtained by proceeding carefully on these lines. The inculcation of these methods amongst dairy farmers would add an impetus to the milk products industry, and probably bring it into a greater state of prosperity. It is satisfactory to record that efforts are already being made to do this by lectures and the publication of lectures in pamphlet form and in the agricultural papers.[1]

SLUMS IN CARDIFF.

AT the meeting of the Cardiff town council held last week a member stated that some of the houses in the poorer districts reflected great discredit upon their health department, and that in one house people were found lying without any covering upon a mattress swarming with vermin. If that were true, he added, their by-laws were either insufficient or not enforced, and the people of Cardiff were stirred by the pictures which had been drawn of life in these localities. He proposed that a sub-committee should be appointed to visit these poor districts, with their medical officer of health, and report to the council, which proposal was carried.

INFANTRY SWORD EXERCISE AND THE RECENT HANDBOOK FROM THE WAR OFFICE.

WE do not often meddle in matters *ultra crepidam*. There occur, however, now and again, special occasions when an expression of our opinion on subjects apparently outside the medical frontier is imperatively called for. Such an occasion is the present. Two letters have appeared in our columns respecting the new infantry sword exercise, and we claim the right and assert our competence to deal with the question in its medical aspect. In the first of these communications—that from Dr. Chepmell and Dr. Savage—attention was drawn to the hitherto unnoticed defects of the new Masiello system; the objections were stated tersely (and in our opinion correctly) by these gentlemen, the letter was copied by journals all over the kingdom and gave rise to much comment and correspondence, chiefly in the military press. The second critique—that in our issue of last week—is from the pen of no less an authority than Mr. Clinton Dent, an expert not only in anatomy but also in swordsmanship. This last is an exhaustive analysis of the new method, and lays bare one by one the grave defects which lie at its root. We entirely agree in the conclusions drawn by our medical critics as to the objections to this system, and would refer our readers more particularly to three of the weakest points: (1) the "on guard" position, of which the wide separation of the feet, the forced extension of the arm, and full pronation of the hand must speedily induce fatigue; (2) the exaggeration of the lunge and consequent loss of balance; and (3) the projection of the centre of gravity and difficulty of recovery. Some military men there are nowadays who maintain that as a weapon the sword, if not entirely useless, is at all events very inferior to the revolver. This may be so, but it is quite possible that in war time circumstances might arise to render the revolver unavailable, and the soldier might have the sword alone to depend upon. The same theorists declare that it is impossible ever to make a good swordsman of the British soldier, and yet these allow that the same man is as good as, if not better than, most foreigners in games such as cricket and football and general athletics. Now we venture to predict that if the same amount of time and encouragement as is given to these games was accorded to practice with foil and sabre, this stigma of incompetence, if merited at all, would speedily be effaced, and we should take our proper place as swordsmen in the front rank of nations. The question of swordplay we hold to be one of national importance, and a neglect on our part to comment on the materials before us would almost involve a lack of patriotic feeling. We trust that our military authorities may be induced to look a little more closely into the principles contained in the new manual and prevent our fighting executive from making a false start in this important educational course.

[1] We have recently received a copy of an excellent lecture of this type entitled "Bacteria in the Dairy," delivered before the Irish Dairy Association by Dr. E. J. McWeeney, the copyright of which has been secured by the proprietors of the Farmers' Gazette for the Belgravia Dairy Company.

THE UTILITY OF FIRST AID.

AT a meeting of the South-Eastern Railway Ambulance Class held recently attention was drawn by Sir Myles Fenton to the public usefulness of these classes. Among the employés of the South-Eastern Railway Company there are 305 servants qualified to render first aid, and no less than seventy cases are reported where useful practical work has been done. Among them the general manager of the company referred particularly to the case of a fireman, Alfred Newman, whose presence of mind and knowledge of first aid had been the means of saving the life of an engine-cleaner, the victim of a practical joke. The cleaner had entered the smoke-box of an engine when his colleagues, by way of what they called a joke, shut the door of the box and covered it over with sacking. The fireman, who soon after passed, seeing the lads watching the door and laughing, inquired as to the cause, and on learning it forced open the door and dragged the cleaner out in an asphyxiated condition. He was, however, eventually resuscitated by Fireman Newman. A case was also mentioned in which another fireman named Ockenden gallantly saved the life of a man from drowning. The first case is worthy of note by reason of the fact that the man who saved the life of the cleaner had not at the time taken his first certificate, and the illustration it affords of the practical utility of even a little knowledge in such cases. Great praise is due to the man's presence of mind and the prompt application of his knowledge.

"TUBERCULOUS" *vel* "TUBERCULAR"?

FOR some years past we have, so far as we are able to control the terminology employed in these pages, been particularly mindful of the different senses attaching to the word "tubercle." Originally a purely anatomical and coarsely morphological expression, it has come to signify a special infective disease the ultimate cause of which is admittedly a specific microbe. The anatomical term of course remains, it is etymologically accurate, but the confusion that has arisen from its transference from this, its legitimate and general application, to denote a special kind of nodule evoked by a specific agent is rendered worse confounded when the phrase is used in the attributive sense. Although custom has hallowed and made inviolate the noun "tubercle" in its particular as well as in its general application there is no need for a similar commingling of terms when we employ its derivative adjective. The word "tubercular" is the anatomical equivalent of tubercle and has always been so employed in anatomical text-books. It has also, with a perversity that perpetuates the initial blunder, been equally applied to denote the various pathological changes induced by the presence of the bacillus tuberculosis. Our readers will perceive that the distinguished surgeon who has just delivered the Bradshaw Lecture has adopted this same phraseology. In this respect he is by no means singular, for the like use of the term is made by many other writers and teachers of medicine and surgery. On

Digitized by Google

the other hand, not a few—and amongst them may be reckoned THE LANCET—have attempted to dispense with "tubercular" as indicative of the specific infection, preferring to it the term "tuberculous," which, it may be remarked, is also commonly employed in the pathological writings of our French and German neighbours. We would fain see this latter practice universally adopted, not from any sense of pedantry, but as a matter of lucidity and accuracy in description. As for those who employ both terms indiscriminately in describing the same things, we fear that they are past praying for. Scientific nomenclature is certainly not free from etymological blemishes, but, at least, when there is a choice of terms let us be consistent in the way in which we apply them.

THE WIDOWS OF MEDICAL MEN.

WE have received the following pathetic and, truth to say, somewhat illogical letter, in which the writer confuses the Holloway College for Women with the Hospital for the Insane at St. Ann's Heath, but which we have decided to print because it may do good. The fortunes of many poverty-stricken widows of members of our profession are not likely to be ameliorated by the publication of the letter; but if work that she can do properly should find its way to but one woman through its means we shall be glad that we gave it space in our columns:—

To the Editors of THE LANCET.

SIRS,—Will you grant us a small space in THE LANCET? I have been asked by a great number of my sisters in sorrow to bring their case before the public with the hope that it may meet the eyes of the trustees of Holloway's College, Virginia Water. For sure am I that such a philanthropic old man as Holloway was never intended his money to be spent on a large institution that would rob the widow and fatherless of the medical profession. Let me explain. The doctor—the bread-winner—is often taken off in early life before he has had time to make a provision for his children. Hard work or devotion to his work in holding out a helping hand to others in his profession cuts his life all too short for all he meant to do; and the poor wife must hear the sad words at last—keep the home together if you can for the sake of the little ones! Will your readers tell me how, brought up in a gentle home herself. Where is the Englishman that would make the struggle with the world more hard and bitter than it is for her? And yet how many do this for want of a little unselfish thought, and send their patients to a public institution, knowing all the time that the only means open to a doctor's widow is to take into her home such patients to nurse and care for as she may feel qualified to undertake, and this means bread for her children and self, hard and honestly earned. Yet this Holloway's College is now not only open to take in certified cases of insanity, but also those who are suffering from minor mental diseases may place themselves there, so robbing the widow of the only chance of a livelihood. Has the cry of the widow no place in England? We ask not for charity; we would scorn it as gentlewomen. But we do ask you to be pitiful and courteous, and forget not your colleague's less favoured little ones and take not from us the children's bread we would gladly earn by sending your patients to public institutions, and let those who read my letter with contempt remember the eye of the great Master is over all.—I am, Sirs, yours faithfully,

G. B. R.

It does no cause good to be irrationally sentimental about it. We are personally concerned with the widows of medical men, but it must be admitted that the clergyman and the solicitor are every whit as much family bread-winners as the members of our profession, and that the early death of either is apt to leave the widow and children in a position as sad as that portrayed by our correspondent. But if any of our readers have work of the kind vaguely indicated in the foregoing letter at their disposal, we would suggest that, if they think the duties can be quite fitly undertaken by the widow of a medical man, they should give her a trial. The course would be in conformity with the best spirit of our profession, and be an expression of *esprit de corps*.

THE DENTAL HOSPITAL OF LONDON.

THE annual dinner of the staff and past and present students of this hospital took place on the 30th ult. at the Café Royal, under the presidency of Mr. Frederick Canton. Although, as might be expected, the occasion was one on which the needs of the hospital in regard to its extension in the shape of a new building were urged, still an equal share of the speaking was devoted to the necessity of united action on the part of dental surgeons to raise and establish their profession on a level of dignity comparable with that of the medical profession. It is doubtless largely this spirit animating the staff and students of the Dental Hospital of London which leads to—what must have been apparent to a visitor—such an excellent unanimity of feeling between them and to an *esprit de corps* which must prove also a powerful aid to the furtherance of the scheme for the projected new hospital. Striking and gratifying evidence of the practical interest in this movement—which it should be remembered, has important educational as well as philanthropic ends in view—is afforded in the list of the large amount of money contributed by the members of the staff and the students themselves. Dr. John Walker, the treasurer of the hospital, announced that subject to raising £3000 in order to settle the interest on loans, they were within measurable distance of laying the foundation stone, an announcement which was, of course, received with vigorous applause. He attributed this satisfactory position to the activity and zeal of the dean and the energetic secretary. They still appealed for funds to go on with the work. Dr. Sidney Coupland, in proposing the toast of "Hospital and School," expressed sympathy with the scheme, and trusted it would not be long before the new building would be completed, that would be worthy of an institution which in the past, in spite of its limited accommodation, had afforded relief in a distressing manner to thousands of the poor and had provided an efficient course of training for dental students. There was a very representative company present, which included most of the deans of the London medical schools.

TREATMENT OF ADDISON'S DISEASE.

THE treatment of Addison's disease by causing the patient to eat the adrenal bodies of a sheep has been suggested by more than one observer, and some successful cases have been reported. Another case is published by Dr. C. G. Stockton in the *Medical News* of Philadelphia for Nov. 16th. The case was that of a married woman aged forty. It was said that her mother suffered from some affection resembling that for which the daughter now sought relief. The history of her illness was that for three years she had complained of the symptoms of Addison's disease—weakness, vomiting, loss of flesh, great muscular debility and intense bronzing of the skin, which over the regions naturally pigmented presented the colour of dark mahogany. There was also unnatural pigmentation of the mucous membrane of the lips, cheeks, and pharynx. The gastric contents on examination showed an absence of odour and mucus; the acidity was very faint; hydrochloric acid was absent and lactic acid appeared as a mere trace. There was some diarrhœa. Both kidneys were movable. Above the left kidney, closely connected with it, moving with the kidney yet movable while the kidney was held still, was an irregularly shaped body, about the size of a hen's egg, which was slightly tender upon pressure. It was presumed to be a diseased adrenal. The pulse was somewhat slow and feeble, and at times very infrequent. Examination of the blood showed 1,800,000 red corpuscles to the cubic millimetre. The hæmoglobin was 30 per cent. There was marked leucocytosis, and also poikilocytosis. The patient had for some months been taking iron and arsenic. These remedies were continued, and in addition she was advised to inhale five gallons of oxygen gas three times daily and to eat daily two uncooked adrenals from a sheep. The treatment was commenced on June 23rd, and on July 6th the patient returned and showed great improvement in colour and general appearance. Her appetite had returned with her appetite. She was hungry for the first

Digitized by Google

time in five years, she said. There was a diminution of the pigmentation, as well as a decided increase in strength; the red blood cells had risen to 3,000,000 to the cubic millimetre; the abnormal forms had much decreased in number. The improvement steadily progressed, and on Sept. 14th there were 4,000,000 red blood cells to the cubic millimetre and 80 per cent. of hæmoglobin. On Sept. 27th the contents of the stomach were again examined, but no change for the better could be discovered in her digestion although she had gained six pounds in weight. The pigmentation had almost disappeared from the hands, face, and breasts. The areolæ of the nipples were no darker than is common with women who have borne children. The most striking improvement was seen in the pulse, which was large, strong, and frequent. The blood pressure was considerably above that of health, but it did not show that high tension mentioned by Professor Schäfer and Dr. Oliver. The glands were prepared as a sandwich, and three were occasionally taken without causing discomfort to the patient. On Oct. 1st she was in better health than she had been for five years, and all medication had been withdrawn, save hydrochloric acid and pepsin. Dr. Stockton remarks that an adrenal that is palpable in a woman forty years of age is very suggestive of malignancy; but the results of the examinations of the blood afford the hope that the adrenal disease is not carcinomatous in nature.

THE RESPONSIBILITY OF "PECULIAR PEOPLE."

STRANGE as are the views on medical treatment maintained by the sect of "Peculiar People," they are not more astonishing than is the laxity with which legal processes have been employed in regulating their application. It matters little apparently that the efficacy of recognised methods of treatment has been abundantly proved and universally admitted. A few persons, misled by their own too literal and irrational reading of a Scripture text, refuse to be convinced. The hazard they thus invite, moreover, is not theirs only. The responsibility they assume is not for themselves alone. Those dependent upon them suffer also and have no option. The parent prays, anoints, and does no more; the child dies. This proceeding, it appears, constitutes merely an error of judgment, a well-meant omission, fatal indeed, but requiring no severer punishment than a reprimand. The question of prevention is here strangely overlooked. Not long since four children in one family thus died at Southend, studiously, religiously, neglected by their peculiar parents. A jury at the November assizes listened to the story of their sufferings and their mismanagement and refused to convict, considering, no doubt, that the evident sincerity of motive should constitute an excuse. If their decision be compatible with our present rendering of law on this subject we have clearly need of a new definition of neglect such as will limit parental responsibility, however well-meaning, as regards this important matter, and even allow its transference, if needful, to parochial or other competent authorities.

THE ROYAL SOCIETY.

THE anniversary meeting of the Royal Society was held at Burlington House on Saturday last, St. Andrew's Day. Lord Kelvin, who delivered the presidential address, referring to the losses which the society had received during the past year by the hand of death, paid a well-deserved tribute to the memories of Huxley and Pasteur. In his financial review of the society the President said that in answer to an application to the Treasury £1000 a year had been granted for the purpose of aiding in the adequate publication of scientific matter. After the address the medals were presented as follows:—The Copley Medal to Professor Karl Weierstrass for his investigations in pure mathematics: a Royal Medal to Professor James Alfred Ewing, F.R.S., for his investigations on magnetic induction in iron and other metals; a Royal Medal to Dr. John Murray for his services to biological science and oceanography in connexion with the *Challenger* reports and for his original contributions to the same; and the Davy Medal to Professor William Ramsay, F.R.S., for his share in the discovery of argon and for his discoveries regarding gaseous constituents of terrestrial minerals. The officers and Council for the year were elected as follows: President, Sir Joseph Lister, Bart., F.R.C.S., D.C.L.; treasurer, Sir John Evans, K.C.B., D.C.L., LL.D.; secretaries, Professor Michael Foster, M.A., M.D., and Lord Rayleigh, M.A., D.C.L.; foreign secretary, Mr. Edward Frankland, D.C.L., LL.D.; council, Mr. William Crookes, Sir Joseph Fayrer, K.C.S.I., Mr. Lazarus Fletcher, Mr. Walter Holbrook Gaskell, M.D., Mr. William Huggins, D.C.L., Lord Kelvin, Professor Alexander B. W. Kennedy, LL.D., Professor Horace Lamb, Professor Edwin Ray Lankester, Professor Charles Lapworth, LL.D., Major Percy Alexander MacMahon, R.A., Professor John Henry Poynting, D.Sc., Professor Arthur William Rücker, Mr. Osbert Salvin, Professor Harry Marshall Ward, D.Sc., and Admiral William James Lloyd Wharton, C.B. The annual dinner of the Royal Society was held at the Hôtel Métropole on the same evening, Sir Joseph Lister, the new President, occupying the chair.

SENSORY NERVES AND MOTOR POWER.

IN a recent communication to the Royal Society Dr. Mott and Dr. Sherrington brought forward facts of the greatest interest and importance with reference to the influence of sensory nerves on movement and nutrition. Claude Bernard had already directed attention to the impairment in the movements of the limbs in frogs and puppies which took place when a limb had been rendered insensitive by section of the sensory roots of the spinal nerves. Dr. Mott and Dr. Sherrington examined the effect of similar lesions in the case of monkeys. If the whole series of sensory roots belonging to a limb is divided—i.e., in the brachial region from the fourth cervical to the fourth thoracic inclusive, and in the lumbar from the second to the tenth post-thoracic inclusive—then from the time of performance of the section onwards as long as the animal may be kept alive the movements of the hand and foot are practically abolished. On the other hand, the movements of the elbow and knee, but especially the movements of the shoulder and hip, are much less impaired. This impairment in motility ensues immediately on section, and in animals kept alive as long as three months after the operation no obvious change took place. The peculiar topographical distribution of the loss of motility already alluded to was constant—that is, the defect increased from the attached base to the free apex of the limb, so that, for instance, while comparatively slight at the hip it was successively greater at the knee and ankle, and greatest in the digits. In this respect it simulated in a curiously close manner the impairment of motility ensuing upon ablation of the limb region in the cortex. In the monkey it is somewhat more severe than the impairment following cortical ablation. But, in spite of this great impairment in motility, forcible and rapid movements could be induced in the animals by causing them to struggle—e.g., as in recovering from ether inhalation. Dr. Mott and Dr. Sherrington infer, from these and other considerations, that associated movements in the limb are comparatively little impaired by loss of the sensation from the limb in which they occur, while the finer movements—those which are represented most liberally in the limb area of the cortex—are extremely severely impaired and in some instances abolished. Yet on electrically exciting the cortex corresponding to the limb deprived of sensation, even when this had persisted for months, no diminution, but rather the reverse, was found in the readiness with which the movement could be evoked. And when

Digitized by Google

epilepsy was produced by the intravenous injection of absinthe the limb deprived of sensation was affected in a manner and to a degree not to be distinguished from its fellow. So that the experiments confirm the view, so firmly held and so strongly emphasised by Dr. Bastian, of the fundamental dependence of the finer movements of the limbs upon the integrity of sensation. The effect of the section of single sensory roots was found to be practically *nil*; some impairment of movement, especially clumsiness, resulted if several roots in relation to a limb were cut. But a degree of impairment, very nearly as great as that produced by section of the sensory roots of the whole series of nerves of the limb, was produced by section of just those sensory roots which supply the apex of the limb—i.e., the hand and foot. If the whole hand or foot be completely deprived of sensation, then the peculiar degree of inability to move the limb already referred to as a result of section of the whole series of roots results. On the other hand, if all the roots are cut except the eighth cervical, which is distributed to the whole extent of the hand, and in the lower limb region all except the sixth post-thoracic, distributed to the whole extent of the foot, a certain degree of impairment in movement results, but it is very slight. No nutritive impairment of the limb could be ascribed to the section of these roots, and certain peculiarities were observed in the resulting degeneration of the cord, of which particulars will be furnished at some future time.

LUXATIO PENIS.

WE have received from Dr. S. Baumgarten of Buda-pest a reprint of a paper he contributed to the *Deutsche Medicinische Wochenschrift*[1] upon a subject to which attention has been recently called in these columns. He alludes to the fact that luxation of the penis is one of the rarest but most important injuries of that organ, and records a case in which the accident happened at the ritual of circumcision in infancy, whilst the reduction of the luxation was not effected until eleven years later. The child was taken to Dr. Baumgarten by the father, who said that his boy had no penis, which had disappeared, as stated, when he was undergoing circumcision at the hands of the constituted official. The primary difficulty in micturition seems to have been at once overcome, but when the child was six months old he was taken to a medical man who succeeded in bringing the glans penis into view. It disappeared again, however, within the course of the day, and the father was counselled to wait until his son was older and the parts more fully developed. From time to time a swelling would appear on the right side of the scrotum, evidently marking the site of the luxated organ. When seen by Dr. Baumgarten the penis was not visible, but the scrotum was well developed. Between the mons pubis and the upper margin of the scrotum were a circular scar and rudimentary penal sheath, with a punctiform opening only admitting the smallest-sized sound which could not be introduced into the bladder. On palpation a cylindrical body could be felt beneath the skin between the scrotum and right thigh, the lower end of which was mobile and shaped like the glans penis. During urination a small swelling appeared in the same region, evidently a kind of accessory pouch between the urethra and the external orifice above mentioned. In the operation which Dr. Baumgarten performed to liberate the penis, he first laid open this pouch and was able to draw out the glans and neighbouring part of the organ, the rest requiring to be detached by the knife owing to adhesions. The formation of a cutaneous covering to the exposed posterior part of the penis required a plastic operation, which was successfully accomplished. Dr. Baumgarten describes the method pursued in the ritual of circumcision, and enumerates the accidents that have been known to follow it, but this is the first case known to him in which luxation of the penis has occurred. He also recounts the facts of five other cases of luxatio penis that have been put on record, in each case due to severe injury and in each an operation was performed to restore the organ to its normal site.

[1] 1895, No. 45.

HEALTH MISSIONERS.

THE Bucks County Council have made a new departure which is, we think, an eminently sensible one. They have established a health mission, and the health missioners are two ladies who go about giving simple lectures on hygienic subjects, and in addition—this is the important part—visit the cottages at the invitation of those who live in them and show them how to apply the rules laid down in the lectures. There is all the difference in the world between an ordinary lecture on cottage hygiene and the practical application of the same such as these two ladies carry on. To bring one's attention to the dangers of dirt; to point out that water, especially at night, is not a poison, or that to allow a child with a high temperature to drink water is not only harmless but beneficial—all this is a work which requires a great deal of tact and sympathy to carry out. An extract from the diary of one of the missioners will show how her work is appreciated:—

Extracts from Health Missioner's Diary (Miss Barker) May and June, 1894.

The Bucks County Council and their workers deserve every credit for the suggestion and the way in which the work has been done, and we hope soon to hear of other councils emulating their example.

THE PORTSMOUTH WATER-SUPPLY.

ONE million and thirty thousand pounds is the price asked by the Portsmouth Water Company, it is understood, for their undertaking, the purchase of which by the town council is being considered by a special committee. One item in the purchase-money that is evoking much criticism is a sum of no less than £14,000 as compensation to the directors and officials, and it is said that of this sum the consulting engineer is to receive £3800, the secretary £3000, the chairman of the directors £1600, and the others £956, £946, £946, and £682 13*s.* 4*d.* respectively.

Digitized by Google

directors receive £126 yearly for their services and the irman £210 on a triennial appointment this is a pretty valuation, if it is accurate. Meanwhile the share-lders of the company, on Thursday, Nov. 28th, held their -yearly meeting. The water rental receipts are £1113 xcess of those of last year, and as compared with four rs ago the increase is £4014, an average at the rate of 00 a year. The full statutory dividend was recommended, 8 4s. were carried to the back dividend account, and a ance of £3490 is taken forward. The directors have tainly followed a course of wisdom all too rare in similar porations with vast interests and responsibilities. For rs they have been buying up the springs and land adjacent the works, in order to control them and place them beyond picion. One stream has been filled up. Now additional wers are being applied for which will include adjacent llages in the supply and the purchase of still more land. e position with regard to the purchase is briefly this. The airman says the company mean to adhere to their former sition—that any terms must be on such lines as are usual the compulsory purchase of water companies. The com-ittee of the council is asking for a reduction in the enormous mpensation demands. At the same time the latter body as laid it down that unless a loan for eighty years can be tained, with five years' suspension of the sinking fund, the egotiations will not be proceeded with.

A LADY EXPLORER IN THE CAMEROONS.

WE do not know whether our readers have perused the escription of Miss Kingsley's travels in the Cameroons gion that recently appeared in the daily journals, but, if , they must have been struck with the courage and re-arkable powers of endurance exhibited on the part of his lady explorer. Miss Kingsley, after reaching Old alabar, proceeded to the French settlement of the aboon, and subsequently explored the gorilla country the interior and went up the Ogowe River to 'Djole. The great difficulties and narrow escapes hat were encountered on that river and its rapids, with he adventures in the Fangwe country, at Lake N'Covi, nd the range of mountains called the Sierra del Crystal, the scent of the Cameroons Peak and the little-known Rumbi ange of mountains, altogether make up, as regards hardship nd peril, one of the most remarkable journeys on record—ertainly as far as any female explorer is concerned. Not-withstanding the great hardships and physical fatigue which Miss Kingsley went through, she appears to have escaped any attack of fever and to have enjoyed good health and to have regularly kept a diary. Miss Kingsley not only seems to possess unique physical powers, but to be endowed with an undaunted spirit and love of adventure, for she intends to return to West Africa in a few months in order to explore other parts. We hope that this lady will publish a detailed account of her travels, and narrate how she managed to maintain health and strength under such exceptional conditions as she has experienced.

THE METROPOLITAN ASYLUMS BOARD AND THE VESTRIES.

A CONFERENCE representative of the metropolitan vestries and district boards was held on Dec. 3rd, the meeting being convened by the Marylebone Vestry, who took the initiative on account of that parish having recently suffered greatly from an outbreak of scarlet fever. The Asylums Board had been invited to send members to the conference, but did not do so. Eventually the following resolution—"That a communication should be addressed to the Asylums Board strongly urging them to take steps to immediately open the vacant beds at the Gore Farm Hospital at Darenth for the purpose of providing the temporary accommodation required by the local authorities for scarlet fever patients"—was unanimously passed; and by a majority of 24 votes a second resolution: "That in the opinion of this conference the authorities making the rate to raise the funds for the requirements of the Metropolitan Asylums Board should be entitled to be directly and adequately represented upon that Board." The checking of infectious disease among a dense population is perhaps the most important problem which the exigencies of civilisation have set us to solve, and we have no hesitation in saying that a very marked cause of the increase in infectious disease and in the mortality from the same has been the Elementary Education Act of 1870. Let any unbiased reader study the report of the medical officer of health of the London County Council dealing with the year 1893, where it is conclusively shown that in respect of both scarlet fever and diphtheria there was a sudden and noteworthy diminution in the prevalence of these diseases during the four weeks of August—i.e., when the London Board schools were shut—and shortly after their opening in September an equally serious increase in both diseases. This being so, the Asylums Board has an ever-vigilant enemy to cope with, and from a letter recently addressed by the clerk to the chairman of the Board it would appear that the Board is doing its best; the difficulty of procuring sites is enormous and the expenses proportionately so. We certainly agree that the authorities who raise the Asylums Board rate should be represented on the Board, but, as far as we can see, that body is fully cognisant of the difficulties it has to meet and the importance of doing so.

WARMING OF PUBLIC VEHICLES.

IT is strange that on our railways, where passengers are confined for hours in draughty carriages, no serious attempts have been made at utilising the waste heat from the engine by a system of steam-pipes or of channels for conveying warmed air, although enough has been attained in the way of experiment to prove the feasibility of the idea, and as yet the companies have contented themselves, but certainly not the public, by serving out a limited number of "foot-warmers," which, if a man have an ordinarily stout pair of boots, and still more, if these be wet, do not even succeed in warming the feet. In tramcars and omnibuses there is, indeed, less necessity for artificial heat, the external cold being rarely so intense as it is on the continent and in America. Still it would be desirable were it only for drying the sloppy floors in wet wintry weather. But in Germany, after trying every imaginable apparatus and source of heat from coal and oil to electricity, the Deutsche Wagenheizungs- und Glühstoff-Gesellschaft in Bremen has achieved a practical success, and their system is already in operation on the Bonn, Mülhausen, Thorn, and Zwickau tramways, and is being tried on those of Hanover, Copenhagen, Mannheim, Munich, and Beuthen as well as on the electric railway at Erfurt. The stove is a cast-iron box, rather less than 1 ft. high, 2 ft. wide, and 8 in. deep, fixed under the seat between the wheel boxes through which the flue is carried with bend to the open. The door of the stove is made to close practically air tight, but fresh air is admitted through the bottom of the stove from beneath the floor of the car. The mouth of this inlet being always directed forward, the draught is increased with the motion of the vehicle, as in the engine-rooms of steamboats. The fuel consists of one to three briquettes, according to the weather, introduced on movable gratings after having been brought to a white heat externally in an ordinary stove. Once ignited, they burn for seven to nine hours and without smoke, at a cost of one penny per briquette, or, including incidental expenses, at an average of

Digitized by Google

7½*d.* per car per day. The entire cost of one such stove, including fixing, &c., is about £2 15*s.* to £3, and with this the temperature can be kept well above the freezing point when that outside is from 15° to 20° C.—i.e., from 27° to 36° F. below freezing—and at a pleasant warmth under fewer degrees of cold.

UNREGISTERED DENTISTS.

AT West Ham Police-court on Dec. 4th Arthur Warren was summoned by Mr. G. R. Matland, a dentist, for unlawfully taking and using the title "Dentist," thereby implying that he was registered under the Dentists Act of 1878. The defendant worked for the American Dentists' Association, and, evidence having been given in support of the charge, he was fined £10 and costs, Mr. Baggallay remarking that in his opinion the whole association was "bunkum." Be this as it may, we congratulate Mr. Matland upon the results of his action. With the question as to whether the defendant knew his work or not we have no concern, but he represented himself as being what he was not—an offence all too common—and is therefore properly punished.

"CLOSED" STOVES AND DIPHTHERIA.

AN outbreak of diphtheria having occurred amongst the children attending the Dunkirk board schools in the Faversham rural district, the medical officer of health has reported that upon inspecting the schools he found that "the closets were common privies and evil-smelling, that a cess-pool was unventilated, and that the schools were very stuffy and unventilated, being warmed by 'tortoise' stoves." The school board decided at once to remedy the defects in the closet arrangements, but, failing to see how the schools being warmed by "tortoise" stoves could be held responsible for their being "stuffy and unventilated," the members naturally object to being ordered to remove the present heating arrangement. The "tortoise" was the first of the firebrick-lined stoves, which, on account of their great heating power and economy in the use of fuel, have become very popular. Like all other closed stoves, requiring very little air they are not so efficient as ventilators as open fireplaces, and where they are used some other means of supplying fresh air to the rooms is absolutely necessary. It does not follow, however, that the best remedy for lack of ventilation is to remove the stoves and substitute the extravagant firegrate. In the Dunkirk schools the children are stated to be "crowded together," and it would seem that more adequate air space and freer ventilation are the real requirements, and Dr. Newsholme in his "School Hygiene" has pointed out a simple method by which closed stoves of the "tortoise" class can be made not only to assist ventilation but also to warm the incoming air. Given an unrecognised case of diphtheria, the conditions existing in and around the schools are adequate to explain the spread of the disease whatever the mode of heating adopted, and it seems rather harsh that the simple and economical "tortoise" stove should bear such a large proportion of the blame as a cause of the epidemic.

THE LANCASHIRE ASYLUMS BOARD AND THE PENSION SCHEME.

THE Lancashire Asylums Board met last week at Preston and adopted a pension scheme, combined with a scale of salaries. A committee had been appointed for the purpose which had carefully considered the reports from the various asylums throughout the kingdom, and the scheme recommended was based on the best lines of those reports. The committee adopted the age of fifty-five years at which pensions should begin. The scale of pensions was elastic, tarting as low as one-third of the salary alone, and extending to the legal limit of two-thirds of the salary and emoluments combined. The committee thought also that the actual pension in each case should be left within the limits named for the committee of each asylum to recommend. Pensions at an earlier age than fifty-five might be given in cases of incapacity arising, and when the committee thought there was sufficient reason for an exception compulsory resignation at sixty might be broken through. We are pleased to note the adoption of these recommendations to a class of public servants who are not overpaid, and whose monotonous duties are not of the most pleasant description, and we trust they will be faithfully carried out by succeeding asylum boards. In these anti-pension days we are cognisant of one medical superintendent of a Lancashire county asylum who had difficulty in obtaining a pension at all, although he was promised it by the old authority under whom he took office—namely, the visiting justices; but the change to the county council nearly lost him a pension, and what he did get was £200 per annum less than that to which he was entitled according to scale.

THE important discussion on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues, as in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, &c., which commenced on Nov. 26th at the Royal Medical and Chirurgical Society, 20, Hanover-square, will be continued on Tuesday next, Dec. 10th.

MR. SYDNEY HOLLAND, the Chairman of the Poplar Hospital for Accidents, makes an earnest appeal in the daily press for £3000 to build an isolation block. Scarlet fever has broken out in the wards. The Asylums Board hospitals are full, and the patients have to be sent back to their homes to spread infection there.

AT the Sanitary Institute, Margaret-street, W., on Wednesday next, a discussion will be opened by Sir Douglas Galton on the Lessons to be Learned from the Experimental Investigations by the State Board of Health of Massachusetts upon the Purification of Sewage. The chair will be taken at 8 P.M.

SPECIAL REPORT ON THE BLACKFRIARS SALVATION ARMY SHELTER PROSECUTION.

WE present to our readers Dr. Waldo's report upon the important police-court proceedings taken by the Vestry of St. George-the-Martyr against the Salvation Army in the matter of a shelter in the Blackfriars-road.

To the Chairman and Members of the Vestry of St. George-the-Martyr, Southwark.

MR. CHAIRMAN, LADIES, AND GENTLEMEN,—You will naturally expect a few words from me, as your medical officer of health, upon the important police-court prosecution lately undertaken by your vestry against the superintendent of the Salvation Army shelter in the Blackfriars-road.

First of all the vestry may be congratulated upon the fact that a danger to the common safety, although not altogether abolished, has, nevertheless, been brought nearer a proper sanitary control. In this way the vestry of St. George-the-Martyr has carried out a public-spirited policy which deserves the thanks of every local authority in London. The history of the facts which led up to the Blackfriars prosecution is simple. For three years past I have called attention in my annual reports to the dangers arising from the presence of these overcrowded and ill-regulated pseudo-charities in your midst. The dangers in question may be divided under two heads, according to their injurious effect: (1) directly on the inmates of the shelter; and (2) indirectly on the outside public.

Copies of the reports dealing with these points have been

Digitized by Google

duly laid before the Local Government Board and the London County Council. In 1893 the Government sent Dr. Airey to inspect the metropolitan night shelters, but his report has not been made public, neither has the Local Government Board, so far as I know in my official capacity, taken any further steps in the matter, nor has the London County Council interfered. This was the position of affairs in the summer of the present year, when an outbreak of small-pox occurred in your parish, and out of forty-four cases no less than nine were traced directly to the shelter. I thereupon applied one night at the shelter for admission, which was refused, and I then drew the attention of your Public Health Committee to the occurrence. I was next instructed by your committee to apply to the local magistrate for a warrant to enter the shelter on the night of July 8th. As a result of that visit your vestry obtained a summons asking for prohibition against future overcrowding. After a protracted hearing, extending over four months, the magistrate, Mr. Slade, granted the order asked for, and stated that personally he would not regard the presence of anything under 550 inmates as overcrowding. It is worthy of note that, despite the strong assertions of defendants' counsel in the course of the trial, no appeal has been made against the decision of the magistrate.

It may be well to add a few remarks upon the scientific evidence furnished in court. The chemist who acted for your vestry found 75 parts of carbonic acid gas per 10,000 of air in what was known as the "twopenny overflow bunk-room," whereas the usual limit regarded by sanitary officers as permissible is 6 parts of carbonic acid gas per 10,000. The chemist for the defence, Mr. Wanklyn, stated that the figure, 75 per 10,000, was impossible. Without entering at length into the matter I may say that Mr. Wanklyn's view runs counter to all standard scientific teaching and experience. Pettenkofer, for instance, one of the greatest living authorities on the subject, found 73·2 parts per 10,000 in a girls' school. Mr. Wanklyn tested the air in the "twopenny overflow bunk-room," and found 8·6 parts of carbonic acid gas per 10,000. His figure of 8·6 offers a startling contrast to our figure of 75. It is easily explained, however, by the fact that Mr. Wanklyn took his sample at an earlier hour of the night, and that between our visit of July 8th and the date of his experiment extensive alterations had been carried out in the ventilation of the particular room in question. This dispute between the chemists is unfortunate, because it tends to draw attention away from the main issue. It is entirely unnecessary, moreover, for I am prepared to state from the evidence of my own senses, apart from any chemical examination, that the air of the "twopenny overflow bunk-room" on the night of July 8th was not only dangerous to health, but also to life itself. In this view I am supported by Dr. Walsh, who was with me on the night of the visit. Besides, a foul condition of the air followed as a necessary result from the gross overcrowding and the defective ventilation of the place.

I may add that not a single medical officer of health could be found to give evidence for Mr. Booth in favour of the sanitary condition of the shelter. On the other hand, my contentions as to unwholesomeness were supported by no less than five metropolitan medical officers of health, to say nothing of independent medical and scientific testimony. According to my estimate the Blackfriars shelter was able to accommodate 401 persons. On the night of entry I found 1031. On two other occasions, on the admission of the shelter officials, the numbers varied from 743 to 1045. When the magistrate, therefore, placed the limit at 550 he convicted the Blackfriars shelter authorities of gross overcrowding. As regards the decision of Mr. Slade, I may say that in my opinion the vestry is not bound to accept the figure of 550, in the absence of any knowledge upon what basis that number has been fixed. At the same time, it would, of course, be unwise to adopt any other standard in any possible future proceedings. For my own part, I see no reason why the vestry should lessen the reasonable demand for 30 square feet floor-space and 300 cubic feet air-space for each inmate. This is the minimum I regard as necessary in the presence, I need hardly add, of free ventilation.

The weak point in the present position appears to lie in the fact that your officers have no right of entry at night for purposes of inspection. As a matter of fact, I myself was refused admission in June last, and even when armed with a justice's warrant I obtained an entrance only in the face of forcible resistance and under the threat of bringing up a strong force of police.

In conclusion, it may be confidently expected that the action of your vestry will sooner or later bring these shelters and other night refuges of a similar nature within the control of the Common Lodging-house Acts.

Your obedient servant,

F. J. WALDO.

The Vestry of St. George-the-Martyr is to be heartily congratulated upon the success of its spi rited action. That such shelters, while irresponsible in their management to proper sanitary authority, must be sources of danger to the community is self-evident, and the sooner "General" Booth's disciples see this the better for us all—and probably the better for them now that a precedent has been established for opening their eyes in a police-court. We note with pleasure that Dr. Waldo's report was received in a very proper spirit by his vestry, who passed a vote of thankful appreciation of his efforts.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of the Royal College of Surgeons of England was held, at 5.30 P.M., on Dec. 4th, at 25, Grosvenor-street. Mr. George Pollock, the President, occupied the chair. There was a large attendance. The minutes of the preceding meeting were read and confirmed.

The Honorary Secretary (Mr. Percy Dunn) reported that he had received a reply from the Council of the Royal College of Surgeons of England in respect to the resolutions which the Committee had passed at the last meeting and which had been laid before the Council. The reply was to the effect that the resolutions had been received. After some discussion it was unanimously resolved:

"That the Committee of the Association of Fellows of the Royal College of Surgeons of England regrets that the Council of the Royal College of Surgeons of England has not discussed the important suggestions made by the Committee for the more satisfactory conduct of the half-yearly meetings of the Fellows of the College, but considers it desirable, owing to several important questions being set down for discussion at the half-yearly meeting of Fellows, to postpone further action for the present."

The Committee then received a deputation from the Civil Rights Defence Committee, headed by Lord Stamford, in reference to the case of Mr. R. B. Anderson.

The agenda for the annual general meeting of the Association, which had been fixed for Dec. 11th, were then determined. These consisted of the President's address, the auditor's report, the election of officers for 1895–96, the case of Mr. R. B. Anderson and the appointment of representatives of the Association on the Civil Rights Defence Committee, and other business.

At the instance of Mr. T. Holmes, the question of the attitude of the Association in regard to the claims of the Members of the College, as expressed in the resolutions passed at the last annual meeting of Fellows and Members of the College, was again brought under the notice of the committee as these resolutions would probably be brought before the Fellows for discussion at the half-yearly meeting in January next. It was, however, decided that the advocacy of the Members' claims could not be undertaken by the Association, a policy which had been for some considerable time pursued in accordance with the wishes of the members of the Association, but it was pointed out that the adoption of this policy was not intended to fetter individual action or expression of opinion.

This concluded the business of the meeting, and the committee adjourned.

FOOTBALL CASUALTIES.—On Saturday last a member of the Lancaster Rugby Football Team, while playing in a match between the Royal Grammar School team, Lancaster, and the Christ Church Hornets, fractured his fibula.—During a game at Pontypool on Tuesday last a player sustained a fracture of three of his ribs.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 5620 births and 3639 deaths were registered during the week ending Nov. 30th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 22·1 to 19·0 per 1000, further fell last week to 17·9. In London the rate was 17·3 per 1000, while it averaged 18·4 in the thirty-two provincial towns. The lowest rates in these towns were 11·3 in Croydon, 12·2 in Brighton, 12·5 in Portsmouth, and 13·1 in Bradford; the highest rates were 20·1 in Manchester, 22·7 in Preston, 23·3 in Liverpool, in Salford, and in Oldham, and 29·0 in Blackburn. The 3639 deaths included 529 which were referred to the principal zymotic diseases, against 522 and 548 in the two preceding weeks; of these, 211 resulted from measles, 93 from diphtheria, 65 from "fever" (principally enteric), 63 from whooping-cough, 48 from diarrhœa, 46 from scarlet fever, and 3 from small-pox. No fatal case of any of these diseases was recorded in Brighton; in the other towns they caused the lowest rates in Croydon, Derby, Hull, and Gateshead, and the highest rates in Birmingham, Salford, Wolverhampton, and Blackburn. The greatest mortality from measles occurred in Birmingham, Manchester, Swansea, Wolverhampton, and Salford; from whooping-cough in Wolverhampton and Leeds; and from "fever" in Norwich, Burnley, Sunderland, and Wolverhampton. The mortality from scarlet fever showed no marked excess in any of the large towns. The 93 deaths from diphtheria included 63 in London, 6 in Birmingham, 3 in West Ham, and 3 in Sheffield. Two fatal cases of small-pox were registered in West Ham, and one in London, but not one in any other of the thirty-three large towns. There were 79 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Nov. 30th, against 78, 86, and 89 at the end of the three preceding weeks; 9 new cases were admitted during the week, against 14, 23, and 20 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2799, against 2847, 2845, and 2807 on the three preceding Saturdays; 320 new cases were admitted during the week, against 349, 298, and 296 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 447 to 327 in the three preceding weeks, further fell to 285 last week, and were 146 below the corrected average. The causes of 51, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Oldham, Leeds, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Norwich, Blackburn, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 21·4 to 18·1 per 1000, further fell to 17·4 during the week ending Nov. 30th, and was 0·5 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·4 in Leith and 16·7 in Paisley to 21·1 in Dundee and 24·0 in Perth. The 503 deaths in these towns included 18 which were referred to diarrhœa, 11 to whooping-cough, 8 to scarlet fever, 6 to diphtheria, 5 to "fever," 1 to measles, and not one to small-pox. In all, 49 deaths resulted from these principal zymotic diseases, against 52 and 48 in the two preceding weeks. These 49 deaths were equal to an annual rate of 1·7 per 1000, which was 0·9 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The 18 fatal cases of diarrhœa showed a further increase upon the numbers recorded in recent weeks, and included 7 in Aberdeen, 5 in Glasgow, and 4 in Dundee. The deaths referred to whooping-cough, which had declined from 21 to 10 in the three preceding weeks, were 11 last week, of which 9 occurred in Glasgow. The fatal cases of scarlet fever, which had been 9 and 12 in the two preceding weeks, declined to 8 last week, and included 4 in Edinburgh and 3 in Glasgow. The deaths from diphtheria, which had declined from 8 to 3 in the three preceding weeks, rose again to 6 last week, of which 2 occurred in Dundee. The 5 fatal cases of "fever" showed a decline of 3 from the number in the preceding week, and included 2 in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 134 and 125 in the two preceding weeks, further declined to 107 last week, and were 57 below the number in the corresponding week of last year. The causes of 35, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·1 and 23·5 per 1000 in the two preceding weeks, further rose to 27·1 during the week ending Nov. 30th. During the past nine weeks of the current quarter the death-rate in the city has averaged 24·5 per 1000, the rate during the same period being 18·2 in London and 17·5 in Edinburgh. The 168 deaths registered in Dublin during the week under notice showed an increase of 8 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 6 and 10 in the two preceding weeks; of these, 4 resulted from "fever," from whooping-cough, 1 from measles, 1 from scarlet fever, 1 from diphtheria, and 1 from diarrhœa. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 2·5 in London and 1·3 in Edinburgh. The deaths referred to different forms of "fever," which had been 2 and 3 in the two preceding weeks, further rose to 4 last week. The 2 fatal cases of whooping-cough exceeded the number recorded in any recent weeks, while the mortality from scarlet fever and from diarrhœa showed a decline. The death from measles was the first during the current quarter. The 168 deaths in Dublin last week included 30 of infants under one year of age, and 41 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Five inquest cases and 7 deaths from violence were registered; and 54, or nearly a third, of the deaths occurred in public institutions. The causes of 11, or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF MEDICAL STAFF.

THE following officers have arrived from India:—Surgeon-Majors Leader, Carleton, and Barrington. Surgeon-Major Nealon has been invalided from Ceylon. The following officers have embarked for India:—Surgeon-Majors Nicholson and Kerin, and Surgeon-Lieutenants Taylor and Morgan. Surgeon-Major Fox has embarked for a tour of service in Jamaica.

ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel James Macartney, M.D., from half-pay, to be Brigade-Surgeon-Lieutenant-Colonel, Supernumerary to the establishment, with precedence next below Brigade-Surgeon-Lieutenant-Colonel J. Barry, M.D. Surgeon-Captain Alfred Wright, from the Seconded List, to be Surgeon-Captain, vice P. B. Skerrett, retired.

INDIA AND THE INDIAN MEDICAL SERVICE.

Surgeon-Captain R. Bird is appointed to act as Civil Surgeon of Bankura. Surgeon-Captain W. Vost, Civil Surgeon, on return from temporary military duty, is posted to the Bahraich District. Surgeon-Major F. P. Nichols is appointed to hold collateral charge of the Civil Surgeoncy at Shwebo. Surgeon-Lieutenant Hugh Bennett is appointed to the Officiating Medical Charge of the 7th Bombay Infantry; Surgeon-Lieutenant Vivian Bennett to the Officiating Medical Charge of the 3rd Bombay Infantry; and Surgeon-Lieutenant Evans to the Officiating Medical Charge of the 20th Bombay Infantry. The services of Surgeon-Captain B. C. Oldham and of Surgeon-Captain F. P. Maynard, Officiating Resident Physician, Medical College Hospital, and Professor of Pathology, Medical College, Calcutta, are placed at the disposal of the Inspector-General of Gaols.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet-Surgeons:

THE SERVICES.

MOVEMENTS OF [illegible]

THE following officers have embarked ... Majors Leader, Carleton, and ... Nenlon has been invalided from ... officers have embarked for India—... and Kerin, and Surgeon-Lieutenant ... Surgeon-Major Fox has embarked ... Jamaica.

ARMY MEDICAL [illegible]

Brigade-Surgeon-Lieutenant-Colonel ... M.D., from half-pay, to be ... Colonel, Supernumerary to the ... cedence next below Brigade-Surgeon ... J. Barry, M.D. Surgeon-Captain ... Seconded List, to be Surgeon-Major, ... retired.

INDIA AND THE INDIAN [illegible]

Surgeon-Captain R. Bird is ... Surgeon of Bankura. Surgeon-Captain ... geon, on return from temporary ... the Bahraich District. Surgeon-Major ... appointed to hold collateral charge ... at Shwebo. Surgeon-Lieutenant-Colonel ... to the Officiating Medical Charge ... Infantry; Surgeon-Lieutenant ... Officiating Medical Charge of the ... Surgeon-Lieutenant Evans to the ... of the 20th Bombay Infantry. ... Captain B. C. Oldham and ... Maynard, Officiating Residency ... Hospital, and Professor of Pathology ... Calcutta, are placed at the disposal ... General of Gaols.

NAVAL MEDICAL [illegible]

The following appointments are [illegible]

A. M'Adam to the *St. Vincent*; A. Patterson to *Blake*; J. L. Sweetman to the *Pembroke* (additional) Chatham Yard; A. Gorham to the *Majestic*; J. Lyon he *Magnificent*; H. A. W. Richardson to the *Impregable*; A. W. Russell to the *Royal Sovereign*. Staff-Surgeons: J. Dudly to the *Empress of India*; H. E. Marsh to *Rupert* (additional) for Gibraltar Hospital; A. Kidd to *Ganges*. Surgeons: J. E. Coad to the *Majestic*; C. ckland to the *Magnificent*; E. D. Minter to the *Rupert*; E. Rock to the *Blake*; F. J. Barter to the *Empress of ia*; E. P. Mourilyan to the *Rupert* (additional) for raltar Hospital.

ARMY MEDICAL RESERVE OF OFFICERS.

urgeon-Captain William Vernon, having resigned his unteer appointment, ceases to be an Officer of the y Medical Reserve of Officers.

VOLUNTEER CORPS.

rtillery: 1st Worcestershire and Warwickshire: Sur-n-Captain R. W. Edginton, M.D., to be Surgeon-jor. *Rifle*: 1st (Pembrokeshire) Volunteer Battalion the lsh Regiment: Alexander James Anderson, M.B., to be geon-Lieutenant. 1st Volunteer Battalion the Essex iment; Adam Robert Hamilton Oakley, Gent., late geon-Captain 2nd London Volunteer Rifle Corps, to be geon-Lieutenant. 13th Middlesex (Queen's Westminster): geon-Lieutenant A. T. Collum resigns his commission. l Volunteer Battalion the Manchester Regiment: Surgeon-otain T. Carr, M.B., resigns his commission.

THE LATE EXPEDITION IN MADAGASCAR.

THE recent debate in the French Chamber on the expedition Madagascar and the new treaty consequent on the capture the capital by the French force, with the establishnt of a French protectorate, naturally gave rise to a good l of political excitement and public interest. There is no ubt that the army had to encounter very great and expected difficulties of a climatic and topographical kind their campaign in Madagascar, and that the expeditionary ce and its commander deserve great credit for their roism, endurance, and discipline in the field, and for their y orderly and humane conduct when they had attained eir object by the capture of Antananarivo and the bmission of the Queen. The admirable qualities of e French soldiers have been conspicuous on this casion, and they have been heartily recognised in is country. The sacrifices of life and health have, wever, been very large. M. Vigne said that the ganisers of the expedition to Madagascar had certainly no ght to the gratitude of the nation—on the contrary, the tion should demand of them an account of so many lives ving been sacrificed. He then entered into particulars illusative of the shortcomings, defective hygienic and medical rangements, and bad management of the expedition. . Pier Alype also dwelt upon the faults committed at e commencement, for which he held the Marine Department more especially responsible. M. Cavaignac, the French inister of War, stated that 17,500 men had been sent to ajunga to form the expeditionary corps. Three thousand d died in Madagascar, 6000 had already returned to rance, and 3900 more were to be brought back to France ithout delay. To the list of deaths in Madagascar it was ecessary to add that 300 had died on the voyage home, and bout 100 in the French hospitals after their arrival. The otal number of deaths was therefore about 3500. The reatest mortality had been caused, M. Cavaignac said, by he employment of European troops in unloading barges and onstructing roads. He warned the Chamber against seeking capegoats or making the Madagascar question a subject of ecrimination. The difficulties had been of an exceptional ind, but he admitted that faults had been discovered in rench organisation which it was necessary to reform, and lescribed or explained many of the exceptional and adverse conditions under which the expedition had laboured. The Chamber eventually passed a resolution by a large majority pproving the declarations of the Government, and sending ts congratulations to the soldiers and their chiefs. Notwithstanding this, it is evidently the intention of the Government to organise in future a colonial army and to introduce a great many improvements in military administration in connexion with any future expeditions of this nature.

THE NEW COMMANDER-IN-CHIEF.

It will not have escaped our readers' attention that Lord Wolseley, in his speech at the Royal United Service Institution on the 28th ult., in connexion with Colonel Balfour's address on the Tactical Training of Officers of Volunteers, made some observations which were quite at one with those which he had previously made, and are sufficiently indicative of what may be expected during his *régime*. Although we have not come to that period when we can, on the one hand, lay down dictatorially to a Volunteer officer that if he does not pass certain examinations in tactics his services will be dispensed with, Lord Wolseley remarked, on the other hand, that whenever we get a bad commanding officer "we should do with the Volunteers what I hope will always be done with the line, that we should get rid of him." And he went on to add, with regard to incompetent commanding officers, that we should say, "You have done your best, sir, but your best is not good enough for us, and you must go." It is clear that the new Commander-in-Chief intends, as far as possible, by selection of the best and removal of the worst officers, to try, at any rate, to make the army of the future a more perfect fighting machine. His lordship clearly has no belief in one man being as good as another, or "the much of a muchness" principle. It may be assumed, we think, from the foregoing that what applies to regimental corps will also apply to departments, and that for the future there will be, as far as Lord Wolseley is concerned, a greater application of the principle of selection in the Army Medical Service than has been the case with his predecessor in the office of Commander-in-Chief.

ARMY MEDICAL STAFF EXAMINATION.

An examination of candidates for seventeen commissions in the Army Medical Staff will be held at the Examination Hall, Victoria Embankment, W.C., on Feb. 7th, 1896, and following days. Applications for admission to the competition should be made in writing, without delay, to the Director-General, Army Medical Department, 18, Victoria-street, London, S.W.

The *Army and Navy Gazette* states that Surgeon-Colonel T. Maunsell, now Officiating Principal Medical Officer of the Bengal Army Corps, will, pending promotion to surgeon-major-general's rank, vice Inkson, succeed the latter officer, on his retirement by age, at Malta. Surgeon-Colonel J. Maturin, on promotion, has taken up the duties of Principal Medical Officer, Colchester. Brigade-Surgeon-Lieutenant-Colonel T. O'Farrell will, when gazetted to higher rank, succeed Surgeon-Colonel Churchill in the Home District on the latter's probable transfer to India, vice Maunsel. This will bring about no less than four principal medical officers in the Home District in three years.

On Nov. 29th 184 invalids arrived at Netley from India by H.M.S. *Malabar*. A further large number of invalids is expected to arrive at the Royal Victoria Hospital, Netley, ex s.s. *Dilwara*, shortly.

TORQUAY MEDICAL SOCIETY.—At a meeting of this society, held on Nov. 20th at the Torbay Hospital, the president, Mr. R. Pollard, M.B., brought the case of Mr. Anderson of Tobago before the notice of the members present, and the following resolutions were carried unanimously: First, "That on the grounds set forth in the interim reports of the Civil Rights Defence Committee the members of the Torquay Medical Society present desire to express their entire concurrence with the Civil Rights Defence Committee in earnestly inviting members of Her Majesty's Government, Members of Parliament, public men, and public bodies, both medical and lay, to coöperate with the committee in defence of the chartered and statutory rights of medical men, and of the ancient rights and liberties of British subjects." Secondly, "That this society, having considered the case of Dr. Anderson, desires to express its sympathy with him under the wrongs he has sustained, and recommends for approval by the council that a sum of five guineas be contributed in the name of the society to the fund being raised in support of Dr. Anderson's appeal." The sum of five guineas was subsequently forwarded to the Civil Rights Defence Committee, with a further sum of ten guineas subscribed by medical men in Torquay; and a memorial signed by most of the medical men in Torquay has been forwarded to their Member of Parliament, Captain Philpotts, R.N., asking him to afford the Civil Rights Defence Committee his coöperation and support.

"'RETURN' CASES OF SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—The interesting and carefully considered paper by Mr. T. W. Thompson in THE LANCET of Nov. 23rd appears opportunely at a time when the profession generally is interested in the subject of the isolation of infectious diseases, and especially so to those who are in any way connected with the management of infectious hospitals. At the present time the subject is particularly interesting to me, on account of a case which has occurred in my own household, and which I think may be of some general interest to the profession as an illustration of a "return" case where careful precautions were adopted with the view of preventing the occurrence of such an unfortunate circumstance. To make matters clear I had better explain that my house consists of the ground floor, first floor, and second floor; the nurseries, day and night, adjoining one another on the second floor. I have two children; C., the elder, aged six and a half years, and E., the younger, aged five. I will put the case more fully immediately, in a tabular form, but will summarise it briefly as follows. C. contracts scarlet fever, and within thirty-six hours of the onset is taken to an infectious hospital in order to avoid any risk to E., who is a delicate child and has had middle-ear mischief on two occasions, and who could not be sent away from home. The nurseries are stripped, disinfected, and repapered, and the furniture all carefully washed with a strong disinfectant. E. (the younger child) then returns to the nurseries and remains well until eleven days after joining her sister on the return of the latter from the hospital. C. (the elder child) remains at the Fever Hospital between seven and eight weeks, and is then discharged. All clothes used at the hospital are left there, and my wife took a fresh set of clothes, which were put on the child immediately after a bath, and she was at once brought home, the weather being too cold to send her away. E. (the younger) is sent for a short holiday, and does not join her sister until three days later. Eleven days after the sisters have come together E. contracts scarlet fever, from which she is at the present time suffering.

Probably the following tabular statement will make the case clear:—

1st week, beginning Tuesday, Sept. 3rd	C—— and E—— go for a holiday to some friends.
2nd week, beginning Monday, Sept. 10th	C—— and E—— return home. The same evening C—— contracts scarlet fever. On Sept. 11th C—— is taken to the infectious hospital.
3rd week	The nurseries are closed, and E—— is kept on the ground and first floors.
4th week	The nurseries are stripped and fumigated with chlorine; all paint and furniture are washed with a strong disinfectant, and the nurseries are re-papered.
5th week	E—— again occupies the nurseries.
6th "	
7th week	E—— goes away for a holiday at the seaside.
8th "	
9th week: Tuesday, Oct. 29th	E—— returns home and occupies the nurseries.
" Friday, Nov. 1st	E—— is sent from home to some friends, and C—— returns from the Fever Hospital.
10th week: Monday, Nov. 4th	E—— returns home and joins her sister C——.
11th week: Saturday, Nov. 16th	E—— contracts scarlet fever.

I cite these cases as not in any way reflecting upon the management of the Fever Hospital, where my child was most carefully and kindly attended to, and where the officers, knowing the reason for which I had sent the child to the hospital rather than nurse her at home, had been particularly careful to keep the child for what was considered a sufficiently long period and up to a time when they thought there was no risk. In fact, as an extra precaution I know she was kept a few days after the time when she was considered safe and fit to be discharged.

I have sent you a note of this because I think there can be little doubt that it was a "return" case, and that in the case of the younger child the scarlet fever was not contracted from another source of infection. I am aware of the difficulty, in fact the impossibility, of being certain upon the latter point, but I am not aware that child ever came into contact with another case of fever; and between the time the elder child left the h and the day the second one took on the fever I had a case of the disease in question.

I think medical officers of infectious hospitals are fully aware of the risks attending the discharge scarlet fever patients and that they do not deserve the that is frequently attached to them. I also quite agr Mr. Thompson when, in his concluding paragraph, "that although a certain proportion of 'return' cas of course at divers times and places be due to circ in the discharge of patients, or to some other culpable maladministration, whether on the part hospital officials or of those responsible for the disi of the patients' dwellings and effects, there are, never in all probability some more obscure factors at work— perhaps closely bound up with the natural history of fever."

I am, Sirs, yours faithfully,

Mosley-street, Manchester, Nov. 27th, 1895. THOMAS H

THE INFECTION OF MILK.

To the Editors of THE LANCET.

SIRS,—A recent theft of milk[1] leads me to write If this man had not been detected in the act of ste milk, no one would have been one whit the wis probably the whole neighbourhood would have been— I write may yet be?—infected. For here is a man with his wife and having three children ill with scarl all of them occupying one small room, who goes out jug, probably a dirty one or otherwise infected, and into a neighbouring dairyman's churn. It would be ing to know what became of the rest of the milk in the Scarlet fever in this case might, or may, have been through the entire district, and in this particular in the origin in all probability would never have been tr the thief had not been caught white-handed. Thi shows one of the many great difficulties of detecti cause of infectious diseases. I would now like to po that until we have a proper sanitary inspection and re tion of all places where milk is sold as well as whe produced our present system of sanitation is almost I have for some time past been watching some probable causes of milk infection in London. The stations in the country and elsewhere may possi thoroughly inspected—such, for instance, as the reg inspection of the cows, the chemical and bacteri examination of the milk, water, and various utensils the health of the servants and the surrounding inha But what is the use of all this, if the milk cans and utensils are left at any time open and exposed to the accessible to anyone either in course of transit or a retail establishment in London or elsewhere.

The causes of infection are numerous. The can utensils are left uncovered, and exposed to the dirt not only of the houses and small retail but also to the clouds of dust blowing from the without. You may often enter the dairies only the milk uncovered upon the counter or, often, upo floor when the dairy is being swept out. The feet of cu ous customers, and the dresses of women in parti convey unheard of abominations from the public stre the floor of the dairy, and in dry weather this filth is w up and thus wafted all over the place only to settle in the milk. I have occasion repeatedly to visit one largest railway stations for the reception of milk in metropolis, and I have seen the porters sweeping refuse from the station platform and putting it in empty milk cans standing on the platform. I have them with hot water in these cans during the winter dipping a dirty broom into them and washing grease filthy parts of the platform and then again transferring dirty broom to the milk cans. I could of course mul these examples almost indefinitely, but the foregoing are patent that it must be clear to everyone that until the milk properly stored, not only in the country, but in towns, at dairies and retail establishments the present condition is more than useless—it is mischievous.

I am, Sirs, yours truly,

London, Dec. 3rd, 1895.

"THE BATTLE OF THE CLUBS."

To the Editors of THE LANCET.

SIRS,—It is gratifying to know that the profession has gained a great victory at Portsmouth, and the effect, I hope, will be to encourage holders of club appointments in other towns to combine together and insist on fair and adequate remuneration for services rendered. There is one reform which is most urgently needed with respect to the tenure of club appointments. In the vast majority of club rules it is definitely stated that the medical officer shall hold office "during the pleasure of the 'court.'" This unfair rule enables a club to dispense with the services of their medical officer without assigning any reason and at a short notice. It is within my own knowledge that this has been done. It is unjust, because in many instances the medical officer has no notice of the meeting which is called for the specific purpose of dispensing with his services. He is only made aware of what has been done when he receives the official intimation that his services will not be required after a certain date. I suggest that an association of club medical officers should be formed to deal with this and other unjust rules. Justice demands that a medical officer should have every opportunity of answering any complaints that have been made against him, and also that he should have an opportunity given him of attending any meeting called to discuss the question of his dismissal.

I am, Sirs, yours faithfully,

Cardiff, Nov. 30th, 1895. T. GARRETT HORDER.

"THE ADMISSION OF WOMEN TO THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—Dr. Walter Carr's letter in your last issue is amusingly persuasive, but not convincing; its gallantry is admirable, its arguments (not quite) irresistible. Because A drives in the thin end of a wedge it is no reason that B, who has far more interest in the operation and is a better judge of its expediency, should force it further in. If the question had had to be decided in the first place by the general body of the profession, instead of by certain examining bodies, the movement would probably never have got a start. And why should not this female craze die out in course of time, just like other female crazes, which are for the most part periodic and recurrent? Take, for instance, examples to be found in the essayists of last century. Goldsmith ridiculed in his happiest way the fashion of women of the day to imitate male attire. Has not this disappeared and cropped up again. Steele also devotes one of his "Tatlers" to the fondness of ladies (!) of attending trials for rape. Is not this exactly paralleled by the attendance at the divorce court to-day? And in all probability we should find in the old essays an account of the attempt by women to enter the medical profession then if the means of doing so had been like what they are now. When the times again become less sophisticated we are not likely to hear so much of these foolish movements. To know these Aspasias of the Marylebone and Gray's Inn Roads is to—well, is, no doubt, a liberal education. By what blandishments or bribery the large array of signatures was obtained to the petitions to the two Royal Colleges no one would think of inquiring. The method by which women gained an entry into the British Medical Association, "by the practically unanimous vote of 16,000 members," as the *British Medical Journal* has it, is a curious historical incident. Let us be warned in time and follow the wise example of Ulysses in his adventure with the Sirens, remembering that the encouragement and admission of women are making our profession the laughing-stock of sensible people of both sexes. Think, Sirs, of what would come to pass in the constitution of your paper should this peculiar movement make much further headway. Instead of an occasional paragraph on the wearing of stays, &c., you would perhaps be tempted to sacrifice dignity to popularity and insert a weekly article on Fashions and perhaps also a column of Gossip, to please your numerous feminine readers.

I am, Sirs, yours truly,

F. LUCAS BENHAM, M.D. Lond.

Elizabeth-street, S.W., Dec. 2nd, 1895.

"ADENOID GROWTHS IN THE PHARYNX."

To the Editors of THE LANCET.

SIRS,—The practical points in Sir William Dalby's article on the above subject in THE LANCET of Nov. 30th must have been read with much satisfaction by most who are interested in this affection. I know no more satisfactory operation in surgery than that for the removal of adenoids when undertaken before it is too late and thoroughly carried out. In order to thoroughly carry it out two points must mainly be observed: first, the patient must be anæsthetised for a sufficient length of time, and, secondly, more than one instrument must be used. To fulfil the first point it is, in my opinion, necessary that some anæsthetic having a longer action than nitrous oxide gas should be employed. Some time back, when this gas was strongly recommended for this operation, I gave it a trial in several instances, and though I do not think I am usually considered a slow operator, and though I quite admit it gives ample time to tear out a few masses with the forceps or roughly scrape out tissue with the curette, I am convinced the interval is not long enough to complete what I would term the "toilet of the naso-pharynx"; in two of my own cases when using the gas an unseemly struggle between operator and patient on the table wound up the proceedings. Then as to the second point—that more than one instrument should be employed—I cannot understand after a considerable experience how one operator uses the forceps only, another the curette, whilst the third always professes that his own finger-nail or the steel nail suffices. I admit that every now and then one finds a little soft, succulent overgrowth of tissue which one can break down and remove with the finger-nail at the time of examination without any anæsthetic, local or general. That I may now and then do; but in an average case I always make a point of employing all three instruments. Beginning with the forceps I remove all the larger masses, then I scrape well round with the curette, and complete the "toilet of the naso-pharynx" with my finger-nail. I almost always use chloroform, under which the patient is fully put by a very experienced anæsthetist; then the lint or handkerchief is removed and no more is administered. One practical point is important, and that is that the tonsils (faucial) should not be removed at the same sitting; where their size renders it necessary that they should be dealt with surgically, they should be removed first, two or three weeks before the adenoids; for tonsillotomy no anæsthetic, local or general, is required. I never use any. Sir William Dalby's word of caution towards the end of his article was urgently needed; just as members of the Stock Exchange are commonly supposed not to be able to see beyond the next account day, and some ophthalmic surgeons appear to regard a pair of spectacles as necessary for every patient who consults them, so many who dabble in nose, throat, or ear diseases have "adenoids on the brain."

I am, Sirs, yours faithfully,

S. JOHNSON TAYLOR, M.B., C.M. Edin.

Prince of Wales-road, Norwich, Nov. 30th, 1895.

CHLOROFORM IN TEETH EXTRACTION.

To the Editors of THE LANCET.

SIRS,—As there seems to be some difference of opinion on the matter, I should be glad if I might have the benefit of your opinion on the question as to whether or not it is legitimate to give chloroform in teeth extraction *under any circumstances*. I am told by some of my medical brethren that of recent years it is generally held not to be so, and as I am sometimes asked to administer chloroform for neighbouring dentists in cases where a number of teeth have to be extracted, I am naturally anxious to know whether I am justified or not.

I am, Sirs, yours faithfully,

Nov. 28th, 1895. J. B. CROZIER.

*** It is generally held that chloroform should not be given for dental operations, as the mortality under that anæsthetic is peculiarly high in that particular procedure. When, however, it is imperative that a clearance of a number of teeth or roots should be made a medical man is justified in giving chloroform. In such cases the patient should be kept lying flat on the back, should be freed from all tight clothing, and the same precautions adopted as though a major operation was to be performed. To give

Digitized by Google

chloroform to a casual patient sitting in a dentist's chair is not only most inexpedient but is highly dangerous.—ED. L.

"THE DIAGNOSIS OF TONSILLITIS."

To the Editors of THE LANCET.

SIRS,—Under the above heading, with reference to certain "cases in the parish of Fulham very like diphtheria in its early stage," Dr. Robert Lee states: "We have reasons for knowing that, although the Klebs-Löffler microbes may be present, this disease is not diphtheria." It would be conducive to a much clearer understanding if Dr. Lee would tell us what those reasons may be.

I am, Sirs, yours truly,

ARTHUR H. W. CLEMOW, M.D. Edin.

Earl's-court-road, Kensington, Dec. 3rd, 1895.

THE CASE OF DR. WIGHT.

To the Editors of THE LANCET.

SIRS,—The jury have found Dr. Wight guilty of the offence with which he was charged; but, after all, a jury composed of laymen must, even with the assistance of the evidence of medical experts, have great difficulty in coming to a just conclusion. They, no doubt, do their best in such cases, and no doubt they did their best in this case to master the questions submitted to them. Still, there are medical aspects of the question which they must find it almost impossible to appreciate. For example, rupture of the uterus in its most complete form may occur in the course of the operation of version, no matter how carefully performed, and no matter whether the operator merely be one of whom the ordinary degree of skill may be expected, or whether he be one of special skill and experience in the performance of obstetric operations. The same is true as regards cases in which the forceps is used. No doubt such an accident is of great rarity if care and skill be employed; nevertheless, in justice to Dr. Wight, it ought to have been clearly understood that such an accident may happen even in the presence of the highest skill and of the greatest experience. Further than that, in very rare cases rupture of the uterus may occur, not only apart from any operative interference, but apart from any known indication for operative interference. I have in mind such a case. The patient had had two children naturally before and was again in labour. There was no contraction of the pelvis, she had only been in labour some two hours, and the second stage of labour was well advanced, the os uteri being fully dilated, and everything apparently progressing easily and satisfactorily. Suddenly the patient became collapsed; she was then delivered easily with the forceps, but she died in about a quarter of an hour. The child was not unusually large. Post-mortem examination showed that a spontaneous partial rupture of the uterus had occurred under the peritoneum, with extravasation of blood rather low on the posterior wall; the peritoneal coat had then given way over the extravasated blood, and the patient had bled freely into the peritoneum, and so died of hæmorrhage. Had the forceps been used here *before* the collapse set in it might easily have been suggested that the fatal accident was due to the unskilful use of the instrument. The case was, in fact, an example of one of those unavoidable accidents that no amount of skill, so far as our present knowledge goes, can foresee or prevent. The possibility that Dr. Wight's patient may have died through the occurrence of an unfortunate accident in a category similar to that of the case briefly alluded to appears by no means improbable, and, at all events, he seems entitled to the benefit of the doubt, which it is almost impossible to satisfactorily eliminate.

I am, Sirs, yours faithfully,

M.D.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.—We are asked to state that, owing to want of room, the honorary secretaries are unable to issue any more tickets for the concert and distribution of prizes of the Volunteer Ambulance School of Instruction, which will take place at Crosby Hall to-day (Saturday).

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1227.*)

UNITY AND PEACE AT YORK: A DEFENCE OF THE FRIENDLY SOCIETIES' DISPENSARIES.

YORK is the first town I have visited where I have found a grievance and heard no complaints. The medical profession is absolutely united. The club medical officers hold a honoured position in the Medical Society. There is no complaint against them; all work harmoniously together. The profession looks upon the friendly societies' dispensary with no unfriendly feeling, and the general impression is that everything is for the best, if not in the best of possible worlds, at least in York, which is evidently, so far as professional interests are concerned, the best of possible towns. Not a little of its very exceptional contentment is due to the early organisation of the profession. The record carefully kept says that on Feb. 16th, 1832, a meeting of medical men was held in the house of Dr. Goldie in York. Dr. Wake was in the chair, and it was then decided to issue a circular invite "physicians and members of the Association of Surgeons Apothecaries resident in York" to form a medical society. The first meeting was held on the following March 3rd, and then the York Medical Society was formally constituted. From the very first the society displayed great activity. It held meetings at the dispensary on every alternate Saturday evening during the session. This continued till 1859, when a special room was rented in Minster street. The meetings were held there until the year 1874, and during the following three years in the board room of the York County Hospital. After this the society removed to a more central part of the city, and finally in 1890, a permanent library and meeting room was rented and furnished at Low Ousegate. The objects of this society are "the advancement and diffusion of medical knowledge." The membership is limited to duly qualified medical practitioners. The subscription is one guinea per annum for town members residing within three miles of the General Post Office, and half that sum for county members residing beyond this distance. A single payment of £5 5*s.* constitutes a life membership. The society holds every year twelve ordinary meetings during the session, which begins in October. The reading room is open from 10 A.M. to 10 P.M., and a sum is annually voted for the purchase of books and instruments. The members may borrow and use these instruments but are fined if the instruments are detained beyond a reasonable time or are not returned clean and in good condition. All the practitioners at York have joined this association. Now in the constitution of this society there are two features which have a practical bearing on the question of the clubs. From the very first, not only have the club physicians been admitted, but a special point has been made of gaining their adhesion. More than this, Mr. Bryson, the principal medical officer of the friendly societies' dispensary, has been elected a member of the council of the York Medical Society. Secondly, it will be noted that the society holds frequent meetings; thus the medical men are kept well in touch, and are therefore more likely to act loyally towards each other. Differences which are so often due to a want of mutual understanding may thus be explained away before they have time to reach an acute stage.

Both Dr. James Ramsay, the president, and Dr. Richard Turner, the secretary of the society, assured me that the medical officers in the service of the friendly societies were most honourable men, against whom there was no sort of complaint, and with whom they had frequent consultations. Little or no difficulty had arisen with regard to infectious cases and the notification of such cases. The club medical men had, in all circumstances, supported the York Medical Society. Dr. Ramsay, on his side, always refused to attend members of the friendly societies unless in consultation, in order to show club patients that they could not do just as they liked. If people join a club, then they must adhere to the medical officer of the club and not call in a private practitioner to make up for any shortcoming that may arise in the club method of treatment. Dr. Ramsay, however, far from feeling any resentment against these clubs, thought that the medical profession had

Digitized by Google

by overcharging, themselves favoured the formation of such institutions. He had known cases where bills for about £15 had been presented to servant girls whose annual wage barely amounted to that sum. Then a bill of perhaps £30 would be presented to the head of a family whose income might not exceed £200. Dr. Turner, when speaking on the same subject, remarked that there were very few members of the friendly societies who could afford to pay properly for medical attendance. Many families who belonged to the friendly societies could, on an occasional emergency, pay in the course of a year £2 or £3 for medical attendance. but if there was any serious illness the charge for medical attendance would amount to from £5 to £10, and this they really could not pay. The York friendly societies' dispensary is maintaining three medical men who are, taking all in all, as well off as if they had the same class of people on their books as private patients. The argument, I take it, stands thus: there are a number of families who could and would, without involving themselves in financial difficulties, pay £2 or £3; but if they are charged £5 to £10 the probabilities are that they will pay nothing at all. Is it not better that such families should pay some 8*s.* to 12*s.* per annum to a friendly society? Thus some sort of payment is ensured for medical attendance, the club medical officer is certain of his income, and the general practitioner is relieved of a large class of patients who constantly disturb him and require his services, but who never pay. Both the president and secretary of the York Medical Society do not believe that there is any strong feeling in York against the friendly societies' dispensary, and they are not troubled by commercial medical aid companies. Still they do not doubt that serious grievances exist elsewhere, and, if the profession take action in a national sense, the York Medical Society will, in all probability, not be wanting in the spirit of solidarity that should unite medical men throughout the country. It will, however, be necessary to discriminate between the abuse of contract work and the action of these friendly societies, which in their way are excellent institutions.

On calling at the friendly societies' dispensary I found Mr. Bryson, the chief medical officer, equally satisfied with things in general. His income was safe. It was sufficient for him to live in comfort, to bring up his family, and to have some enjoyment in life. He was allowed an occasional holiday, was not overworked, and had extra assistance during the influenza epidemic. He did not believe the dispensary was greatly abused by rich members. He was very strict in giving equality of treatment, and, by making rich men sit down among the poor patients and await their turn, a sort of wage limit was established. A man in a good business would lose too much time and prestige if he came to the dispensary. He thought that, of the new members admitted, there were hardly any who earned more than 25*s.* a week; but they sometimes rose to better circumstances in later years and still remained members of the society. These members who had improved their position in life sometimes preferred to keep to the medical officer of the club who had attended them in their less prosperous days.

Subsequently I had a lengthy and extremely interesting interview with Mr. John Brown, who is not only the secretary of the dispensary—the York Friendly Societies' Medical Association as it is called—but the general secretary of the Friendly Societies' Medical Alliance. Mr. Brown, as secretary of this alliance, is a sort of connecting link between all the friendly societies of Great Britain, and can, therefore, speak with great authority on the subjects at issue. Speaking in the first place of the local dispensary at York, Mr. Brown very clearly set forth why it was that this institution rested on a sound financial basis. He protested that it was a great injustice to take up a current balance-sheet of a society and forthwith pronounce judgment. The accounts of a current year could only be estimated at their real value and significance when taken in relation to the past history of the organisation. Thus, before investigating the last balance-sheet of the York dispensary it was first necessary to understand how that institution had been constituted. Eighteen years ago the members of the friendly societies at York determined to open a dispensary of their own. The first step taken was to make a levy of 1*s.* per member, which was called an entrance fee. In the course of four months they had collected £217. With this sum in hand they were able to hire a house at £40 rent and furnish it with the requisites for a dispensary. As they were able to pay cash they secured the best discount in the purchase of drugs, &c., obtainable in the market. Not content with this, they organised a grand bazaar, and the result was so good that they finally realised a total sum of £450. Having this capital in hand, the promoters of the dispensary were able to borrow at a low rate of interest some £575 more, and then to purchase a house for their dispensary. Thus at the present time, instead of paying £40 rent, they have larger and better premises and pay only £19 interest for the money they have borrowed. Then, again, one must take into consideration the shilling entrance fees, which at first were very numerous—£38 17*s.* in 1878, £33 4*s.* in 1879, and £30 2*s.* and £24 7*s.* the two following years. Since then the maximum has been £19 19*s.* in 1891, and the minimum £14 in 1892. All these sums represent the capital invested in the dispensary. Mr. Brown insisted on these figures at great length. He had heard talk of the "blood money" wrung out of the services of medical men, but he thought that if the accounts were more carefully examined it would be found that the fat profits which were supposed to have been sweated out of the labour of medical officers were in reality the fruits of patient economy or careful management, and the accumulation of small subscriptions paid by the members of the friendly societies. Thus, the present value of the premises, &c., at York was set down at £1620; and for this they had borrowed £575, which cost them £19 a year interest. Surely it was not too much to ask new members joining to pay 1*s.* as their share or contribution to this property or towards the original disbursements. This 1*s.* entrance fee could not be considered as a part of the sum paid for medical attendance. On the other hand, it was easy to see that the creation of such property was entirely to the advantage of the medical officers. The fact that at York they had ready money so as to buy their drugs in the very best and cheapest market, and that they only paid £19 interest instead of £40 rent, left more money in hand to pay the medical officers a good salary, to be more lavish in cab fares or in obtaining extra medical aid in times of epidemic. At York no committee-men were paid except the secretary and the treasurer, the former putting in a hundred nights' work in the course of the year. Mr. Brown believed that where friendly societies seemed, by their balance-sheets, to be making a profit out of the medical profession, if the details were examined it would be found that they were really creating a reserve fund, or so improving the property, the house, &c., as would, in the long run, tend to the realisation of economy. Such saving would be to the advantage of the medical man; for the society is then placed in a position to treat their medical officers better and give them greater security in the tenure of their office and for the payment of their services. At York the salaries of the medical officers were increased because there was a balance, but this year the society will probably not make ends meet. Therefore, with a fluctuating income and the prospect of an occasional epidemic it is only common prudence to carry over a balance from year to year. Thus, in 1894 a balance was brought forward of £197, and in 1895 the balance brought forward was £276. The salaries paid to the three medical officers amounted to £616 5*s.*, and the sum of £11 17*s.* 6*d.* was paid for a locum-tenent. The total receipts for the year were £1549 17*s.* 4*d.*, the expenditure £1470 6*s.* 3*d.*, leaving a balance of£ 79 11*s.* 1*d.* The £628 2*s.* 6*d.* paid to the medical men represent in round numbers 3¼*d.* per visit or consultation given during the course of the year. As this is net benefit and does not include drugs, the pay here is better than in many other places. The subscriptions also are higher. They used to be 3*s.* for men, and this has now been increased to 3*s.* 4*d.*; but the society understands—and this is not appreciated in many other places—that it is the women who require the most medical attendance; therefore, young women above eighteen years and married women have to pay 4*s.* 8*d.* Children, however, are admitted at the very low fee of 1*s.* 4*d.* per annum.

In answer to all these explanations I protested that no one disputed the great benefit of insurance against sickness, if only a wage limit could be established and if medical men were not overworked and underpaid. Mr. Brown, however, saw no practical means of establishing a wage limit, and did not believe in its necessity. He challenged the statement that medical men worked for less than the remuneration to which they were properly entitled. He was curious to know who was going to establish a wage limit for practitioners. What was the market value of a medical man's services? Was it not just whatever he was able to get? It seemed to him as if the medical

Digitized by Google

profession was a close and closed trades-union something like the guilds, crafts, and mysteries of the Middle Ages. But was it not better for the medical profession that a man should be made to pay into a benefit society rather than that he should go to a hospital? At all the workshops of York men might be seen sitting side by side earning the same wages—say 20*s.* to 30*s.* a week. The one joins a friendly society; the other, when ill, begs for an infirmary ticket. Which of the two best helps to maintain the medical profession—the man who pays 3*s.* 4*d.* a year for medical attendance or the man who pays nothing at all? But, it is said, there are well-to-do men in the friendly societies who ought to pay more than 3*s.* 4*d.* This is true, but when they joined they were poor men, and if they have remained in the society when better off it is very frequently because they have taken a deep interest in the movement. Being men of sufficient intelligence to rise in the world they are just the sort of men who would work hard for the society. In such organisations account must be taken of past hard and unpaid work, and it would be a great mistake to imagine that the present prosperity dropped ready-made from heaven. A society naturally likes to have some members in better circumstances, particularly as they are for the most part old comrades who have risen from the ranks. The societies are particularly desirous of electing a rich man as treasurer, it being safer, as it is neither wise nor right to tempt a very poor man with large sums of money. As for the trading classes as a body joining these friendly societies, Mr. Brown thought the modern tendency was in the opposite direction. The insurance companies had made so much progress that middle-class men and tradesmen insured their lives in these companies. The middle-class tradesmen no longer insured their lives in friendly societies or joined burial clubs, and therefore they likewise did not insure for medical aid. Indeed, anyone who could insure his life for £100 or more went to one of the great insurance companies, and was thus carried away from the friendly societies and the movement they represented. Therefore Mr. Brown concluded that the friendly societies' medical associations were likely to become more and more *bonâ-fide* working-class organisations. The middle-class element was becoming weaker instead of stronger; and the necessity of establishing a wage limit was not more and more urgent, but was disappearing.

For my part, reviewing all these arguments brought forward by Mr. Brown, I cannot help thinking that he was treating a national question as if the very exceptional condition of things which distinguishes the town of York in this matter from all the other towns I have visited prevailed everywhere. He did not seem to realise how the middle-class element abused the friendly societies' dispensaries at Lincoln. There the dispensaries are managed by middle-class men who have organised special privileges for the middle classes, although these wealthy tradesmen do not pay more than their poorer colleagues, the working men. Mr. Brown, on the contrary, assured me that at York, out of eighteen committee-men, there were only two that were not workmen. This makes all the difference. I feel convinced, from the numerous conversations I have had on the subject, that the great majority of the medical profession are animated with the sincerest sympathy for *bonâ-fide* working-class institutions. Nor is this sympathy merely a vague sentiment. It is practically manifested by medical advice willingly given for little or no remuneration to those who are really unable to pay the usual fees. But a feeling of justifiable resentment is equally manifest against those tradesmen and others who join working-class institutions so as to obtain medical aid at working-class rates of payment.

York, Nov. 28th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday and Sunday Fund.

THE twenty-sixth annual meeting of the subscribers to the above Fund was held on the 21st ult. The amount received this year was £345 more than in 1894, £266 of this being on account of the Saturday Fund. The total was £8200 12*s.* 8*d.*, the Sunday collections yielding £4125 17*s.* 8*d.* and those on the Saturday amounting to £4074 15*s.*; the greater part of the latter is given by the working people themselves. An auxiliary society of working men has been formed to assist the committee with collections from workshops, warehouses and other places of business. With the greatly increased organisation which is being brought about it is expected the receipts from the Saturday collections will be considerably increased. The chairman said that Manchester was much behind Liverpool, Birmingham, and other large towns in the amount collected. The working men were, however, now bestirring themselves in the matter, and it had been decided to give them a voice on the committee of management. At a meeting of the committee since the annual meeting a recommendation from the Workmen's Auxiliary to the Red Cross Society—to change the Hospital Sunday from February to the third Saturday after Easter—was adopted. An alteration in the date of the Hospital Sunday from February to a later month was considered, but was thought inadvisable to make any change at present.

Lifeboat Saturday.

This movement, originated by a merchant of this city in aid of the National Lifeboat Institution, has in the short time of four years spread widely. Last year a total of £21,000 was received from various parts of the country, while the average amount remitted from Manchester during the four years has been £4000 a year. There is an active Ladies' Auxiliary here, and an interesting ceremony took place on the 21st ult. in the town hall, as Princess Louise had consented to receive from the Lady Presidents purses containing the collections made this year. Lord Derby, who took part in the proceedings, said it was evident that the people had awoke to the responsibility entailed by Manchester having become a seaport. Before its connection with the sea more than one lifeboat had been subscribed for by Manchester people; now he believed there were not more than ten.

Cancer Pavilion and Home.

This charity, situated in Stanley-grove, is in connexion with, will be, with the Owens College Hospital when the new institution has become an accomplished fact. It was founded in 1892, contains about twenty beds, and its honorary staff are chiefly connected with the infirmary or college. At the annual meeting the other day it was stated that there was a deficit, as is usual with hospitals, of £204 10*s.* 9*d.*, due partly to painting &c. and some additional furnishing. "It is hoped, however, that the amount may be made good by the help of friends, and that the income of the hospital may in future fairly meet the expenditure." During the year ending Sept. 30th 147 cases were under treatment. Of the 108 new cases, 71 were inhabitants of Manchester and the immediate neighbourhood. The youngest patient was eight and the oldest seventy-five, the average age being forty-nine. During the year the hospital had provided a permanent home for 21 patients who could not be properly treated at home owing to the grave character of their ailment. Pay patients are received, and if this is ever justifiable it must surely be in the case of sufferers from cancer.

Manchester and Salford Sanitary Association.

At a meeting of the committee on Wednesday last it was announced that Professor D. J. Leech had accepted the office of chairman of the committee, vacated by Dr. Simpson, recently removed from Manchester, and the latter gentleman was appointed one of the vice-presidents. With regard to the milk-supply, it was decided to request the health authorities to have inspections of certain farms made, with particular reference to certain sanitary requirements. The position of the sewage disposal question in Manchester was considered, and adjourned pending information expected to be brought forward at the next meeting. On the question of the further provision of improved dwellings it was decided to submit a scheme to the Unhealthy Dwellings Sub-committee of the City Council, which intended to provide for well-paid artisans not obliged to live in the centre of the city separate dwellings with garden plots. The houses now occupied by this class would afford greatly improved accommodation for the tenants of cottages that ought to be condemned. The draft of a memorial to the Home Secretary was adopted praying that the flashing point of illuminating oils imported to this country may be raised from 73° to 100° F. And it was [illegible] stables be instructed when lamps [illegible] to prevent as far as possible [illegible] the cause of the accidents.

Digitized by Google

that poisoning accidents from carbolic acid were too few to make any attempt to schedule the poison likely to be successful. This scarcely tallies with the general belief, and it would be interesting to know how many more people must be poisoned before the Sanitary Association will move in the matter.

Manchester Institution for Diseases of the Ear.

The fortieth annual meeting of the above institution was held on the 22nd ult. The report said that during the year the number of attendances had been 7857, or an average of 30 per working day, and the number of new patients had been 1638. It was decided a short time ago to provide a few beds for in-patients. Sixty cases had been treated during the year, and a large number of operations successfully performed that could not have been undertaken without this provision. The extent to which the in-patient department had been utilised confirmed what had long been felt—namely, the desirability of removing the institution "to premises where the inmates, when convalescent, might have the benefit of purer air and more cheerful surroundings." This, however, cannot be till the means are forthcoming, and without special effort there must be a long period of waiting. The balance-sheet showed that the deficit of £6 with which the year began had now increased to £38. The difficulty of obtaining the funds necessary for the efficient maintenance of our hospitals has been felt for so long that it is scarcely surprising to see that the "question of income had long weighed heavily on the governing body." It appears that the fee of 4*d.* has been "experimentally" charged to out-patients, but was discontinued at the end of August, "each patient now being asked to contribute according to his or her means," with, so far, a financial advantage. "It was with great regret that the committee recorded the loss sustained by the death of Professor Williamson, one of the founders and a highly valued friend of the institution." Sir William Houldsworth, the chairman, in moving the adoption of the report, mentioned as a pleasing fact that the patients had contributed £198 17*s.* out of a total income of £529. The honorary secretary said "the patients hailed from all the surrounding counties and from North Wales," that the total number of subscribers from this large area was 147, "and sixteen of these were coöperative societies representing numbers of working men, who showed through their governing bodies their appreciation of the institution," so that the subscribers were about 1 in 10,000 in the district. This is unfortunately only typical of what happens with most of our charities—they are supported by the few, while the many are quite willing to make use of them.

Hospital for Incurables.

The twenty-fourth annual meeting was held on Thursday last. The report stated that the institution had just closed another year of usefulness and prosperity. The annual subscriptions had not fallen off, which in these days was satisfactory, and amounted to £2032, as against £2025 last year. Donations and legacies had brought the receipts to £8975 11*s.* 4*d.*, but there was an adverse balance of £1436 8*s.* 11*d.*, due chiefly to the cost of repairs at Mauldeth, and to the damage at Walmersley from the great storm last winter. On Oct. 31st there were 106 patients in the homes—22 males and 46 females at Mauldeth, and at Walmersley 38 females. In addition to these homes there is a dispensary at Ardwick Green where "those suffering from chronic diseases, and suffering from periodical, and oftentimes lengthened, attacks were able to obtain skilled medical advice and medicine without the trouble and annoyance of recommends." It must not be supposed from this that "recommends" are required everywhere else. It is intended, when the funds will allow, to grant "out-pensions," but at present that cannot be done.

Fatal Street Accident.

A somewhat extraordinary accident happened on Saturday evening. As Dr. Crean was driving along a street in Broughton the coachman felt something "go wrong" and pulled up. Dr. Crean got out and found a boy, who had apparently been riding at the back of the carriage, with his head fast in the springs. He was immediately released and taken to the hospital, but died before reaching it. It is supposed that he had been riding on the axle and slipped, so getting his head fast in the springs.

Dec. 2nd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

"Charity begins at Home."

UNDER the chairmanship of the Lord Bishop of the Diocese the annual meeting of the Newcastle Diocesan Branch of the Society for the Propagation of the Gospel was held on Nov. 26th in Newcastle. Two colonial bishops addressed the meeting. The Bishop of Riverina said: "There are 20,000 aborigines in North Queensland. We had taken their country from them; introduced all our own vices, which were killing them off." The Bishop of Zululand said: "We had taught the Zulus vices of which they knew absolutely nothing before." Both asked for men and money for the purpose of spreading among the Australians and Africans the religion professed by a people whose advent had had the disastrous results mentioned by the bishops. Our presence has exterminated the natives of Van Diemen's Land, and is exterminating the Australians and New Zealanders, notwithstanding all the efforts of the Society for the Propagation of the Gospel. On Nov. 27th the Rev. Canon Pennyfather, D.D., chairman of the Newcastle School Board, speaking at a meeting of the Fabian Society on child life in Newcastle, said: "The population of the city was about 207,000, and of this number nearly 1000 children were being brought up in industrial schools. The great cause of their being there was the low idea that men and women had of their parental responsibilities." On the eve of the opening of a bazaar in Newcastle for the National Society for the Prevention of Cruelty to Children, the Marchioness of Londonderry writes: "In eleven years no less than 130,000 children have been saved from unnecessary suffering, heartless neglect, and in not a few cases from a cruel death by the society." However much it may be incumbent upon us to do what we can to mitigate the evils arising from our presence in Africa and Australia, we certainly have a duty no less imperative at home. If the society could succeed in propagating the Gospel at home, is it not just possible that we might introduce fewer of our vices among people innocent of them? There would then be less need to send them men and money to counteract the evil of our presence.

The Only Cure for Distress.

This is, according to the *Newcastle Daily Chronicle*, the limitation of the population. The supply of labour exceeds the demand for it. What is the natural remedy? Restriction of the output. A man should live within his means, and has no right to introduce into the world more children than he can provide for. This is the argument employed by the writer of a most outspoken leading article recently published by the *Chronicle*. It is a sign of the times, and a very significant one, that such a leading article should appear in such a paper. It will undoubtedly have its effect. What view will the medical profession take of this open advocacy of Malthusian doctrine?

The Sub-Warden of the University of Durham.

Archdeacon Watkins has been appointed Sub-Dean of Durham University, but though the Dean is Warden of the University, the Sub-Dean is not necessarily the Sub-Warden. If when the office of Sub-Warden becomes vacant a layman should be appointed, a member of one of the Newcastle colleges, great satisfaction would be given. It is very generally felt that a further infusion of the lay element into the Senate would have a most salutary influence upon the future of the University, which is undoubtedly making rapid strides in the north of England.

Dec. 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Proposed Temporary Hospital required for Edinburgh.

Reference has been made previously to the fact that the Edinburgh corporation wishes to erect a temporary hospital on ground belonging to them, but lying within the boundaries of the burgh of Leith. The ground is regarded as very suitable for the purpose, but the Leith Dean of Guild Court and the Leith corporation continue to strenuously oppose it. The proposal has received the approval of the Local Government Board, but technical obstacles are found to block the

Digitized by Google

way and to prevent the erection of the hospital. On Monday last the Dean of Guild Court, presided over by the Provost, appointed that day fortnight for the debate on the question. The action of the Leith authorities will probably give a considerable impulse to the scheme for the amalgamation of the burgh with Edinburgh, and people begin to see the necessity of this from a public health standpoint.

Edinburgh Royal Infirmary.

At the meeting of managers this week a report was submitted regarding a fatality which recently occurred in the Royal Infirmary. A patient in one of the top wards jumped out of a window and received such injuries that she died soon afterwards. No blame was attributable to any of the officials. An application was also made to the managers from the Scottish Branch of the Soldiers' and Sailors' Families' Association asking facilities for the training of wives and daughters of soldiers and sailors in hospital work. The matter was remitted to the superintendent and the lady superintendent for report.

Hall of Residence for Women Medical Students in Edinburgh.

A movement has been started by a number of ladies in Edinburgh to provide a hall of residence for women medical students. A similar scheme has been in operation for years for male students, and has proved such a success that building has been added to building to accommodate an increasing number of applicants. A similar scheme in connexion with the Free Church College in Edinburgh has also been working for some time quite satisfactorily both financially and otherwise. A furnished house has been placed at the disposal of the ladies' committee free of rent for a year with a view of giving the scheme a start. Such a hall of residence would be of great value to women medical students, and if properly managed would doubtless become popular, and it is important to know from the experience of similar places for male students that they can be made to pay.

The Oyster Scare after Stirling Ball.

Mention has already been made of a number of cases of typhoid fever, several of which have been fatal, which followed a ball held at Stirling some weeks ago, and that suspicion had been thrown upon the oysters eaten. A Government inquiry into the matter has been instituted, and the opinion gains ground that the oysters were probably not to blame. Meanwhile the scare has greatly affected the consumption of oysters.

The Glasgow Crematorium.

The new crematorium built for the Scottish Burial Reform and Cremation Society in the grounds of the Western Necropolis was formally opened on the 27th ult. A short religious service was conducted by the Rev. Donald Macleod, D.D., and addresses were delivered by the Rev. John Hunter, D.D., Sir Charles Cameron, and Sir Henry Littlejohn. Amongst those attending were a large number of medical men, including Dr. Bruce Goff (the President of the Faculty of Physicians and Surgeons) and Dr. A. K. Chalmers (medical officer of health). The cost of the crematorium and chapel has been £2700.

Glasgow Western Infirmary.

The annual meeting of the qualified contributors to the infirmary took place on the 28th ult., Sir Jas. Bell, Lord Provost, presiding. The report drew attention to the decision of the managers to erect three new operating-rooms fully equipped to meet the demands of modern surgery at an estimated expense of £10,000. Plans for these have now been prepared after a visit, on behalf of the managers, of Dr. Mackintosh, medical superintendent, and Mr. Burnet, architect, to the principal Continental operating theatres. It was intimated that Lord Overtoun had generously given a donation of £3500 to build and equip one of the three new theatres. Another handsome gift which the managers acknowledge is the sum of £10,000 presented by Sir William Hozier for the purpose of founding an endowment fund for the Lady Hozier Convalescent Home at Lanark, which is in connexion with the Western Infirmary, and the house and grounds of which were presented to the infirmary by Sir William Hozier a few years since. The financial statement shows the cost of each bed fully occupied during the year to have been £55 7*s.* 8*d.* and the average cost per patient treated £4 15*s.* 6*d.*

Glasgow Maternity Hospital.

At the annual meeting of this institution on the 26th ult. Professor Murdoch Cameron in his medical report stated that the number of cases attended during the year had risen to 2721 and that 112 students had been in attendance. In referring to the resources of the hospital Professor Cameron drew attention to the fact that the number of in-patients had more than doubled within the past twelve years, and urged that immediate steps should be taken to enlarge the hospital and to establish a gynæcological department and dispensary. It was intimated on behalf of the directors that this recommendation had been favourably considered, and an appeal was made for funds to enable the directors to carry it into action. The increase in the number of students and young graduates attending the service of the hospital rendered more especially the introduction of women students necessitated a readjustment and extension of the present accommodation arrangements absolutely necessary.

Glasgow Medical Mission.

The annual report states that during the past year the number of consultations held at the dispensaries by the medical officers had been nearly 43,000, whilst nearly 10,000 visits had been made by the district nurses. The severe weather of last winter put a great strain on the resources of the mission, and a deficit of £582 is reported.

Accident Hospital for Wishaw.

At a meeting presided over by Lord Belhaven on Nov. 1st it was decided to erect a local hospital, at a cost of £1,[illegible] for the immediate treatment of men injured by the accidents so frequently occurring in the iron-works and coal-pits. The movement has resulted from the manifest risk to which patients seriously injured are subjected by a journey of fifteen miles to reach a Glasgow hospital, even though the journey is accomplished in an ambulance van.

Death of Dr. G. R. Mather of Glasgow.

The death of Dr. G. R. Mather, which happened on the 29th ult., took place under peculiarly distressing circumstances. As a Fellow of the Faculty he attended the annual dinner of the Faculty of Physicians and Surgeons of Glasgow and had just completed an enthusiastic reply to the toast "The Navy, Army, and Reserve Forces," when he suddenly became unconscious. He was promptly removed to a neighbouring room, but the measures taken to restore him proved unavailing. The funeral on the 3rd inst. was attended by the President and other officials of the Faculty and a large number of the Fellows. Dr. Mather was in his fifty-sixth year. He was a well-known practitioner in Glasgow and an enthusiastic patron of Scottish art. A year or two ago he published a volume entitled "The Lives of Two Great Scotsmen, William and John Hunter."

Presentation to Sir Charles Cameron, M.D. Dub.

The numerous friends and admirers of Sir Charles Cameron in the west of Scotland have, as a means of expressing their kindly feelings towards him, presented him with his portrait, the presentation being made on behalf of the subscribers by the Lord Provost of Glasgow. Sir Charles Cameron has represented Glasgow in Parliament for the long period of twenty-one years, but he was amongst the unsuccessful candidates at the last general election. A memorial in his honour is to be erected in a prominent situation in the city.

Dec. 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Rotunda Hospital.

THE "Thomas Plunket Cairns Wing" of the Rotunda Hospital was formally opened last week by her Excellency the Countess Cadogan in the presence of his Grace the Archbishop of Dublin and a large assemblage. His Excellency the Lord Lieutenant occupied the chair and alluded in his interesting speech to a committee of the House of Lords of which he was a member some years ago and which had for its object an investigation into the management and circumstances of the various London hospitals. After remarking that there was some reason to doubt the need for some of the smaller and special hospitals of which there were so many in London, his Excellency said: "But there are three classes of hospitals which to my mind at least are proved by the evidence before us as being very valuable in their nature and important in their maintenance. In the first place there are hospitals for women, a

the second place hospitals for children, and in the third place hospitals for treating diseases of the eye. These are the three classes of special hospitals the necessity for which, in my humble opinion, has been amply proved before us. We have in London no hospital for women of anything like the importance and size of this one." His Excellency would, I think, have been accurate in stating that neither in London nor in Europe is there any institution for the treatment of women of greater size or importance than the present Rotunda Hospital of Dublin.

Trinity College, Dublin.

The election of a parliamentary representative for Trinity College is causing great interest and excitement among the friends of the candidates, Mr. Lecky and Mr. Wright. The students have from the first taken a most lively and active interest in the proceedings—the medical undergraduates being as usual in the van. The demonstrations have not been confined within the College precincts, but have been frequently evident in the streets in the shape of marching regiments of good-humoured but very noisy young men cheering for whichever candidate they happened to favour.

Annual Dinner of the Ulster Medical Society.

The annual dinner of the Ulster Medical Society was held in the Grand Central Hotel, Belfast, on Nov. 28th. The President, Professor Sinclair, F.R.C.S. Eng., occupied the chair, and there was a very large attendance, including the Lord Mayor of Belfast (Sir W. M'Cammond) and the President of Queen's College (Rev. Dr. Hamilton), both of whom were invited guests. The following were the toasts: "The Queen and other Members of the Royal Family," proposed by the President; "The Lord Lieutenant and Prosperity to Ireland," proposed by Dr. W. A. McKeown and responded to by Dr. Henry Bingham; "The City and Corporation of Belfast," proposed by Mr. Fagan, to which the Lord Mayor and Councillor Henry O'Neill, M.D., replied; "The Queen's College and Belfast Medical School," proposed by Brigade-Surgeon McFarland and responded to by the President of Queen's College, Belfast, Dr. Walton Browne, and Professor Whitla; "The North of Ireland Branch of the British Medical Association," proposed by Dr. Kevin and responded to by the secretary of the branch; "The President of the Ulster Medical Society," proposed by Dr. Dempsey. The President having replied to this, he concluded by proposing "The Secretary of the Society," to which that gentleman responded. During the evening a capital musical programme was contributed by Mr. Mackenzie, Dr. Lindsay, Dr. McCaw, Dr. McKisack, Dr. R. C. McCullagh, and Dr. Leslie. The evening passed off very successfully.

Belfast Medical Students' Association.

A very largely attended meeting of the members of this society was held in one of the class-rooms of Queen's College on Nov. 29th; the President of Queen's College and several of the College professors and of the medical men in Belfast were present. The business of the evening was to hear the opening address of the new president of the association, Dr. Magowan, who gave a most interesting account of the origin, objects, and present aims of the society. The meeting was subsequently addressed by the President of Queen's College (Rev. Dr. Hamilton), Professor Byers, and Professor Sinclair. This association, the object of which is to promote the interests of the Belfast medical students as regards their professional training, is at present in a most vigorous condition and is sure to be of the greatest benefit in binding together the students of the Belfast Medical School.

Belfast Royal Hospital.

At a special meeting of the governors and board of management of the Royal Hospital held on Dec. 2nd Dr. R. Strafford Smith was appointed physician in place of the late Dr. Ross, and Dr. Calwell was elected, by a large majority, assistant physician in the vacancy created by Dr. Smith's promotion.

Health of Belfast.

The report presented to the city corporation on Dec. 2nd showed the health of the city of Belfast to be in a most unsatisfactory condition. During the previous four weeks a large number of cases of zymotic diseases were reported—viz., scarlet fever, 118 cases; measles, 35 cases; and typhoid fever, 30 cases. In this period there were 689 births and 532 deaths in Belfast; 84 deaths were from zymotic diseases, 60 from phthisis, and 178 from other respiratory diseases. In the corresponding period of last year the deaths from zymotic diseases were 60, those from phthisis 57, and those from other respiratory affections 110. During the four weeks embraced in this report 145 children under one year of age died, and 84 persons at or above sixty years of age, while in the corresponding period of last year the numbers were 104 and 81 respectively. The annual death-rate from all causes was 26·3, that for children under one year old 6·8, and that for those of ten years and upwards 3·9 per 1000 of the population. It will be thus seen that the deaths from zymotic diseases are very numerous, as are also those from chest diseases, and contrast very unfavourably with those of the corresponding period of last year, especially in the matter of diseases of the chest. We have at present an epidemic of scarlet fever and measles, and there have been a great many cases of typhoid fever.

A Clever Impostor in one of the Cork Hospitals.

A series of impositions has been practised in Cork by a French Canadian, a recent inmate of one of the general hospitals. He exhibited well-marked symptoms of hystero-epilepsy. He had hysterical hemiplegia and also the hysterogenic spots. Touching the latter produced well-marked spasms, which seemed to be very distressing to the patient. He expressed his strong conviction that the end was approaching, and he asked to have a solicitor sent for to draw up his will. The legal gentleman duly prepared the document, and the invalid soon found an opportunity for darkly hinting that in return for their kindness one of the house surgeons and one of the nurses had been remembered. Even swindlers have learned that "gratitude is a lively sense of favours to come." He pointed to a package neatly tied up and sealed, which he stated contained valuable securities, and requested the American Consul to see that it was carefully locked in a safe. It was so important that his will should be properly drawn that he sent for a second solicitor, and as it was all foreign money he had he requested one of the legal gentlemen to furnish him with a temporary loan in coin of the realm. Soon afterwards he left the hospital, and the sealed packet was examined. It was found to contain, not securities, but two copies of an illustrated newspaper. The police exhibit a decided interest in his previous history, and in medical circles the question is asked whether an impostor would be likely to know all about the various phases of hystero-epilepsy.

The Battle of the Clubs at Cork.

I mentioned some time ago that the Cork medical men proposed to form a club to be managed entirely by themselves. A committee has been appointed to formulate a scheme, and they have already made an important report. Amongst other things they recommend that the club should supply, not alone medical attendance, but that it should also provide sick pay and the ordinary benefits such as are available in connexion with the older clubs. In that way it is hoped a very large number of members from the recalcitrant clubs would be induced to join. One of the rules adopted by the profession at the commencement of the fight was that no medical man should form a new club till the year 1896. That rule was made in the interest of the men who had resigned their clubs so that they could get them back intact, and a movement is now on foot with a view to extend the limit of time with regard to the rule.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Trials of Country Medical Practitioners in France.

THE English parish medical officer is wont to deem himself—and not unreasonably so—the worst-used individual in existence. A stipend that a labourer would spurn, a mass of work that the same labourer would never consent to perform, unjust criticism on the part of guardians who have no conception of the dignity appertaining to our calling—these and a thousand and one other miseries would suffice to break the heart and sap the courage of a member of any other profession. This state of things is not, however, peculiar to the British Isles, unless the experiences of Dr. Boyron of Amagne are exceptional. This gentleman had the misfortune to be a club medical officer, and the mayor treated him accordingly much as he would treat a

Digitized by Google

gamekeeper. Dr. Boyron was the medical officer of a village Société de Secours Mutuels, and he found that, encouraged by the peasant-mayor, his club patients acquired the habit of treating him in a very cavalier fashion. He mentioned the matter to the mayor, who seemed to enjoy the joke immensely. The medical man thereupon resigned. The combative mayor, however, maintained that a club medical officer had no right to resign, and even had the assurance to contest (unsuccessfully) the legality of the resignation at headquarters. One day a station-master sent an urgent message for Dr. Boyron, who, on his arrival, found that the railway official had sent for him, not to ask his advice, but to tell him that he was being treated by a neighbouring priest, whose prescriptions he was requested to countersign, so that the company could be charged with the furnishing of the drugs. Listen to yet another story. A young medical man settles in a commune whose paupers he attended for (*horresco referens*) 50 fr. (£2) per annum. One night, soon after his arrival at this Eldorado, he received an urgent summons to visit a patient who lived at a distance of six kilometres from the village. On reaching the cottage—it was then 11 P.M.—he found the doors closed and lights extinguished. In reply to his knocks the door was opened by a sturdy peasant, who laughingly informed him that there was no illness in the house, but that his wife had wished to see if, when anyone was ill, he would come if sent for! The unfortunate medico—since dead from overwork, and probably under-feeding—remarked, "I could have felled him to the ground." Added to these annoyances, others of political origin are quite common in rural France. Our Gallic brethren meddle a good deal in politics, and as their tendencies are generally towards radicalism they have often *maille à partir avec le curé*. Altogether I should say that the British country medical practitioner has the best of it.

Professor Lannelongue.

The *fauteuil* in the Medical and Surgical Section of the Académie des Sciences, rendered vacant by the death of Professor Verneuil, has been filled by the election of M. Lannelongue, Professor of Surgical Pathology at the Faculty of Medicine and Surgeon to the Hôpital Trousseau (Children's Hospital). Professor Lannelongue will be known to your readers as the originator of the operation of craniectomy for the relief of premature union of suture resulting in idiocy. His closest competitor for the above-named honour was M. Ollier (Lyons) of periosteal fame, who, out of 60 votes, obtained 22, as against 36 for the successful candidate.

Illegibly signed Prescriptions.

My British *confrères* will probably know that French practitioners sign their prescriptions with their full surname generally preceded by the word Dr. This is compulsory, for Clause 32 of the Law passed on the 21st Germinal, Year XI. of the Republic, forbids pharmacists to dispense prescriptions unless they are thus signed. Unfortunately, signatures, especially of French physicians, are illegible, and pharmacists run, in such a contingency, the risk of prosecution if they furnish the medicament. Sometimes, however, the layman who presents the prescription has himself signed it—and signed it badly purposely. Such a case was judged by the Tribunal Correctionnel of Paris on the 16th ult. Here the pharmacist, who had accepted this scrawly signature and duly prepared the mixture, was found guilty and condemned to pay a fine.

Dec. 3rd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

A Question of Classification.

THIS is the day of Saint Andrew, whose intervention the Roman faithful invoke against death by apoplexy, though what connects that apostle and martyr with cerebral hæmorrhage I have never been able to make out. It cannot have been the suddenness of his exit from this life, for the Breviary tells us he lived for two days suspended on the cross. Nor can it have been the nature of his crucifixion, which was not like St. Peter's, with head towards the ground, pointing to that intra-cranial congestion which is the immediate cause of apoplexy. He was crucified on a decussating cross with head erect. Account for the connexion how one may, the fact remains, as votive offerings in the Sant' Andrea della Valle, for instance, can testify, that St. Andrew is the putative averter of apoplexy, and is invoked with special frequency and fervour in Rome, where death from that cause is traditionally common. Of late years, however, the medical statistician has refused to classify apoplexy what is popularly set down as the result of that lesion. A man suddenly loses consciousness, falls to the ground, and after a few convulsive movements is picked up dead, and "apoplessia fulminante" used to be accepted by professional authority as the cause of death. A more accurate etiology, however, excludes many such cases from the apoplectic category, and assigns them to syncope from cardiac lesion, or to embolism, or to one or other of the causes which pathology has established and confirmed by post-mortem examination. Your countryman, the late Dr. Aitken, for many years an able and esteemed practitioner among the English-speaking colony in Rome, was the first, I believe, to expose the error of classifying "apoplessia fulminante" what the physical signs clearly showed to be a form of syncope, due, for instance, to atheromatous heart or to aortic lesion. And, indeed, his work as corrective to the traditional classification might have been uncalled-for had his Italian colleagues fully mastered and followed up the great treatise of Lancisi, body-physician to Pope Clement XI., the treatise, to wit, entitled "De Subitaneis Mortibus," and even yet worthy of perusal, not only for its acute observation and sound reasoning, but for its limpid, fluent, medical Latinity. So St. Andrew, if taxed with failure to avert all cases of apoplexy, might fairly plead that many of these were outside his province and require for prevention the addition of a new protective saint in the Calendar.

Cremation.

This is indeed "a burning question" in Italy. In the Rivista Italia the return to the incineration of the dead was proposed and practised before any other European nationality more than dally with it—the Abbate Piattoli, Gorini, Coletti, Brunetti, Polli, and Clericetti being a few of the names associated with the first years of the movement. Keller of Milan led the way to its actual adoption, and after vindicating its propriety in his lifetime he bequeathed his body after death to the Società di Cremazione of Milan, to be reduced to ashes, and also left a considerable sum to establish a crematorium for the purpose. This was in 1876, and the contagion of his example spread to Switzerland, to France, to Germany, to Austria-Hungary, and to Great Britain, where a crematorium was erected at Woking. But Italy was the motherland of the movement and has maintained the lead in developing it; and (besides Milan) Lodi, Turin, Rome, Brescia, Cremona, Varese, Venice, Leghorn, Spezia, Padua, Novara, Modena, Florence, Naples, Palermo, Mantua, Como, Bologna, and other cities have either a crematorium of their own or are in process of constructing one. The latest is that of Turin, a magnificent structure, to which not only the local Società di Cremazione has contributed, but also, with an enlightenment desiderated elsewhere, the municipality. A provisional crematorium had been in use in the sub-Alpine capital since June 17th, 1888, but its insufficiency for the growing demands on it had become a public inconvenience. So this new and greatly extended one has taken its place, and will, when all the "colombaretti" are finished, accommodate no fewer than 2370 of these, not counting the two niches in the entrance hall and in the adjacent "edicole" or tabernacles. The apparatus of the crematorium is on the Gorini system, but with modifications suggested by other European crematoria which will reduce the duration of the process to one hour with a yield of white ashes weighing about three kilogrammes. The movement in which this great adjunct to sanitation has culminated is, in Turin as elsewhere, essentially a middle-class movement inspired, *inter alia*, by hygienic enlightenment and a wise recognition of the fact that where an ordinary cemetery could contain a million of dead, an ordinary crematorium can accommodate from ten to fifteen millions. As I have indicated, the aristocracy in Italy, as in other countries, discountenance cremation, and here in Rome we have in the great cemetery of the Campo Verano as many as 591 corpses yet awaiting definitive sepulture, provisionally lying, that is to say, in the quadriporticus that surrounds the cemetery as well as in the "locali di deposito" (depositing places). Allowed to remain in these *locali* after payment of certain inconsiderable fees, the unburied population of the cemetery has become so numerous as to compel the municipality to [illegible]

Digitized by Google

penalties, on its final inhumation. The abuses thus sought to be done away with are obvious, not the least being the infraction of hygienic law. The adoption by Rome of the system now practised in Turin and throughout Upper Italy would make such action of our municipality unnecessary.

The Rector of Bologna University.

A distinguished contributor to THE LANCET, Professor Augusto Murri, whose monograph "On Experimental Craniotomy and the Diagnosis of Cerebral Abscess"[1] is one of the events of the *annus medicus* now closing, has just been elected—by 38 votes against 14 for Ciamician, Professor of Chemistry, and 9 for Brizio, Professor of Archæology—Rector of the University of Bologna, where he holds the chair of Clinical Medicine. There is, indeed, some doubt as to whether he will accept the post, but in spite of the internal difficulties now agitating that seat of learning—difficulties which make administrative responsibility undesirable—it is hoped he will accede to the wishes of the majority—senatus and graduates alike.

Nov. 30th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Public Health in Hungary in 1894.

A REPORT which has just been presented to Parliament by the Government of Hungary does not give a very gratifying view of the state of public health in that country. There are still 11,105 villages without any medical man, a thing which is not surprising, because numerous local authorities refuse to pay fixed salaries to medical practitioners, and not many men can reconcile themselves to a dull country life and an income hardly exceeding £60 a year. In the larger towns there is one medical man for an average of 988 inhabitants, but in Budapest there is one for every 545 inhabitants. In 1894 there were 166,224 cases of zymotic disease with a mortality of 2·2 per cent., against 124,562 cases with a mortality of 2·7 per cent. in 1893. Of diphtheria there were 46,706 cases with 22,205 deaths in 1894, against 49,233 cases with 34,183 deaths in 1893, and of enteric fever 7646 cases with 2231 deaths in 1894, against 4895 cases with 1780 deaths in 1893. There were also 4896 cases of measles, 2218 cases of dysentery with 500 deaths, 1402 cases of puerperal fever with 833 deaths, 416 cases of cholera with 230 deaths, and 2365 deaths from influenza. The total number of deaths amounted to 453,094. Of trachoma 24,228 cases were registered in 1894, against 25,284 in 1893. There were 4280 medical men, 7981 midwives, and 2092 pharmaceutists; in 1893 the number of medical men was 4153. There were 334 hospitals, and to these there were admitted 166,524 patients, of whom 6·7 per cent. died.

"Thyreo-antitoxin."

At the last meeting of the Vienna Medical Society Dr. Fränkl described his attempts to isolate the active substance in thyroid preparations, for which purpose he made cold or warm extracts of dried thyroid glands of the sheep, and separated the albuminous matter by adding acetic acid. In order to determine whether the curative properties were possessed by the precipitate which contained albumin, or by the filtrate, the former was given to two well-nourished men, who during ten days consumed daily the precipitate of seven glands without showing any loss of body-weight, whereas Dr. Fränkl, who himself drank the filtered fluid, sustained a daily decrease of 300 grammes (about 10·5 ounces), and found that his pulse-rate was increased. From this experiment he inferred that the filtrate contains the efficacious material. By inspissating it and by separating the lime he obtained a substance which he calls "thyreo-antitoxin," and to which the formula $C_6H_{11}N_3O_5$ may be assigned. It is inodorous and tasteless, and is therefore recommended for use.

The Pathogenesis of Tertiary Syphilis.

In a paper on Tertiary Syphilis read by Professor Neumann at a meeting of the Vienna Medical College on Dec. 2nd he said that cell infiltrations dating from the early stage, when mechanically or chemically irritated, give rise to proliferation and consequent tertiary symptoms in the skin, the mucous membranes, the bones, and internal organs. He referred also to the necessity for observing the idiosyncrasy of the patient, the general state of his health, and the existence of concurrent diseases, such as phthisis, malaria, and diabetes. Among intelligent communities, with the exception of large towns, there is but a trifling amount of tertiary forms, whereas in countries where ignorance and superstition prevail syphilis shows a malignancy resembling that displayed at the time of its first outbreak. By means of observations on 1048 cases he proved the influence of the treatment of the primary symptoms on the occurrence of tertiary forms. Syphilis, he concluded, is to be treated symptomatically and not preventively, nor by Fournier's chronic intermittent method In the primary stage local treatment is to be adopted, and extirpation may be resorted to in some cases. Preventive treatment may be applied in the form of inunction in cases of œdema of the prepuce and phimosis or when the affection is localised in the urethra. General treatment is to be commenced when the skin eruption appears, and there are cases in which it should be carried out even in the absence of any symptoms, as when marriage is contemplated, or in pregnancy, or in the case of a man whose wife has often miscarried. According to his experience tertiary symptoms are observed in only 10 per cent. of the cases of syphilis treated in this way.

Enteric Fever in Vienna.

According to the report of the Sanitary Department there were 62 cases of enteric fever in Vienna at the end of last month. This is the highest rate which has been registered during the present year, the cases of enteric fever numbering 33 in January, 14 in February, 7 in March, 12 in April, 24 in May, 17 in June, 27 in July, 32 in August, and 51 in September. But these 62 cases include only 51 inhabitants of Vienna, the other 11 cases having occurred in travellers arriving from Venice and Silesia.

The New Director of the Vienna Lunatic Asylum.

Dr. Adalbert Tilkowsky has been appointed director of the Vienna Lunatic Asylum, in succession to the late Dr. Gauster. He was born in Hungary in 1842, and in 1874 was elected assistant in this asylum, where he remained till 1884, when he was transferred to Klosterneuburg; and in 1891 he became director of the lunatic asylum at Ybbs. Dr. Tilkowsky is one of the most eminent Austrian experts in lunacy and neuropathology. It was through his endeavours and recommendations that the Government ultimately submitted the Inebriates Bill to Parliament.

A New Test for Mercury in the Urine.

Dr. Yolles has published his new method of recognising mercury in the urine. For this purpose he recommends the use of granulated gold, which possesses in a higher degree than any other metal the faculty of forming an amalgam. To 100 c.c. of urine he adds 2 grammes of gold and from 1 to 3 c.c. of hydrochloric acid. On the addition of 2 or 3 c.c. of freshly prepared chloride of tin flocculi are precipitated, after which he boils and mixes the compound with from 30 to 50 c.c. of chloride of tin and boils for five minutes. After removing the supernatant fluid and washing the gold with distilled water he adds three or four drops of nitric acid, and again the same quantity of chloride of tin. If only 0·0002 gramme of mercury be present a turbidity or cloudiness is produced.

Cholera in Galicia.

The last report announces 19 cases of cholera and 14 deaths from the districts of Czortkow, Husiatyn, Taroslaw, Buczacz, Trembowla, and Kamionka, making a total of 351 cases with 234 deaths since the commencement of the outbreak.

Dec. 1st.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera News.

THE daily cholera bulletins come now from six districts, though it must be remembered that each district includes a certain number of villages and hamlets. The past week shows a total of 46 new entries into the ambulances, with 31 deaths in hospital and 25 deaths outside. This gives a total of new cases of 71, or 10 per day. It looks now as if the disease were completely subdued on the important canal running between Mansourah and Menzaleh, but several new

[1] THE LANCET, Jan. 5th, 12th, and 26th, and Feb. 2nd, 1895.

Digitized by Google

villages have been attacked on the Nile between Mansourah and Damietta; also there has been a case at Mansourah in the person of a native medical man's daughter. It appears that he was summoned to an infected village to perform a cholera necropsy, and in so doing he soiled his shirtsleeves. Disdaining the use of the disinfector in the town, he had his clothes washed at home, by this child among others. There have also been 2 cases in the town of Zagazig, one of which has already recovered.

Examination of Suspicious Cases.

A circular letter in three languages has been sent to all medical men informing them that the bacteriologists of the Egyptian Government are ready to examine, free of charge, all suspected material sent to them. Instructions are also given as to how discharges or soiled linen are to be despatched from a living patient, and how two portions of the ileum are to be forwarded after the necropsy of a fatal case. Extra assistants are now working in the two laboratories of Cairo and Alexandria, and to save time a considerable amount of the work is done by night.

Vaccination Statistics.

The figures for 1894 have just been published and show that there have been 336,605 births in Egypt during the year, only 1056 of which were among Europeans. The number of deaths was 194,256. No one knows the present population of this country. It is guessed at by various people as being something between seven millions and ten millions. If the lowest computation is taken it is found that there is a death-rate of 27·7 per 1000, but if there are now as many as eight millions the mortality is at once reduced to 24·2 per mille. It is a great pity that the Government does not yet see its way to arranging for a new census. The successful vaccinations of the year amount to 312,188, and the unsuccessful to 3548, some of those vaccinated having doubtless already had small-pox. The successful revaccinations were 3257. Since 1890 vaccination has been obligatory for Europeans as well as natives. The statistics of the first week of November show that there were 58 cases of small-pox with 4 deaths, and, moreover, that this disease was scattered over no less than four provinces of the Delta. Small-pox is therefore more widely spread than cholera.

British Troops in Cairo.

The Cairo garrison now consists of 3200 men, with a sick-rate as low as 5·5 per cent., and this includes only twelve cases of enteric fever. This disease is much less common this year than usual, and the general sick-rate is very low, because the army of occupation has lately consisted entirely of troops who have been a long time in Egypt. When a new regiment arrives the enteric fever rate is certain to go up. Ever since 1883, when 194 of the English soldiers were attacked by cholera and 142 died, it has been recognised that if the troops are to be moved at all they must be moved before cholera has actually appeared among them. Arrangements have been carefully made on paper for several cholera scares, but this is the first time that it has been deemed necessary to take any practical steps. Now the nucleus of a tent hospital has been made at Abbassiyeh, where the desert permits an unlimited stretch of fresh air. A health camp for 1000 men, with a field hospital, has been made beyond the Pyramids. At Helouan a similar health camp could be made, and the troops now at Abbassiyeh could be moved further afield into the desert, thus leaving in Cairo only the men actually necessary for military reasons. But none of this preparation will be made use of unless cholera should actually break out in Cairo itself. In the meantime an extra strict sanitary inspection has been made of all barracks and other buildings. It is greatly to be regretted that the Pasteur-Chamberland filter has not yet been granted for the use of English troops in Cairo. In this respect the army of occupation is several years behind the German Hospital, the Egyptian Government Hospital, the schools, hotels, and other large buildings in Cairo.

British Troops in Alexandria.

In Alexandria there are only 1100 men with a sick-rate to-day of 5·8 per cent., including three cases of enteric fever. There are only two companies now at Ras el Tin barracks, the bulk of the troops being established in new huts at Ramleh, near the old Mustapha Pasha barracks, which have been condemned and partly pulled down. The situation was good enough and the sea air was perfect, but it was found that the young soldiers of any new regiment suffered from a high rate of enteric and simple continued fevers. Many explanations for this have been proffered; it is not necessary to search for any mysterious cause; knows that in the early days of the British occupation partly from ignorance and partly from economy, the pools and conduits which honeycomb the Egyptian barracks were never filled up and, worse than were employed for several years as drains for sink laundry water. The Royal Engineers in 1882 contented themselves with closing all latrines superficially and plying a movable system of tubs for urine and fæces. army system which expects Royal Engineers to be sanitary engineers without giving them an adequate in this subject is responsible for much of the disease death among our troops in Egypt. I am glad to be able state that for the last year medical representations have ceeded in obtaining Pasteur-Chamberland filters barracks and hospital in Alexandria. In the event Alexandria ever being threatened by cholera the troops be moved out to a camp at Abukeer and tent hospitals be established.

Sanitary Officers.

The only good thing which as yet cholera has done Egypt is that the Government has consented to increase European *personnel*. Dr. Rogers Pasha has obtained leave appoint another permanent English medical inspector also to create an Institute of Public Health, which is presided over by a bacteriologist. For this latter post said that Dr. Bittar, at present sanitary inspector Alexandria municipality, will be one of the candidates. Leave has also been granted to appoint a temporary English inspector for the ensuing twelve months. the present moment there are working in the city villages four English medical men, with four police officers, and forty-four native medical all additional to the usual strength. The expenditure course, met by a special cholera grant, and no difficulty have yet been raised by the financial authorities. Mansoura for instance, is being kept clean at the rate of £2 a though the whole budget for municipal expenses in times is only £6 daily. The sanitary department intention of at once providing permanent disinfectors some of the chief towns in the Delta, for at present only Cairo and Alexandria which possess them, and buying some portable disinfecting machines for work provinces. These will, of course, be of great use, not for cholera, but also for the annual small epidemics typhus fever, relapsing fever, small-pox, and measles.

The Tourist Season.

The hotels and tourist agencies are still confident visitors will not be afraid to come to Egypt, because no places already engaged on the Nile steamers and boats have been counter-ordered. Greece is still the country which has put Egypt into quarantine. imperial archdukes from Austria are on their way it is certain that they would not be allowed to come authorities in Egypt believed that there was any risk doing so.

Cairo, Nov. 27th.

Obituary.

PROFESSOR ANDREA VERGA.

MEDICO-PSYCHOLOGY has to lament the loss of one most able and original votaries by the death of Dr. Verga, for many years associated with the Ospedale Maggiore of Milan as professor of that subject. He was born Treviglio, of comparatively humble parents, on May 3rd 1811, and received his education, literary, philosophical and medical, at the University of Pavia. He was a favourite pupil of the celebrated Bartolomeo Panizza, Professor Anatomy in that school, and under his influence became his time, one of the profoundest physiologists, particularly in the department of neurology, south of the Alps. attention was early attracted to the phenomena of mental disease, and, shortly after his brilliant graduation as Doctor of Medicine, he became director of the Manicomio di San Celso in Milan. This he soon made conspicuous by the

success of his treatment in obscure cases, and in consequence was in 1848 promoted to the direction of the still greater Manicomio della Senavra. By this time his fame as a medico-psychologist was high and his capacity for administration not less so, in recognition of which he was made Director of the Ospedale Maggiore of Milan, one of the largest and, historically, one of the most celebrated institutions of its kind in Italy. To him it owes the foundation of a professorship in the doctrine of medico-psychology and of a clinical lectureship in connexion with the same, while its general efficiency, far in advance, in many important respects, of Italian hospitals attached to even greater schools, dates from his active association with its administration and work. Dr. Verga was not less busy with his pen than in his professorial and consultant capacity. He was the author of many important memoirs and monographs scattered through the Atti or transactions of medical congresses, while his great treatise, composed in elegant Latin, on "Hallucinations" received the prize of the Académie de Médecine of Paris, and his work on Leprosy was similarly honoured at the Congresso Scientifico of Naples. These and other emanations from his pen have been translated into most of the European languages, and in many cases preceded his election to learned bodies, particularly those of medicine, in the several Continental capitals. Probably no Italian physician was "Corresponding Fellow" of so great a number of such societies and associations. In the Peninsula itself his presence at national and provincial medical congresses was always welcome, and at that of the medico-psychological specialty, which he may be said to have founded, his intervention sufficed to maintain the discussions at a high level of scientific and clinical thoroughness. Besides this professional distinction he was a loyal friend of literature and fine art, his skill in Latin epigrams being not inferior to that of Cesare Cantù, his brilliant contemporary who predeceased him last spring. As President of the Lombard Institute of Science and Literature he raised that body to rare efficiency, but always refused, though often invited, to enter Parliament. He was, however, provincial and communal councillor, taking much interest in the sanitary duties of the post, and in recognition of his public as well as professional services he was made by King Victor Emmanuel senator of the kingdom in 1876. For some time past Dr. Verga had been suffering from gouty eczema, and was attended by his colleagues Dr. Rossi and Dr. Bertarelli, Professor of Dermatology in the Milan school. Quite lately an abscess of the lip had to be opened by Dr. Ritordi, and while this seemed to be doing well grave pleuritic symptoms supervened, which on Nov. 20th developed alarmingly. On the 21st he died, at a quarter to four in the afternoon, retaining his intelligence and serenity to the last. His tall, striking figure and kindly address will long be missed at medico-psychological congresses, Italian and foreign. But the mark he left on his specialty will perpetuate his name. He anticipated a great deal of what is most sound in the teaching of Lombroso, and his relegation of incorrigible crime to the class of moral imbecility has had an important bearing on the judicial procedure of his country. His insistence on the necessity of attaching a lunatic side to prisons and penitentiaries has fructified usefully in more than one centre of population. Again, in the literature of his subject, a selection from his numerous writings will have permanent value, in connexion with which the republication is contemplated of his lectures on Lazarettos and on the Functions of the Brain, lectures which always drew crowds to his class-room, not of students only, but of past masters in the profession.

HENRY LAWRENCE, M.R.C.S. ENG., L.R.C.P. EDIN.

MR. HENRY LAWRENCE, who died recently at Clifton, was a well-known and popular practitioner in Bristol, his father having been for several years chaplain to the prison there. Born in 1848, he became a Member of the Royal College of Surgeons of England in 1871, receiving part of his medical education at the Royal Infirmary, Bristol, and at the Middlesex Hospital. He became a Licentiate of the Royal College of Physicians of Edinbugh in 1874. The deceased gentleman was public vaccinator for Bristol, and was at one time surgeon accoucheur to the Bristol Dispensary. To the Bristol Lying-in Institution he acted as honorary surgeon. By his friends Mr. Lawrence was held in high esteem, and his death, which took place after a short illness, will be deeply felt by the public among whom he practised.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

So far from the business of the recent meeting of the Council being of an easy and formal character requiring only a short time for its disposal, the Council sat six days and had to come to decisions of unusual difficulty and importance. Some of these we have already noticed as disposed of by the Council in the two first days of the session. Throughout the session the absence of the initiative of the Medical Defence Union was felt. Had the full energy of this and the sister society—the London and Counties Medical Protection Society—been put forth on one or two matters which engaged the attention of the Council it is possible that different conclusions would have been reached. It is to be hoped that an understanding will be come to with these bodies that will encourage them to undertake the presentation of cases to the Council which affect either the honour or the interests of the profession. It is to be remembered that they are voluntary societies, doing much work that should be done, if not by the General Medical Council, then by the Public Prosecutor or the Registrar-General. To expect from such societies all the force and formalities of legal procedure is unreasonable. The wonder is that the work has been done with so much approach to legal precision without the power to enforce legal methods.

The report of the Examination Committee on the various reports of the inspector and visitors of examinations, and the series of recommendations arising out of them occupied a day, or a day and a half, of the Council's time. The discussion was a little too prolonged, and, indeed, led to the Council not being able to finish its business on Saturday. It cannot be said that any new principle for the guidance of the examining authorities was enunciated. The action of the committee led by Sir Dyce Duckworth was rather to emphasise points in the old set of recommendations. Mr. Teale has given notice of resolutions—to be found in our report of the proceedings—which aim at crying a halt in the immense burden of examinations which is now laid on the student's back, and at reducing the number of them. The time was not sufficient for the discussion of such an important suggestion. But the resolutions have been put on the minutes, and Mr. Teale, who speaks with great thoughtfulness and authority on such matters, has given notice that he means to go very fully into this subject at the next session of the Council.

A very noticeable feature of the proceedings was the report of the Public Health Committee, showing that in the chairman, Dr. Thorne Thorne, the Council has got a successor to Sir John Simon who has the same determination to hold high the standard of examinations for diplomas in sanitary science. It was in no abatement of this determination that the report gave a kindly and almost a humorous hint that there were practical limits to the subjects of examination, even of the "distinctively high" diplomates, and that they could not reasonably be asked far-fetched questions in physical science, as of the mass of Jupiter, the oscillation of the pendulum, or concerning the law as to admissibility to evidence of dying declarations, or in mental physiology, and the like. It is much to be regretted, as Dr. Thorne Thorne points out, that no less than fifteen registered bodies in the United Kingdom now confer registrable diplomas in the United Kingdom. It adds much to the difficulty and the expense of inspecting examinations when they are so numerous, and it must also tend to some competition downwards. We

Digitized by Google

cannot tell the exact number of successful candidates, but they can scarcely give more than two or three to each board. It is to be hoped that the licensing bodies which now act in conjunction only for ordinary diplomas will not continue to give separate diplomas in State Medicine.

The petition from the Apothecaries' Hall of Dublin for the appointment of surgical examiners, arising out of the fact that the Royal College of Surgeons in Ireland had terminated its conjoint arrangement with the Hall for giving a complete diploma, was reconsidered on Friday, the debate being postponed from Wednesday, Nov. 27th. It will be remembered that the Council reported this conjoint examination to the Privy Council as being insufficient. The reply of the Privy Council left the General Medical Council in a position of some embarrassment. It (the Privy Council) saw no reason to decide on the insufficiency of an examination which had practically ceased to exist. There was much division of opinion in the Council, some thinking the defects of the extinct Conjoint Board an opportunity and a justification for ending the Apothecaries' Hall, others arguing that it should have another chance under conditions prescribed by the General Medical Council. Irish opinion was much divided. In the end it was resolved to refuse to appoint surgical examiners. The hall is now in the position in which the Society of Apothecaries of London was placed by the refusal of the other bodies to form a conjoint board. Such a position in a corporate body always excites some pity and a feeling that the body has not had a fair chance. It remains to be seen whether the Hall will apply to the Privy Council and whether that body will order the General Medical Council to appoint examiners, or, failing this, will themselves appoint them. It is undeniable that the Hall has not the same claims that the sister body in London had. But according to Sir John Banks it fills a distinct place and meets a distinct want in Ireland.

The session of the Council which has just closed displayed the general desire of those representing the qualifying and educational bodies to be faithful to the recommendations of the Council and to the duty of holding high the standard of medical education. The penal and disciplinary powers of the Council are still undeveloped and undefined. It has resolved, however, to take one new step—as perhaps it might not have done if the Medical Defence Union were not holding aloof—viz., to prosecute a quack who trades on the lowest set of feelings and fears and who takes the title of "Dr." wherewith the more to impress the ignorant. This is a new function and one attaching more to the Public Prosecutor or the police. But let us hope that these authorities may be led by the Council's action to do their duty in the interest of public morality.

THURSDAY, NOV. 28th.

The winter sittings of the General Council of Medical Education and Registration were resumed at the Royal College of Physicians of London in Pall Mall East, Sir RICHARD QUAIN, the President, being in the chair.

New Recommendations for Examinations.

Sir DYCE DUCKWORTH, as chairman of the Examination Committee, submitted the following report:—

"Specific recommendations by the Examination Committee in regard to the results of visitation and inspection of the final examinations in medicine, surgery, and midwifery of all the licensing bodies:—

"1. That fixed intervals of time between the several examinations should be maintained, and that two years should intervene between the date of passing of the final examination in anatomy and physiology and that of admission to the final examination in medicine, surgery, and midwifery.

"2. That the extreme sub-division of examinations, and particularly of the final, as now permitted by some boards, should not be sanctioned.

"3. That questions in all the written examinations of the different bodies should be submitted to the whole of the examiners in each subject before they can be set at any examination.

"4. That candidates in all their examination work should be [illegible] supervised.

"5. That at least half an hour should be allowed for a candidate to answer each question in the papers on medicine, surgery, and midwifery.

"6. That no candidate should be orally examined in any subject or part of a subject, except in the presence of two examiners.

"7. That the clinical examinations in medicine and surgery should be conducted under the personal surveillance of two examiners, one of whom should always examine the candidate orally on each case although the adoption of this rule might necessitate in some instances additional clinical examiners.

"8. That there should always be an examination of secretions, as in testing urine, in clinical microscopy, and in prescription writing, and always an oral examination in both medicine and surgery, which should include the recognition of pathological specimens.

"9. That at every final examination there should be a practical examination in pathology, macroscopic and microscopic, unless this has been included in the examination immediately preceding the final examination.

"10. That the examination in midwifery, forensic medicine, and hygiene should be made as practical as possible.

"11. That whatever the system of marking may be, the percentage for a pass (50 per cent. in each division of a subject) should be uniform in all the boards, and in accordance with previous recommendations of the Council.

"(a) That the marks given on the written examination ought not, as is the case with some boards, to dominate those given at the subsequent clinical examinations.

"(b) That marks given in any part of an examination should be given on the merits of that part alone, and not be subject to future revision unless for the correction of a manifest error.

"(c) That the recommendation of the Council that knowledge of a subject should not be allowed to compensate for ignorance in another is not sufficiently regarded by some of the examining bodies.

"(12) That as the art of examining is only to be acquired by practice it is desirable that an examiner should be re-elected, where practicable, for at least five consecutive years, particularly for the final examinations."

He (Sir Dyce Duckworth) said that this series of recommendations had been drawn up with great care and consideration by the Examination Committee as the result of the large experience which had been gained by visitation and inspection of all the licensing boards in the kingdom during the last three years. It had been thought that recommendations in this form would be a great advantage to the various examining boards. He moved that the report be received and entered on the minutes.

Mr. BRYANT seconded the motion, which was adopted without further comment, and it was agreed that the Council should resolve into committee to discuss the recommendations in detail.

Sir DYCE DUCKWORTH formally moved, and Mr. [illegible] seconded, the adoption of Recommendation 1.

Mr. TEALE suggested that the Council should pause before adopting a proposal of this sort. The difficulties students had to face to get through the curriculum in five years were already very great, and he questioned whether the interval proposed in this recommendation would not increase these difficulties. Rejections at the final examinations were not decreasing but increasing. In 1861 the average percentage of rejections was 12·4; in 1876 the average had increased to 22·2 per cent., and in 1891 to 39·3 per cent. Their professional examinations were very uncertain, very unprecise, made up of a great deal of chance, and those who went up for them required no little preparation. It seemed to him that to keep them from the hospitals until they had got through their anatomy and physiology would not benefit them, and that the interval between the passing of the examination in anatomy and physiology and their admission to the final would rather keep them back.

Mr. BRYANT said that if the resolution was adopted it need not be that students should be excluded from clinical work until they had passed their anatomical examination. There were schools in which students were so excluded, but he did not believe in them. The resolution would give them with more time for preparation for the final examination, and in doing so he believed it was a wise step. He submitted that there was no tangible force in Mr. Teale's objection.

Dr. MACALISTER claimed to have had experience of the working of such a rule at Cambridge. After nearly twenty years' operation of it, it had been found to have no effect on the weak men, while it hampered the best men. Many men who went to Cambridge got much of their education elsewhere, and though they were ready to take the examination they could not avail themselves of that education until they had met the requirement of three years' study at Cambridge. This rule would therefore hamper men who were ready before the expiry of the interval it set up, and he rather doubted if it was wise on the part of the Council to put down a cast-iron rule of this kind. The matter seemed much more

Digitized by Google

that should be left to the bodies themselves. He was afraid he should not be able to support the resolution.

Sir WILLIAM TURNER said that from Mr. Bryant's speech the Council might infer that it was the practice at present for candidates to pass their anatomical examination at the end of the second year and then leave the full period of three years between the passing of that examination and the admission to the final. That was undoubtedly the case as regards the Conjoint Board system in London, but that was not the case in Scotland. The ordinances of the Scottish universities required that a man should not be allowed to go in for his anatomical and physiological examination until the end of the third year, the rest being taken for the more clinical and practical side of his work. Therefore the argument advanced to meet Mr. Teale's objection, while good enough for London, did not apply to Scotland. Were it made a hard-and-fast rule that there should be an interval between the passing of the anatomical and physiological examination and the date of the passing of the final it would be a hardship to many candidates. The final examination in anatomy and physiology was held a month or so before the expiry of the second year. If this resolution was passed and it went to Scotland the authorities in that country would have to treat the matter with some latitude. They could not treat it rigidly, for if they did so it would be penalising their candidates, and that would be unjust to them. If it was passed they must put their own interpretation upon the meaning of the term "two years." It was because he looked at the matter from that point of view that he offered no objection in committee to the resolution as it now stood.

Dr. MCVAIL was very sorry to hear Sir William Turner's remarks. He thought this was a resolution on which the Council would have been quite unanimous. He did not know any resolution that had come before the Council that was so entirely worthy of their confidence. It was the case that careless students left over the examination in anatomy until they were engaged with the more serious subjects. He had known of students who, in the final year of clinical medicine, had not passed either in anatomy or physiology, and were, in fact, still actually working away at "Quain's Anatomy" and "Kirke's Physiology." These men had either been careless or had not been able to pass their examinations. Was a man who had not at the end of three years passed the examination in anatomy fit to go on in the three great subjects of medicine, surgery, and midwifery? He held that he was unfit. He did not think there was any hardship in this resolution at all. He could hardly imagine the Council rejecting it or having any tenderness for men who could not comply with it. Any such deserved the hardship, if it were hardship, of being kept back. The keeping of them back was a protection to the public.

Sir WALTER FOSTER felt that the recommendation embodied an idea that had for a long time been in the mind of the Council. The great defect in this country for the last thirty years had been this, that they did not get their students into anything like a disciplined curriculum. They wanted to get their students classified—divided into those who were studying the scientific basis, and those who were engaged in the practical application of the scientific basis to the arts of medicine and surgery. But the question was whether that could be done through the regulations of the General Medical Council or through those of the licensing bodies themselves. He thought it might be done by the students being logically kept in these two classes. Some such classification as this resolution aimed at would weed out the worthless students. He believed that if they had this classification they would get a great stimulus towards discipline, and it was because the resolution aimed at more discipline that he supported it.

Mr. BRUDENELL CARTER regarded the remarks made by Dr. McVail and Sir Walter Foster as very clearly expressing what was on the mind of the committee in adopting this recommendation. He thought the committee's feeling was that at the period of time a student approached his clinical work he should go forward with unfettered mind and so should be able to devote to it the whole of his faculties. They did not contemplate that he should have before him an examination that he should already have passed. When the resolution was originally drawn the words "at least" appeared before "two years." These words "at least" had been inserted to meet such cases as that to which Sir William Turner had referred. On the general principle he (Mr. Carter) thought and hoped that there could be little doubt that the scientific basis and practical application marked two periods, and that as far as possible these two periods should be kept distinct.

Dr. LEECH remarked that it seemed to him the advantages of the resolution far outweighed its disadvantages. He did not think it would result in an addition to the number of rejections to which Mr. Teale had referred. It would induce men to work, for if they knew they had to pass certain examinations before entering upon clinical work they would study harder.

Dr. BATTY TUKE asked if the resolution meant to imply that men should apply for examination at the end of two years.

Mr. BRYANT replied that that was the custom, leaving the three other years for purely clinical work. It was in marked contrast with what went on in Edinburgh, where they gave three years to preparatory work and two years for the rest.

Dr. BATTY TUKE: Exactly. Then it implied, he went on to say, that each man must study anatomy and physiology in one year, which was an utter impossibility. When a first-year's man had to study biology, chemistry, and physics he could not do more, and this resolution would throw the study of the two institutes of medicine into the second year, and one year was wholly insufficient.

Mr. BRYANT explained that a hope was entertained that the first year's subjects would soon come to be looked upon as subjects to be taken before entering upon the medical course proper, and when that came to pass there would be more time for the study of anatomy and physiology, and surely two full years should be enough for the average student.

Dr. BATTY TUKE pointed out that he had been taking into view only the existing conditions.

Mr. BRYANT suggested that the conditions were more and more becoming what it was hoped they soon would become. To meet any difficulty felt, he was willing to see the resolution altered by putting the word "academic" before "years," and leaving out "midwifery." In regard to the latter, some of the boards were considering whether a man might not be admitted in midwifery twelve months after his passing the examination in anatomy and physiology.

Dr. LOMBE ATTHILL said his belief was that the students did not devote so much time to work in the five years' scheme as they did under the old system, and he therefore thought this resolution a step in the right direction. If, however, it made it imperative that anatomy and physiology were to be passed at the end of the two years, he should oppose it. As the course was one of five years, a man might pass in these subjects at the end of the third year, and yet pass in the five years. As to midwifery, he thought that was a subject that should be taken at the end of the course.

Mr. TEALE said the point the last speaker made was this: he asked for three years for anatomy and physiology; in doing so he asked for a six years' course.

Dr. ATTHILL: The final is to be taken at the end of five years. You mean that?

Mr. BRYANT: Yes.

Mr. TEALE: Is this the real final?

Mr. BRYANT: The final that gives the diploma. We might say "last," instead of "final," examination in anatomy and physiology.

Mr. WHEELHOUSE: The resolution says nothing about the curriculum, but only that a certain time must elapse as between examinations.

Dr. FRASER said that in Aberdeen until a student had passed in anatomy and physiology he remained a third year's student. That, he thought, was very desirable. The great curse to a student was that he went on while he was unfit for the work. Unsuitable men kept hanging on. The resolution would be a good thing for the teachers as well as the students and the parents of the latter. It was practically carrying out the scheme in operation in the north of Scotland.

Sir DYCE DUCKWORTH intimated that he was willing to word the resolution as follows: "That fixed intervals of time between the several examinations should be maintained, and that two academic years should intervene between the date of the passing of the last examination in anatomy and physiology and that of admission to the final examination in medicine, surgery, and midwifery."

Dr. BRUCE: Is this the final shape in which you propose to send the resolution to the bodies?

Sir DYCE DUCKWORTH: Yes, if it is adopted.

Dr. BRUCE: Then I think it requires a little more consideration. I do not think it would be possible to carry it out.

Dr. HERON WATSON pointed out that the only thing the

Digitized by Google

committee proposed was an alteration of the period at which the examinations should be taken up, and his firm belief was that if the rule were established it would exercise a wholesome effect upon the students. It would certainly influence them not to waste time and to endeavour to pass the requisite examinations within the prescribed time.

Dr. MACALISTER said it was clear they were agreed that students should have two clear years after physiology and anatomy were done with. If that was what they wanted they ought to say so. They should say that before any student was admitted to the final examination he should present evidence of at least two years' clinical study subsequently to the examination in physiology and anatomy. He moved to this effect.

Dr. BRUCE seconded the amendment.

On a division the recommendation as amended was carried by a majority, the amendment being supported by only 5 votes.

Sir DYCE DUCKWORTH moved the adoption of the second recommendation. He did not think any objection could be raised to this resolution. Passing examinations in instalments was exceedingly bad, and the Council had pronounced it very undesirable.

Mr. BRYANT seconded the resolution.

Dr. BATTY TUKE remarked that the only objection he had to the resolution was that it was not strong enough.

Dr. LEECH agreed to the resolution so far as regards the final examination, but not so far as intermediate subjects.

Dr. MACALISTER thought the word "extreme" weakened the resolution.

Mr. BRUDENELL CARTER was of the same opinion. He himself had suggested in committee that the word "extreme" should be left out.

Dr. CAMERON asked what "sub-division" meant.

Mr. BRYANT said that as regards the final examination in medicine, surgery, and midwifery, all the subjects at some universities were taken together. In the examinations of other bodies, however, the subjects were taken separately; this was what was meant by "sub-division." As to what was meant by "extreme sub-division," supposing a man went up for medicine and passed in the written part of the examination and not in the clinical, he must go up for the whole again. Some boards thought they got better results by allowing the pass rather than insisting on the subject being taken again.

Dr. BATTY TUKE: Then the recommendation is in favour of piecemeal examination?

Mr. BRYANT: No.

Dr. MCVAIL thought Dr. Tuke's view quite right. It seemed to him that the resolution gave powers to hold the examination in medicine at one time, in surgery at another, and in midwifery at another. He did not think the three subjects should be dissociated from each other. They should be passed at one time, and if a man did not pass in two he should be re-examined in these on going up again. He moved as an amendment: "That in the final examination the whole subject of medicine, surgery, and midwifery should be passed at the same time, and that failure in one of the subjects shall involve re-examination of the whole."

Dr. CAMERON seconded the amendment.

Dr. GAIRDNER could not go so far as the latter part of this amendment proposed. In Glasgow they had a rule under which a man who did not pass in one subject, but had a really good mark in the rest, was remitted for three months.

Dr. MCVAIL was willing to take the opinion of the Council on the first part of his proposal.

On a vote the amendment was rejected, and the committee's recommendation was adopted without amendment.

The third recommendation was adopted in this form—viz., "That in all the written examinations of the different bodies questions in each subject should be submitted to the whole of the examiners before they can be set at any examination."

Sir DYCE DUCKWORTH, moving the adoption of the fourth recommendation, explained that one or two instances came before the committee where there was laxity in the matter of supervision, and therefore he thought this recommendation desirable and necessary.

Dr. BRUCE took the view that it was not necessary, but the Council decided to adopt the recommendation.

A considerable amount of discussion took place with regard to the fifth recommendation.

Sir DYCE DUCKWORTH said that several cases came before the committee where the questions were such that they could not be answered in the allotted time.

Dr. WILLIAM MOORE expressed the view that half an hour was too short a period to allow.

Mr. BRUDENELL CARTER, speaking in defence of the recommendation, said it would have a twofold beneficial influence, because in the first place it would secure to the candidate sufficient time in which to do justice to his own knowledge of the subject, and in the second place it would tend to some extent to guide the examiner as to the character of the question that should be put.

Dr. BRUCE thought that the Council should have the courage to say that certain bodies did not set their papers properly, instead of sending down this general recommendation.

Dr. PETTIGREW said that the difficulty might be got over if they recommended that at least three hours be allotted to each candidate to answer the questions in the written examinations in medicine, surgery, and midwifery, and left the details to be worked out by the examining bodies.

Mr. BRYANT suggested that an average of half an hour might be adopted—that was to say, if there were six questions the candidate would be allowed three hours to answer them.

This suggestion was at once adopted by the Council and incorporated in the recommendation.

Recommendation 6 was adopted in the form proposed by the committee.

The seventh recommendation was put in this abbreviated form: "That the clinical examinations in medicine and surgery should be conducted under the personal surveillance of two examiners."

Dr. MCVAIL asked whether the committee had considered the question of holding clinical examinations only in hospitals. He wanted to know whether the system was to be allowed to continue by which a board brought two or three show cases—something very striking in the way of heart murmur or jaundice or skin eruption—and put these down in a row in a room and called that a clinical examination. In Scotland they would not so call it, because there were many cases that they examined on in the hospital ward which could not be brought to a waiting-room and diagnosed there. He objected to what he would describe as the "snap-shot" clinical examination, and he was glad to think there was nothing of the kind in Scotland.

Dr. ATTHILL: Nor in Ireland.

Dr. MCVAIL said he would be glad to hear something on this subject from Sir Dyce Duckworth, Mr. Bryant, and Mr. Brudenell Carter, who were all members of the Examination Committee.

The PRESIDENT ruled the discussion out of order on the present recommendation, telling Dr. McVail that if he wished he could bring up a proposal of his own when the recommendations of the committee were disposed of.

The recommendation in its abbreviated form was then agreed to.

As to the eighth recommendation,

Dr. HECTOR CAMERON asked what were the secretions that were required. He could understand that saliva could be got and possibly tears, but it would be difficult to get bile and other things. In its present form the recommendation did not give any idea of what was meant.

A Member: Sweat.

The recommendation was then put into this form: "That the final examination should include the examination of secretions, the testing of urine, chemical microscopy, and prescription writing; and there should always be an oral examination in both medicine and surgery which should include the recognition of pathological specimens."

The ninth recommendation was agreed to without discussion.

With regard to the tenth recommendation,

Dr. ATTHILL said that while he agreed with its principle he knew that the carrying of it out would be found impossible.

Sir DYCE DUCKWORTH said there was one examining body in the three kingdoms which carried out practical clinical midwifery. It was a solitary instance, and the committee quite recognised that most boards would have difficulty in carrying out an examination of that kind, but in the course of examining the report of the inspector and visitors the committee found that the examination in midwifery had been by no means practical in some instances, that no attempts had been made by the use of the phantom to get at practical questions. As to hygiene, it was possible that the Examination Committee had a little overstepped the actual

Digitized by Google

requirements. Since this matter was brought up the whole subject of public health had been transferred to another committee under the chairmanship of Dr. Thorne Thorne, and possibly it might be desirable to expunge hygiene and make the recommendation read "midwifery and forensic medicine."

Dr. BRUCE objected to hygiene being omitted, because he held that every medical practitioner should have an intimate knowledge of that subject and that his knowledge should be tested in the ordinary way.

Dr. THORNE THORNE took the view that it might with safety be omitted from the ordinary pass examination.

Dr. BRUCE persisted in his objection, but the Council agreed to the recommendation with hygiene omitted.

The preamble of the eleventh recommendation having been adopted, sub-head (*a*) was made to read: "That the marks obtainable in the written examination ought not, as in the case of some boards, to override those given at the oral or clinical examination," and sub-head (*b*) was adopted in the form proposed by the committee. Sub-head (*c*) was moved in this form: "That the former recommendation of the Council—that knowledge of one subject should not be allowed to compensate for ignorance in others—should be more carefully regarded by some of the examining bodies."

Dr. MCVAIL called upon the Council to specify the bodies. This was a charge, and it should be made open and specific as was demanded, in the interest both of the bodies and the public at large.

Sir WALTER FOSTER agreed with Dr. McVail. He had been following these proceedings closely, and the conclusion he had come to was that they were pursuing a wrong line. The best course for them would have been to take all these reports of the examiners, cull out all the specific charges of negligence or inefficiency with regard to the examinations, and, having done so, to pass directions that each body should be called to order for its omissions or neglect. If that had been done, then they would have avoided sending down many of these truisms to the bodies generally. These documents would make the Council the laughing-stock of half the bodies in the kingdom because they did not apply to them. They would be put into a position which did not reflect any great credit on the Council, or add to the dignity of its proceedings, or gain it any respect as an authoritative body upon medical education.

Sir DYCE DUCKWORTH differed from Sir Walter Foster and Dr. McVail. He thought it would have been most invidious if the Examination Committee had gibbeted each body, and preferred that each one should be left to fit the cap to its own head.

The sub-head was then agreed to, as was also the twelfth recommendation.

Dr. MCVAIL moved as a further recommendation: "That the clinical examinations in medicine and surgery should be held in hospitals wherever that may be possible." He compared the system adopted by the Conjoint Board in England with that in Scotland, and expressed his decided preference for the latter.

Mr. BRYANT said he was afraid Dr. McVail had never been present at an examination of the Conjoint Board, because he appeared to know nothing about it. The cases were not such typical cases as he described, there was no hurry, and the examination was just as perfect as any that could be carried on in a hospital. In the London hospitals, moreover, it would not be possible to carry on the examination fairly, nor would it be to the interests of the patients.

Dr. MCVAIL said his contention was that it was impossible to have a proper clinical examination of patients sitting in a waiting-room.

Sir DYCE DUCKWORTH replied that the patients were brought into a spacious, warm, and comfortable and well-ventilated chamber, where they received every attention, and said he felt certain that the governors of hospitals in London would object to students being brought into the wards from time to time for the purpose of clinical examination.

Mr. BRUDENELL CARTER expressed the view that it would be impossible to get in a hospital a better examination than that of the Conjoint Board. The cases were carefully selected, and every facility was given to the student for approaching and examining them.

The recommendation of Dr. McVail was carried by a majority, and the Council adjourned.

FRIDAY, NOV. 29TH.

The Council met, Sir RICHARD QUAIN in the chair.

Unregistered Dentists.

The PRESIDENT intimated that he had received a letter from the British Dental Assistants' Association asking the Council to receive a deputation with reference to a petition on the subject of the admission of certain dentists to the Dental Register. The deputation, he was told, was in attendance. The Council deliberated for a time *in camerâ* on the question of receiving the deputation, and thereafter the President informed the gentlemen that the Council, having already decided the question of the admission of non-registered dentists, and not being prepared to reopen it now, was unable to receive the deputation. The deputation accordingly withdrew.

The petition in question was in the following terms, viz.:

GENTLEMEN,—We, the undersigned dental assistants, beg respectfully to bring before your honourable board a grievance under which we suffer. Through a misunderstanding on our part at the time of the passing of the Dentists Act, 1878, we did not take the opportunity to apply for registration, as some of us were not out of our apprenticeship, and others, who were assistants at the time, were quite ignorant of the Act. Some of us noticed Section 37 of the Act in the year 1882, some in 1883, and some at a later date, and applied for registration, but were refused on account of being "too late." Since that time up to Dec. 5th, 1892, your honourable board have granted registration in about 400 cases (according to Dental Register, 1895); and we consider, as we applied before that date, the same privilege ought to be extended to us. We are all qualified according to Section 37 of the Act. We have been articled as pupils, and most of us have paid a premium to a qualified dental practitioner for the dental education we received, while some of us, who paid no premium, gave time in lieu of cash. Our articles expired before the first day of January, 1880. We have now been twenty, twenty-five, or more years in "dentistry"; we are all married and have families depending upon us, so that it is quite impossible for us now to turn to other callings. We therefore pray that your honourable board will take our precarious position into kind consideration, and extend the same privilege to us as your honourable board has been kind enough to extend to others. May it therefore please your honourable board to admit us as "registered dentists," and to authorise the Registrar to enter our names on the Dentists' Register upon payment of the usual registration fee.

The Apothecaries' Hall of Dublin.

The Council then proceeded to the consideration of the application of the Apothecaries' Hall of Dublin for the appointment by the Council of two examiners in surgery. The application was made owing to the Royal College of Surgeons in Ireland having withdrawn from the combination with the Apothecaries' Hall, and in virtue of the provisions of Section 5 of the Medical Act of 1886, which says that if a medical corporation represents to the General Medical Council that it is unable to enter into a combination for the purpose of holding qualifying examinations, and the Council are satisfied that the corporation has used its best endeavours to enter into a combination, and is unable to do so on reasonable terms, it shall be lawful for the Council from time to time, if they think fit, on the application of the corporation, to appoint any number of examiners to assist at the examinations.

Dr. CHARLES F. MOORE moved that the petition be granted. He explained that he had received letters from Dr. Haughton and Dr. Kidd, who were unable to attend this session of the Council, expressing the hope that the petition might be successful. Having done this Dr. Moore gave an account of the position and work of the Apothecaries' Hall, and assured the Council that if they granted the petition no pains would be spared to make the examinations thoroughly satisfactory in every respect and well up to the requirements of the Council.

Dr. PHILIPSON seconded the motion without making a speech.

Sir JOHN BANKS, speaking in support of the application, said that the apothecaries supplied a want in Ireland. They were needed by the poorer class of people, who were not able to pay the ordinary fees of physicians and surgeons, and he could assure the Council that they were a highly respectable and accomplished body of men. He was confident that if they were afforded the opportunity of going on they would do well in the future.

Dr. ATTHILL said that all along the Apothecaries' Hall had attributed their failure to the ill-will and persistent hostility of the Royal College of Physicians of Ireland. He could assure the Council that such ill-will and hostility did not exist. He and the other Fellows of the Royal College of Physicians of Ireland respected and esteemed the great majority if not the whole of the governors of the Apothecaries' Hall, but what they objected to was that

Digitized by Google

a body subordinated to them in certain important particulars should be made in all respects their equal and be made a qualifying body. Dr. Moore had said that there had been a systematic combination on the part of the Royal College of Physicians of Ireland to prevent their Fellows examining for the Apothecaries' Hall. That was not the case. He had a letter from one of their Fellows in which he stated that for two years he had been an examiner to the Conjoint Board without any Fellow of the College making any objection to his action and that afterwards he was appointed an examiner by the College itself. The fact was that the standard of the examination was lowered, and in course of time men refused to act as examiners. That was the true explanation of the difficulty. Dr. Atthill then went at length into the history of the Apothecaries' Hall, showing in what circumstances it was constituted and how it was subordinated in certain respects to the Royal College of Physicians of Ireland.

Sir PHILIP SMYLY said he had asked for instructions from his body (the Royal College of Surgeons in Ireland) as to this matter, and they decided to give him a free hand and no instructions. He therefore wished to speak, not as a representative of his College, but merely as a member of the Council. The question here was not the existence of this body, because it existed by Act of Parliament, but whether surgeons were to be given to it to complete the examinations, and he distinctly thought that they should be given. He asked that the Hall should be given a fair and honest trial as to what it could really do under fair conditions.

Dr. HERON WATSON intervened to say that the motion and the application on which it was founded hardly appeared to be consistent with the provisions of the Act. The section said that it should be the duty of the assistant examiners to secure at the examinations the standard of proficiency in medicine, surgery, and midwifery required by the Act, and how by appointing examiners in surgery were they to secure proficiency in medicine and midwifery? Instead of two examiners he fancied they would have to appoint an entire board of examiners.

Dr. MCVAIL thought the Hall should withdraw its present application and reapply in May, asking the Council to appoint such examiners under Section 5 of the Act as the Council might see fit in order to constitute the diploma of the Hall a qualifying diploma.

Mr. BRUDENELL CARTER pointed out that the Act only empowered the Council to appoint examiners to assist.

Dr. MACALISTER thought it a truly Hibernian method to appoint examiners in surgery for an examination which had been declared deficient in medicine. And, after all, the defects in the Hall were not confined to the examinations; they were found in the curriculum, in the advertisements, and in the programmes.

Sir WALTER FOSTER said he was sorry the corporate bodies in Dublin had not taken a somewhat more generous view of the difficulties of the Apothecaries' Hall. He thought the Hall had not been very fairly treated, and he appealed to the more generous instincts of the Council to come to its aid.

Dr. BATTY TUKE took the view that if this application were granted one of the great and important functions committed to this Council by Act of Parliament would fall into abeyance. They might remain as a council of registration, but it was very doubtful whether they could long continue as a council regulating medical education. For thirty-five years the Council had been trying all they could to raise the standard of medical education. They had done so by the application of sensible pressure—using the word sensible in both its senses. They had set up a standard of proficiency, and the standard must be protected. Why did the Royal College of Surgeons in Ireland leave this body?

Sir PHILIP SMYLY: We did so at the request of this Council.

Dr. BATTY TUKE thought the Council would put their own interpretation on the conduct of the Royal College of Surgeons in Ireland. When the Hall put the matter before the Privy Council it did not say *peccavi;* on the contrary, it said it had done right all through, and this body asked the General Medical Council to reconstitute and galvanise it again into existence. If the Council did so, they would stultify their action in the past and render themselves utterly useless in the future.

Dr. HERON WATSON, seconded by Dr. MCVAIL, moved:

"1. That the application of the Apothecaries' Hall in Ireland and the motion of Dr. Moore founded upon it are not in accordance with the provisions of the Medical Act, 1886, Section 5. 2. That the authorities of the Apothecaries' Hall be informed of this, with a view, should they think fit, to make a new application for the appointment of such examiners to assist at the examinations of that body in [illegible] surgery, and midwifery as shall secure at the said examinations maintenance of such standard of proficiency as is required under provisions of the Act, 1886, from candidates at such examinations."

The PRESIDENT said that the Apothecaries' Hall were anxious to get a distinct answer to their application, and thought they would be quite justified if this amendment passed in going to the Privy Council.

Dr. CHARLES MOORE said that the question of appointing examiners in medicine had been before the Hall and quite on the cards that they might so apply.

The PRESIDENT said he had a strong feeling that amendment was altogether wrong.

The vote was then taken, when 9 members voted for Dr. Heron Watson's amendment and 12 members against it. Seven members refrained from voting on either side.

The PRESIDENT said the original motion was lost.

Sir DYCE DUCKWORTH said that Dr. Tuke had placed question on a truly wide and impartial basis—for basis of this question. As chairman of the Examination Committee, for the last five years he had gone through all the reports relating to this qualifying body his mind was fully made up as to what he was going Left standing alone, helpless, and unable to carry work, they were asked to prop it up. If this Council to accede to that they would stultify all the work of three years, and would deserve to be, and would laughing-stock of the whole medical profession. Apothecaries' Hall of Dublin had had many chances and it had not availed itself of any of them. He believe it was able to make itself a satisfactory had had its day, and he thought it ought to die gracefully.

Dr. GLOVER reminded the Council that in the last years the Apothecaries' Hall of Dublin had not acted It should not get all the blame for inadequacy and ciency. The responsibility must rest on the Conjoint He for one thought the Apothecaries' Hall should chance, and in order that it should not be excluded list of qualifying bodies he proposed as an amendment "That the petition of the Apothecaries' Hall of Dublin granted on the condition that this Council appoint addition to examiners in surgery, examiners in cine and midwifery to act as assistant examiners under Section 5 of the Medical Act of 1886." hoped this amendment would bring the Council unanimous vote. Such a vote would have an effect. It would put this body on its mettle. examiners from this Council would practically be ("No, no," from Sir Dyce Duckworth), whose duty be to secure such proficiency as was required, and failed in securing that efficiency it would be their duty, and no doubt their action also, to report to the the unsatisfactoriness and insufficiency of the examination.

Dr. BRUCE seconded the amendment. He urged the proposal were accepted one result that would would be that the students who had a claim upon the Conjoint Board would, instead of hanging on to this go to the new body.

Dr. THORNE THORNE asked if this amendment was in order. The Council were asked officially to appoint examiners in surgery for the Apothecaries' Hall. The ment asked them to do something more. If they something more the body applying might not accept might resent it, and unless the Council had some document to show that it would be accepted, why they take the proposal into consideration at all?

Dr. CHARLES MOORE said he had a specially written authorising him to use his discretion at this Council regard to anything that might be proposed at it. the power to withdraw the proposal he himself had before the Council.

Sir WILLIAM TURNER thought the Council had a right know where it was at any particular moment. The before them a definite motion from Dr. Moore, which had been discussing all day long with amendments. the last moment they were told that that motion was the final application of the Apothecaries' Hall—they told that the representative of that Hall had plenary Why did not Dr. Moore tell them that at first?

The PRESIDENT: Mr. Muir Mackenzie advises me the amendment is quite in order.

Sir WILLIAM TURNER said that if they were to take

Digitized by Google

osal without anything like a proper application they
l not be complying with the Act. They had no appli-
n. They should have an application from Dr. Moore
rom the body he represented.

e PRESIDENT: The amendment proposes to grant
iners on condition.

. LEECH thought it would be very dangerous to proceed
is way. They should not vote in a hurry.

. MACALISTER was of opinion that it would be perfectly
petent for the Apothecaries' Hall to accept the examiners
urgery and to decline the others in medicine and mid-
ry.

r. MCVAIL asked to be allowed to suggest to Dr. Moore
withdraw his motion and allow the Hall to make applica-
under the Act. It was perfectly certain that that motion
t stood now would meet with a disastrous fate, as many
ld have to vote in an adverse sense who might be dis-
d to assist the Hall if an application from them for
miners in all the subjects were before the Council. He
not think the Council would be wise in accepting from
Moore the mere statement that he had plenary powers;
re ought to be a definite written application under the
. The Hall would not lose anything by getting time in
ich to make application.

Ir. BRYANT hoped the Council would keep to the point
ore them. They were asked to help the Hall. How could
y do it? The position taken up by Dr. Tuke and sup-
ted by Sir Dyce Duckworth was precisely the position he
r. Bryant) held himself. He certainly was at a loss to see
v the Council could so stultify themselves in a session in
ich they had agreed to inform the Lord President of the
vy Council that the opinion of the General Medical Council
to the standard of proficiency required by the Conjoint
ard of Ireland was based on the results, not of one inspec-
n only, but of four special inspections and visitations, and
t the remarks made in the communications from the
othecaries' Hall of Dublin and the Royal College of Sur-
ons in Ireland had been considered by the Council and
ey saw no reason to alter their opinion as to the standard
question. Were they now disposed to stultify that position
together and to say that it was not so bad after all? Even if
ey were to act on the amendment they would be making the
aminers the nominees of the General Medical Council, and
l over the kingdom it would be looked upon because of that
a very good board to go to. They had heard much about
e Apothecaries' Hall being utterly ruined if they did not
et their examiners. He did not see where the ruin came in.
hey only removed a growth that had sprung up since 1858,
efore which the Apothecaries' Hall was a mere medical
oard—a board that had never held a position equal to that of
e London Apothecaries' Hall. In all times since 1858 this
ublin Hall had been a failure. The Council would look
erfectly ridiculous in the eyes of the public as well as of
he profession if, after asserting so repeatedly that the board
as inefficient, they should think of propping it up, especi-
lly with examiners appointed by the Council.

Sir PHILIP SMYLY remarked that the Royal College of
Surgeons in Ireland had maintained that they had made a
good surgery examination. The managing committee had
o voice whatever in the selection of medical examiners.
If they had had any voice in the matter, then some respon-
sibility might lie upon them. He had been asked for the
reason that the College left the combination with the
Apothecaries' Hall. It was this. They had no control over
the medical examination, and they were recommended by
the General Medical Council to separate. The College fol-
lowed the Council's advice. They did not separate from the
Apothecaries' Hall because the Hall's examinations were con-
demned. They followed the advice of the Council.

Dr. THORNE THORNE did not come to this meeting with a
decided opinion on this question. He had made up his mind
now. He was the most recently appointed member of this
Council. His first session was last summer's session, and he
must confess he was deeply impressed with the debate that
then took place in regard to the Apothecaries' Hall of Dublin.
It was a very important question, but when the decision was
come to, to report the examination of the Irish Conjoint
Board as insufficient, he had no idea that the action was so
exceptional. He found, however, that in the whole thirty-
seven years of its existence the General Medical Council
had never previously taken so grave and serious a step as to
report a qualifying body to the Privy Council for inefficiency.
After that exceptional action they were, forsooth, actually
asked to prop this body up again. Why, the Privy Council
had not even dealt with the Council's rep
decided last May that they would not com
pending the decision of the Privy Council; if t
now it would lead the General Medical Cou
disrepute, and for that reason he intended to
appointment of examiners.

The amendment was then put to the vote a
by a majority, only 6 members voting for it.

The PRESIDENT asked if the Council we
divide on the original motion.

Sir WILLIAM TURNER said that in Section
1886 it was said: "It shall be lawful for the
from time to time, if they think fit, on the
such corporations, to appoint any number o
assist at the examinations that are held by
tions." Could their counsel, Mr. Muir Ma
them as to what latitude was expressed in t
think fit"?

Mr. MUIR MACKENZIE explained that in a
the Bishop of Oxford was concerned it had
the words "for the Bishop if he think fit" g
discretion and imposed no duty. So there
discretion on the part of the Council under
appoint or not to appoint if they thought fi
Council would forgive him for saying that

the Council to refuse exercising their right.

Sir WALTER FOSTER wished to put th
enactment was intended to be an enabling ar
tive enactment. The intention of Section 5
body like the Apothecaries' Hall of Dublin to
a licensing body, and there was no other sec
of a destructive tendency. Was the bias n
the direction of enabling the body to go on?

The PRESIDENT thought that if the Counc
body should not go on they ought rather to
sentation to that effect to the Privy Council
indirect way of putting an end to the bod
grant examiners for it.

Dr. CHARLES MOORE said he had been to
that he had told an untruth. He thought t
have been said to him. He claimed to be
gentleman. He had been told that he had
saying that Trinity College, Dublin, had off
of use of their theatre to the Apothecaries
to say in reply that he had authority. He h

Moore was not true. He did not say—he
say—that Dr. Moore told an untruth. He be
meant what he said, but that Dr. Moore
information, and it was the information tha
contradict. He regretted that anything he
offended Dr. Moore.

Accumulated Examinations.

Mr. TEALE had given notice of a motion

Digitized by Google

but when called upon to move he asked that he should be permitted to postpone it till next session, and also that it should be entered in the minutes as a notice for that session. The proposed motion was:

"1. That the present system of accumulated examinations, with the consequent enormous increase in the number of rejections, is not only unjust to the medical student, but is damaging to the best interests of medical education.

"2. That the time has arrived when the General Medical Council should consider:

"(*a*) How far examinations and the occasions of rejections can be reduced in number.

"(*b*) How far, whilst retaining effective examinations in those subjects which it is essential that every educated medical man should know and retain the knowledge of, several other subjects, which it is desirable that every medical man should 'know about,' but with the details of which he need not permanently burden his mind, should be removed from the sphere of public examination, the 'bird's-eye survey' of such subjects being secured by compulsory short courses of lectures, aided by class examination by the teacher."

The Council agreed to Mr. Teale's requests.

Midwifery Diplomas.

Mr. WHEELHOUSE presented the following interim report of the Committee on Midwifery Diplomas:

"The chairman reports that the committee appointed by the Executive Committee on Nov. 25th to examine the above subject sat on Thursday, Nov. 28th, but are not yet in a position to report, in consequence of the fact that certain members of the committee had not received notice of their appointment on it, and requests that the committee be reappointed."

Procedure in Penal Cases.

Dr. MACALISTER remarked that the experience the Council had had in the present session of penal cases in which the accused was convicted and sentence deferred showed that some amendment of their procedure was necessary, and therefore he proposed:

"That the Executive Committee be instructed to prepare for the consideration of the Council a suitable form of standing order for the procedure to be followed in cases in which, under the last paragraph of Standing Orders XIV. 14, a decision has been postponed."

Sir WALTER FOSTER seconded the motion, which was at once agreed to.

Attendance on Midwifery Cases.

Dr. LEECH proposed:

"That the Education Committee be requested to consider whether the recommendation of the Council of May 26th, 1888, and reaffirmed May 28th, 1891, with regard to the attendance on cases of midwifery, under the supervision of a registered practitioner, required of candidates for medical qualifications, is carried out, and to report at the May session on this point, and on any modification of the recommendation which they may think to be desirable."

In making this proposal Dr. Leech explained that the resolution of 1888 was to the effect that every student should be required to attend three months' practice in a lying-in hospital and conduct twelve cases of delivery under the direct supervision of a registered practitioner. That resolution was affirmed as the result of a discussion which took place in 1891. Since then many complaints had been made that the recommendation was not being properly carried out. He believed that many boards required attendance on twenty cases, but no notice was taken of the recommendation that these should be conducted under the direct supervision of a practitioner. In looking into the certificates of the various boards he found that to be so. In his view, in all these cases there should be direct supervision, as only in that way could a man be taught all those details which were so important to the lives of patients. There were a good many who thought they did not sufficiently instruct students in practical midwifery, and that was one of his reasons for bringing the subject again before the Council.

Mr. WHEELHOUSE seconded the motion, which was amended by the insertion after the words "carried out" of the words "by the regulations of the different licensing bodies," and was then unanimously passed.

The British Medical Association's Petition.

Sir WALTER FOSTER asked whether the petition on the subject of the registration of midwives, which had been referred to the other day, had yet been received.

The REGISTRAR said he had not received any petition.

Sir WALTER FOSTER understood that the petition was to have been sent on the previous day.

Mr. WHEELHOUSE said he had got what pretended to be a petition, but it was not from the council of the British Medical Association. It was not signed by the President of that Association. It was a paper which had come to him with the signature of the manager of a medical association.

The subject dropped.

Dental Business.

A letter from the British Dental Association relating to a curriculum and degree of Michigan, U.S.A., was referred to the Dental Education and Examination Committee, and other dental business was postponed.

The Council adjourned.

SATURDAY, NOV. 30TH.

The Council resumed, Sir RICHARD QUAIN presiding.

Petition from the British Medical Association.

Sir WALTER FOSTER presented a petition from the council of the British Medical Association asking the General Medical Council to recommend that no student be admitted to his final medical examination until he presents a certificate showing that he has personally conducted at least ten confinements under the direct supervision of a registered medical practitioner.

The petition was referred to the Education Committee.

Examinations in Sanitary Science.

Dr. THORNE THORNE, chairman of the Public Health Committee, presented the report of that committee as to inspection of the examinations in sanitary science of the universities and licensing bodies of the United Kingdom.

The report is a very long document, and we can only find room for the conclusions and recommendations with which it concludes—namely:

"CONCLUSIONS.

"1. We are of opinion that it is necessary to call the attention of some of the licensing bodies to the instruction of the Council to the effect that every candidate on whom a diploma or certificate is conferred should give evidence 'of a distinctively high proficiency, scientific and practical, in each and all the branches of study which concern public health'; and we are of opinion that this instruction should admit of no exceptions, whether on account of the seniority of the candidate or by way of allowing excellence in one subject to compensate for failure in another.

"2. We are of opinion that it is a matter of primary importance that each candidate should, in addition to giving indication of competency in the written and practical examination, display such competency in the oral examination. The oral examination is especially called for in such matters as concern practical epidemiology and the duties of a medical officer of health.

"3. Whilst we are not prepared to advocate a uniform standard for the several examinations, we are of opinion that they should all be regarded as of the character of an honours examination.

"4. We are of opinion that no body conferring a registrable diploma or certificate in Public Health should adopt different standards for different classes of candidates.

"5. We are of opinion that where the examination is rendered in two parts no candidate should be allowed to present himself in Part II. until he has passed in Part I. And we are further of opinion that failure in any one subject in either part ought to entail rejection in the whole of that part.

"6. We are of opinion that practical bacteriology should form a distinct part of every examination for a diploma or certificate in Public Health.

"7. We are of opinion that practical examination in the routine work of a medical officer of health, including a test of ability properly to interpret plans, should form part of every examination for a diploma or certificate in Public Health.

"8. Whilst we attach great importance to the possession by every successful candidate of distinctive competency in relation to the clinical aspects of the infectious diseases, we are not prepared to say that practical examination in this matter should in every case necessarily form part of the examination.

"9. We are of opinion that a practical knowledge as to the wholesomeness of food-supplies, including meat in the form of carcase, should be regarded as properly coming within the scope of an examination which aims at providing expert medical officers of health.

"10. In conclusion, your committee desire to express their opinion that so many of the licensing bodies should have thought fit to institute examinations and to grant diplomas and certificates in Public Health. The multiplication of such examinations, quite irrespective of the number of candidates, is, in our opinion, not conducive to the maintenance of the standard of efficiency which should be aimed at.

"RECOMMENDATIONS.

"I. We recommend that this report should be communicated to all the bodies having the power to confer registrable diplomas or certificates in Public Health, for their information.

"II. We further recommend that on the expiration of a period sufficient to enable the bodies concerned to bring their examinations into conformity with the views of the Council, a re-inspection of the several examinations should be made."

Several members of the Council took exception to criticisms made by the inspector and the committee with regard to the examinations of their respective bodies, but in every instance they avowed an earnest desire to maintain a high standard of proficiency and observe all the recommendations of the Council.

Dr. THORNE THORNE moved the adoption of the report and the recommendations it contained.

Sir WILLIAM TURNER, in seconding this motion, said the Council might well congratulate itself on the admirable

Digitized by Google

er of the report and the practical usefulness of its
ions and on the fact of possessing such a committee.
BRUCE endorsed what Sir William Turner had said
d a compliment to the chairman of the committee.
PRESIDENT said he regarded this as a model report.
report was then adopted by the Council.

Diplomas in State Medicine.

the motion of Dr. THORNE THORNE, seconded by
ALE, it was agreed :

t the Rule 1 (3) adopted by the Council on Dec. 1, 1893, for
s in State Medicine be amended; and that the rule be as

Every candidate shall have produced evidence that, during a
f six months after obtaining a registrable qualification, he has
ractically studied the duties of out-door sanitary work, under
lical officer of health of a county or of an urban district having
late of the last census a population of not less than 50,000 or of
ination of two or more sanitary districts having collectively at
e of the last census a population of not less than 35,000, or else
self held an appointment as medical officer of health under con-
not requiring the possession of a special sanitary diploma. The
ate of an assistant officer of health of a county or a large urban
may be accepted, provided the medical officer of health of the
or district consents to the assistant officer giving such instruc-

as explained that the existing rule was felt to be a
hip, and that the new reading would be more consistent
present-day conditions.

The New Recommendations for Examinations.

DYCE DUCKWORTH moved the adoption of the recom-
ations of the Examination Committee as amended by
ouncil in committee on Thursday.

BRYANT seconded the motion.

GLOVER proposed the deletion of the twelfth recom-
ation—"That, as the art of examining is only to be
red by practice, it is desirable that an examiner should
elected, where practicable, for at least five consecutive
, particularly for the final examinations." He held
half the rejections of candidates were owing to bad
iners rather than to inferior attainments on the part of
students, and what he feared, if this resolution was
ed, was that there would be a tendency to establish a
examiner for five years.

DYCE DUCKWORTH explained that the recommendation
simply intended to indicate that it would be within the
er of the examining bodies to re-elect examiners. That
t mean annual re-election. It would be within the
er of the examining bodies to discharge an examiner.

r. TEALE hoped the Council would allow this recom-
dation to stand. He regarded it as a pronouncement on
part of the Council that the matter of examining was a
serious one.

r. GLOVER said he would not press for its removal.

r. BATTY TUKE wished to draw attention to the fact
the second recommendation—"That the extreme sub-
sion of any subject of examination, and particularly of
final, as now permitted by some boards, should not be
ctioned"—practically repealed an existing standing
mmendation which was passed in 1888. In that old
mmendation it was laid down that candidates for the
l examination should not be allowed to present them-
es for examination in the various subjects separately. In
new recommendation they would approve of the various
jects being taken separately. They only objected in it to
ividual subjects being broken up piecemeal. This he
ught was a complete change of the system which had
n going on since he became a member of the Council.
submitted that it was a change of principle and the
eal of a standing resolution of the Council.

Mr. BRYANT pointed out that whatever might be said as to
nciple there was no change of practice, for it had been
rule in most examining bodies to allow men to go up in
dicine, surgery, and midwifery separately. Good men
ght be able to pass in the three subjects at one time, but
most men it was impossible to do so. If they were to
mpel the boards to re-examine in the three subjects men
icked in one they would have such complaints that the
e would soon be abolished altogether.

Dr. MCVAIL expressed disappointment with the attitude
at the committee had taken up on this matter. It was a
markable thing that the representative of the great
llege of Surgeons of England should tell them at this time
day, and after all that had been done to establish a
tisfactory curriculum, that the candidates who went to that
llege could not be up in medicine, surgery, and midwifery
at the end of the five years' study, and must
take each subject separately—that was, to c
examination in medicine after passing in su
midwifery after passing in medicine. He
College believed that if the candidates went u
subjects at one time they would fail. H
emphatically that the final examination, that w
to the Register, should be an examination
surgery, and midwifery, and unless a man we
three subjects at one time he should be given f
which to pass.

Mr. TEALE said that what Dr. McVail

extreme sub-division meant such piecemeal examination as would permit a pass in a subject after two remits, there being examination at the candidate's second appearance only in the part or parts (which might be the oral and clinical, or one of these, a pass having been secured in the written) in which there was failure at the first trial, and examination at the third appearance only in the part or parts in which there was failure at the second appearance.

Sir WALTER FOSTER thought the committee were quite right in condemning that system.

Mr. BRUDENELL CARTER said it appeared to him that the meaning of the second recommendation was that in the final examination they disapproved of the sub-division of any one of the subjects. He saw no reason why they should not say so. Personally he wished to get rid of the word "extreme," and he proposed: "That the sub-division of any one subject of examination, and particularly in the final, as now permitted by some boards, should not be sanctioned." If the Council passed that they would mean that the bodies must not break surgery into two or three examinations, medicine into two or three examinations, or midwifery into two or three examinations, and having made that statement they were in a position to follow it with the recommendation passed in 1893.

Sir DYCE DUCKWORTH accepted this suggestion.

It was thereupon agreed that the amended resolution should be the second recommendation, and that it should be followed by the resolution of 1893 as a separate recommendation. The latter is as follows:

"Seeing that the practice of different authorities varies on the question whether a student who fails to satisfy the examiners in each of the several subjects of medicine, surgery, and midwifery should be referred on all of them, or only on those in which he fails, the Council recommends that some general principle should be adopted with reference to this question; and suggests that a percentage of not less than 60 marks on each of any two subjects—supposing that the pass requirement be 50 per cent.—should exempt from re-examination in those two subjects."

Dr. PETTIGREW moved that the first recommendation be amended by the insertion of the words "at least" before the words "two academic years."

This proposal was seconded by Dr. MACALISTER, and was adopted by a majority—14 to 8.

On Section (*a*) of the eleventh recommendation—"That the marks obtainable on the written examination ought not to have greater weight than those at the oral or clinical examinations"—Dr. MCVAIL moved that when a candidate had in clinical medicine or in clinical surgery a mark awarded that was below the pass mark, the mark should not be raised because of any excess of marks in the oral or written parts of the examination.

Mr. BRYANT opposed this proposal, which was rejected by a majority.

The Council adjourned till Monday.

MONDAY, DEC. 2ND.

The Council resumed, Sir RICHARD QUAIN presiding.

The New Recommendations for Examinations.

On the motion of Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, the following additional recommendation was agreed to—viz., "That in whatever subject or part of a subject a candidate may be rejected satisfactory evidence should be produced that he has carried on his study in that subject during the interval of his remission, and such a candidate should not otherwise be eligible for admission to re-examination." Many of the examining bodies, Mr. Bryant said, carried out this plan, and this recommendation would strengthen their hands and encourage the others to follow their example.

Dr. MACALISTER moved:

"That the resolutions on professional examinations, approved by the Council in committee, and by the Council itself, be remitted to the Examination Committee, with instructions to consider them in relation to the existing recommendations on the subject, and to draw up in a consolidated form a series of definitive recommendations suitable for transmission to the licensing bodies."

Dr. BATTY TUKE seconded the motion.

Dr. HERON WATSON said this was a matter of some urgency, and he thought the delay of six months might be avoided by the chairman of the committee drawing up such a code and sending it round among the members of the committee.

Dr. MACALISTER thought, however, that the final form should be submitted to the Council for its approval.

Dr. HERON WATSON said that he had already written to Edinburgh suggesting that the committee of manage[ment] the Scotch Triple Board should meet at once to bring regulations into conformity with these recommendations. This would certainly be a mistake if the recommendations were to be submitted again to the Council.

Dr. MACALISTER said he took it that the principle of the recommendation had been finally approved by the Council and that consequently the examining bodies could have no doubt as to what the Council desired.

Sir WALTER FOSTER moved, as an addition to the motion, "and also that reference be made to the report of the inspector on which each new recommendation is based." He thought that the bodies who were at fault should be clearly indicated.

Dr. BRUCE seconded this proposal, agreeing that there should be direct reference to the bodies at fault.

Dr. MACALISTER accepted the addition, and with it the motion was carried by the Council.

The Scottish Branch Council.

A report by this Council as to the registration of names and diplomas of two gentlemen was brought up and agreed to.

The Misuse of Medical Titles.

The Council spent some time *in camerâ*, and when the public were readmitted the PRESIDENT intimated that a statement had been conveyed to the Council with regard to a person who had no qualification at all in this country calling himself M.D., sending out indecent pamphlets, and advertising medicine, and that the Council had resolved to refer it to its Penal Committee to inquire into cases of persons alleged under Section 40 of the Medical Act of 1858, and what the committee saw fit to instruct the legal adviser to proceed against such persons.

The Apothecaries' Hall of Dublin.

Sir WILLIAM TURNER moved:

"That if the Privy Council should notify to the General Council their opinion, and issue any directions, on the points submitted to the General Council regarding the examinations of the Conjoint Board of the Royal College of Surgeons and Apothecaries' Hall in Ireland; also on the decision of the General Council to grant the petition of the Apothecaries' Hall that the Council appoint assistant examiners under the Medical Act, 1858, the Council empowers the Executive Committee to explain to the Council the grounds on which the General Council have arrived at their conclusion, and to take any further steps that may be necessary."

This motion, he explained, was framed strictly in accordance with the Act of Parliament. It had been felt by the Business Committee and by the President that if the Privy Council expressed any opinion to the Council upon any of these questions, or if the Privy Council issued any directions to them, the Council should have some means of replying to the opinion or directions, and, if necessary, making a representation thereon.

Mr. WHEELHOUSE seconded the motion.

Dr. MACALISTER pointed out that no notification had been made to the Privy Council as to what this Council had done.

Sir WILLIAM TURNER said that the point had been considered, and it was thought that the Apothecaries' Hall would notify the matter to the Privy Council because Dr. MacAlister were to look at the Act, he would find that it was the duty of the body to make the application to the examiners. This Council refused the application, and the next step, he apprehended, would be for the body who had been refused to make a representation to the Privy Council to issue directions to this Council. That was how he read the sequence of events under the Act. If the Apothecaries' Hall rested satisfied, then there was an end to the matter.

Dr. CHARLES MOORE assured the Council that the Apothecaries' Hall would take whatever steps were necessary to maintain its legal status. He hoped to see the Governors on the following day and to confer with him on the subject.

Dr. GLOVER moved as an Amendment that the Council transmit to the Privy Council the minutes of the meeting bearing on this subject. He thought this would be proper and courteous.

The PRESIDENT ruled that this was not an amendment.

Thereupon the motion as proposed by Sir William Turner was adopted.

Students' Registration.

Sir DYCE DUCKWORTH presented a report from the Students' Registration Committee, containing, among other things, the following recommendation:

"That while (according to Resolution 11, Vol. xxvii., p. 58) [persons] who, prior to 1892, passed the preliminary examination of the Pharmaceutical

Digitized by Google

ociety are entitled to register as medical students on taking the y omitted subjects, they must show that they were engaged as students of medicine before 1892 and preparing for the com- their examination; and that on and after January 1st, 1897, on on these exceptional conditions shall cease, and evidence, case, be produced that all the subjects have been passed at the e at one of the examining bodies now recognised."

a short discussion the recommendation was adopted form: "That on and after January 1st, 1897, the tion of students under Resolution 11 of June 2nd, 1891, be discontinued, so far as concerns the preliminary ation of the Pharmaceutical Society."

anks to the Royal College of Physicians of London.

following motion, proposed by Mr. WHEELHOUSE and ed by Sir WILLIAM TURNER, was cordially adopted:

the thanks of this Council be conveyed, through its President, resident and Council of the Royal College of Physicians for their in granting the use of their library and other rooms and es for the session of this Council and for their kindly hospitality Council."

Thanks to the President.

GLOVER proposed a vote of thanks to the President able conduct in the chair. Sir Richard Quain had hrough his work in most admirable manner, and he re that all the members would wish to congratulate

PHILIP SMYLY seconded this motion, adding "long e live to reign."

PRESIDENT said that if he had done anything he had t with pleasure, and the greatest reward he could think s the approbation of those he saw around him. As s he was spared he would do his best to continue to that approbation.

session was thereupon brought to a close.

Medical News.

NEW MEDICAL DEFENCE ASSOCIATION—The annual meeting of this society was held at the offices of the company, 15, King-street, Cheapside, on Nov. 27th. Dr. Leslie Phillips, who occupied the chair, pointed out that the society constituted a well-equipped defence organisation, the powers of which were confined to the original and proper conception of medical defence against attacks from the public, unjust charges, malpraxis, &c. The society could not interfere in litigation between medical men, neither did it spend the subscriptions of the members in prosecuting unqualified practitioners, a function the onus and privilege of which was vested by the legislature in the Society of Apothecaries. As the result of the first year's operations £200 had been invested in Consols, and a considerable sum in cash was in hand. The cost of administration was very small, and the membership was steadily growing. The report and accounts were adopted unanimously.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND. — The annual general meeting of this society was held at Guy's Hospital on Nov. 22nd. Professor Thane was elected president in place of Professor Cunningham. The treasurer's account was adopted, and showed a balance of £76 2*s.* 6*d.*—Dr. G. F. Blacker read a paper on the Topographical Anatomy of the Fourchette. In it he pointed out the discrepancies which exist in the descriptions of this part in different text-books. He then gave some statistics from the observation of 397 patients attending his out-patient department. The most important of these showed that in about 15 per cent. the fourchette was formed by the united posterior extremities of the labia minora, while in the rest it was a fold of skin apparently uniting the posterior extremities of the labia majora.—Mr. F. G. Parsons read a paper and showed drawings of a rare form of Parasitic Fœtus lately added to the museum of the Royal College of Surgeons of England. The paper contained an account of the dissection of the different systems.—Mr. A. Keith read a paper upon the Frequent Occurrence of a Divided Inferior Vena Cava in the Genus Hylobates (Gibbons). In it he discussed the development of the veins of the abdomen, and criticised Hochstetter's views.—Mr. Higgins showed a series of specimens illustrating the True Capsule of the Knee-joint.

THE DIFFUSION OF SMALL-POX.—The amount of small-pox both in London and in the suburbs during the week ended Nov. 30th was less than for several weeks previously, and there were only 9 admissions in all to the hospitals of the Metropolitan Asylums Board. There was, however, one death registered, the deceased being an unvaccinated infant who died on board the hospital ship *Atlas*. In addition there were two deaths registered in West Ham, where the disease has been causing some alarm of late. The close of the week found 79 patients under treatment in hospital suffering from small-pox. Thus once again we find the metropolis with a waning prevalence of small-pox, and it will be well if the amount of the disease continue to decline during the winter months. In Bristol there is some fear on the part of the authorities lest the cases of small-pox found to have developed in the workhouse should foreshadow a winter prevalence, and the authorities of surrounding unions have been specially warned to keep a sharp look-out for symptoms of the disease in tramps. It is considered likely that infection has already been introduced to the Poor-law institution at Bristol by the agency of vagrants, as on several occasions during the recent epidemic in that city. Dr. Davies, the medical officer of health, thinks that the cases may also have some connexion with the appearance of small-pox in Gloucester. He has warned medical men of the importance of an early diagnosis of the disease, and has advised measures of vaccination and revaccination in institutions of various kinds in the city. A case which arose last month in Yeovil in a young man lodging in the town has been removed to the hospital just outside the borough boundary, and the whole of the members of the infected household also consented to accompany the patient to hospital. It is much to be hoped that no harm may accrue from this action if it be an accomplished fact. A case has been reported to the medical officer of health of the Barry district, but the officer has been unable to agree with the diagnosis. During recent weeks there have been two or three cases notified at Manchester, and the sufferers have been removed to the Clayton Hospital, but the adjacent borough of Salford has remained free from the disease. In Dublin, in the week ended Nov. 23rd, there were 3 fresh cases admitted to hospital and the same number of discharges, and consequently, there being no deaths, remained in hospital a total of 11 patients, as on the preceding Saturday.

SUNDAY LECTURE SOCIETY.—The second series of lectures given by this society will begin on Dec. 8th, at St. George's Hall, Langham-place, at 4 P.M., when Dr. Benjamin Ward Richardson will lecture on the Rise of Capital Punishment. Lectures will subsequently be given by, among others, Professor Arthur Smith on the Anatomy of Flame, and Professor Percy Frankland on Isaac and his Work.

DIPHTHERIA IN LONDON.—Diphtheria in its fatal form was, in the week ended Nov. 30th, less prevalent in London than in the week before, the 69 registered deaths of the earlier week falling to 63 last week. The decennial average for the forty-eighth week of the years 1885-94 was nevertheless exceeded by as many as 7. The deaths were again nearly all in young persons aged from one to twenty years. There were 6 respectively belonging to the sanitary areas of Lambeth, Fulham, and Islington Green, and 5 each to St. Pancras and Greenwich. Only 86 cases were admitted to hospital in the week, as compared with 112, 104, and 103 in the three preceding weeks. The cases remaining under treatment on Saturday numbered 691, a total higher than that recorded for some time. Around London, in the Outer Ring, there were 10 deaths from diphtheria registered last week, and of these 7 belonged to the West Ham district, the majority of the suburban areas being quite free from the disease.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BAIRD, JOHN, L.R.C.P. L.R.C.S. Edin., has been appointed Surgeon to Lady Dickson Lodge, Dover Branch of Female Oddfellows.

BROWN, ROBERT C., M.B., B.C., B.A. Camb., has been appointed Second House Surgeon of the Blackburn and East Lancashire Infirmary.

CALWELL, WM., M.A., M.D. R.U.I., has been appointed Assistant Physician to the Belfast Royal Hospital, vice Dr. R. S. Smyly, promoted.

DICKSON, R. S., M.B., C.M. Glasg., has been appointed House Surgeon to the Whitehaven and West Cumberland Infirmary.

DOUGLAS, W. T. P., M.B. Camb., M.R.C.S., has been reappointed Honorary Medical Officer to the Children's Cottage Hospital, Cold Ash.

GODSON, J. H., M.B., B.C. Camb., has been reappointed Medical Officer of Health for Cheadle.

HAMILTON, W. CROSBIE, M.B., C.M. Ed., has been appointed Senior House Surgeon of the South Devon and East Cornwall Hospital, Plymouth.

HEWLETT, J. E., M.B., C.M. Edin., has been appointed Junior Assistant Surgeon to the Blackburn and East Lancashire Infirmary.

JARDINE, ROBT., M.D. Edin., M.R.C.S. Eng., F.F.P. and S. Glasg., has been appointed Assistant Physician to the Glasgow Royal Hospital.

KERBY, R. J., M.D. Brux., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Medical Officer to the Children's Cottage Hospital, Cold Ash.

LAKE, W. W., M.R.C.S., has been reappointed Medical Officer to the Woking Urban District Council.

LYON, F. H., L.R.C.P., L.R.C.S. Irel., has been reappointed Consulting Surgeon to the Children's Cottage Hospital, Cold Ash.

LYONS, EDWARD, B.A., M.B., B.Ch. B.A.O. T.C.D., L.M. Rotunda, has been appointed Junior Resident Surgeon at the Jervis-street Hospital, Dublin.

MCENIRY, JAS., J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Health Officer for the Shire of Charlton, Victoria, Australia.

NIALL, W. G., M.D., M. Ch. Irel., has been appointed Medical Officer for Wanborough, Surrey.

PRINGLE, G. L. KERR, M.B., C.M. Edin., has been appointed Medical Officer for the No. 3 Sanitary District of the Bridgwater Union, vice Cooper, resigned.

RUDALL, JAS. T., F.R.C.S. Eng., has been appointed a member of the Medical Board of Victoria, Australia, vice R. W. Jones, resigned.

SAUNDERS, F. W., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been reappointed Honorary Medical Officer to the Children's Cottage Hospital, Cold Ash.

SMITH, J. A., M.R.C.S., has been appointed Medical Officer for the Flockton Sanitary District of the Dewsbury Union.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

IDEATION AND NOCTURNAL ENURESIS.

To the Editors of THE LANCET.

SIRS,—On Oct. 18th, 1890, you published a letter from me on the above subject. The importance of ideation in the treatment of disease is my excuse for again directing attention to it: the administrator is frequently of more importance than the drug administered.

In the first week of October, 1895, a patient lamented to me that her granddaughter was unable to do anything to earn her living, as for thirteen years she had wetted the bed every night. The granddaughter was anæmic, well grown, aged fifteen, menstruating regularly, with depressed countenance owing to her malady. I prescribed colocynth and iron. I impressed on her strongly that the misfortune need not and could not recur; that on going to bed she was to remember my statement that the accident could not recur, and that the spine would have to be severely blistered if she did not believe me and the accident did happen. The enuresis did not recur until the sixth night. I spoke very seriously to her about not *believing* me and doubting whether the accident could occur. The enuresis did not again recur till the sixteenth night. I now talked to her very gravely, but consented to give her one more chance before punishing her for her unbelief. She is now bright, cheerful, and well, having had no further recurrence, and is preparing to take up employment away from home.

I am, Sirs, yours faithfully,

Framlingham, Suffolk, Nov. 25th, 1895. GEO. H. JEAFFRESON.

UNIVERSITY CAMPS FOR PUBLIC SCHOOL BOYS.

LIEUTENANT-COLONEL AND BRIGADE-COMMANDANT SETON CHURCHILL sends us the following particulars about university camps, which will no doubt interest our readers:—

"There were about 400 boys and young men from all seats of education encamped this year, distributed throughout five camps. The following places were represented: Oxford, Cambridge, Edinburgh, Durham, London, and other Universities; Woolwich, Sandhurst, and H.M.S. *Britannia*; Eton, Harrow, Winchester, Charterhouse, Westminster, Wellington, Cheltenham, Clifton, and all the great public schools and leading private ones. The five camps were at Bamburgh (Northumberland), Abergele in North Wales, Deal, and an early and a late camp at Highcliffe (Hants). Each boy pays 4*s.* per diem. The boys have to do everything for themselves in the way of making beds, airing bedding, cleaning up knives, forks, spoons, plates, peeling potatoes, &c. We have in each camp one soldier cook, but no servants, so these upper-class boys are taught to rough it a bit, as they would have to do in a colony or on a campaign. The days are spent in bathing, boating, sailing, cricket, cycling, football (if not too hot), rambling or walking parties to places of interest in the neighbourhood, athletic sports, boxing, singlesticks, &c. The evenings are spent in concerts, reciting, debating, &c. Each evening before going to bed a church parade is held, which is an earnest, bright mission service for boys. No unhealthy excitement is encouraged, but an earnest spirit of deep religious enthusiasm is cultivated. Boys have special temptations, so special efforts are required to reach them. A manly, healthy form of Christianity is presented to these bright young lads, and they respond wonderfully. Each camp is in charge of a military officer, and each tent, containing seven, is in charge of a university undergraduate, who is selected as one who will make religion attractive to boys, and not present it in a gloomy form. Each camp has a medical officer in case of accidents, but so far his professional duties have been quite nominal. These camps were first started in 1892, with eighty boys. The following year there were about 180 boys, in 1894 there were about 300, and in 1895 they amounted to about 400, so the popularity of the movement speaks for itself. The boys bring each other. Each camp lasts about ten days. The movement was started by Cambridge undergraduates, but in 1893 it was seen that the numbers would increase and that some organising power would be required, which young men could not be expected to have, so it was decided to appoint a head, and they did me the honour to elect me Brigade Commandant, but I am not the originator. The idea was borrowed from the Boys' Brigade, which is an excellent effort to reach boys of a lower strata of society by similar means. The Camp Commandants this year were Major-General McCausland, Colonel Morton, Lieut.-Colonel Phayre, Lieut.-Colonel Seton Churchill, and Major Liebenrood — all military men. The medical officers thoroughly enjoy the ten days' holiday at the seaside, and pay their share of expenses—4*s.* per diem—and make no charge. Capital fellows."

Puzzled.—We can only indicate the broad lines of conduct; we cannot be anyone's professional conscience. In answer to our correspondent's queries we think: (1) no breach of etiquette has been committed; (2) a copy might be sent to the managers of the schools; (3) and (4) copies might be sent to our correspondent's own patients; and (5) we cannot answer. It would be certainly a form of advertising to disseminate copies widely, in lay circles, or among other practitioners' patients.

Dr. Jas. H. Nicoll.—A copy of our correspondent's letter has been sent to our reviewer.

PURPURA.

To the Editors of THE LANCET.

SIRS,—The following case may be of interest to some of your readers. On Nov. 2nd, at 9 A.M., I was called to a woman aged thirty-six, living in a village near this town, and found her suffering from colicky pains, a little diarrhœa, a temperature of 101° F., and little else of diagnostic importance. She was the subject of chronic mitral disease. I prescribed opium, and she was soon relieved of the pain. On the following morning, at 2 A.M., I was again sent for, and found her in a similar condition, the temperature being 103°, and with the addition of pains in the backs of the legs. Dr. Sunderland saw her later on in the day; a large number of purpuric spots had then developed, interspersed with a few blebs containing red and white serum, and some pustular spots. When I saw her again the next morning I discovered a huge swelling of the glands of the neck, which was more than twice its usual size, large purpuric patches and petechiæ over this region, and smaller purpuric spots and vibices over other parts of the body; the temperature was 106°. She was quite unconscious, with a rapid pulse, and died a few hours afterwards. She had lately been nursing a woman with paralysis and had dressed her bed-sores. I remember while at the Middlesex Hospital four or five fatal cases of purpura occurring in the same ward in the space of about three weeks, and which appeared to me to be of bacillary connexion. I should be glad to know if any of your readers have had similar experience, and what is the general belief as to the origin of purpura.

I am, Sirs, faithfully yours,

Thaxted, Essex, Dec. 2nd, 1895. EDGAR PITTWAY.

THE POPULATION OF ENGLAND AND FRANCE.

THE question of the growth of France and the United Kingdom respectively in point of population has been frequently made a basis of comparison and comment, and an interesting and instructive article in the *Standard* of the 3rd inst. on the relative positions of the two countries in this respect is well calculated to arouse attention. The facts are very striking and remarkable. In 1801 France had a population of eleven and a half millions more than the British, but this French superiority in numbers had in 1891 shrunk to little more than half a million. According to calculations based on official returns it would seem that at the present date the population of this country probably exceeds that of France by one million. Although the number of marriages in France is greater than that of England, the actual and relative birth-rate, as compared with the death-rate, is much higher in the latter country. Our contemporary thinks it may be pretty safely predicted that by 1901, when the first census of the twentieth century is taken, it will be found that, in spite of four times as large a foreign immigration and a considerably larger number of marriages in France as compared with this nation, the population of the United Kingdom will have probably outstripped that of France by about two millions, notwithstanding, too, the vast emigration that has been going on from this country as compared with that from France.

L. W. H.—The specimen which our correspondent has sent to us is not a nerve at all, and the supposed arteries which he has observed springing from it are merely a felted network of the threads of fungi. The theories he bases on this incorrect observation with regard to the nature of arteries, veins, and nerve force are entirely contradicted by known facts, of which our correspondent can easily satisfy himself by observation. We should recommend him to purchase "Physiology for Beginners," by Foster and Shore published by Macmillan, and to investigate for himself, on the body of a dead cat or rabbit, the appearance and function of the different structures and organs of the body. He will be able to see that arteries, veins, and nerves are structures quite distinct one from another, and he will abandon the revolutionary doctrines on consciousness, &c., which he is anxious we should promulgate.

Enquirer.—It is not only allowable to append to the letters M.D. or M.B. the name of the University which granted the degree, but it is a most desirable practice.

"WANTED, A MILK STERILISER."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 30th a correspondent asks for information as to a milk steriliser; and as I have found the following apparatus very efficient during the past summer, I venture to recommend it to him. It has the advantage of being procurable everywhere, and all the parts can be easily replaced if broken.

A one-gallon iron saucepan, a *gourmet* boiler to fit it, a dozen round, white, long vials of 2-oz. capacity, such as are used in dispensing, and a pound of cottonwool. Another very useful adjunct is a frame (like a cruet-stand) to hold the bottles; it can be made of tin and galvanised wire by any ironmonger to fit into the *gourmet* boiler. The bottles are thoroughly washed with soda and water, and then rinsed with clean water; each has poured into it the quantity of milk the child requires for one feed, and the neck of the bottle is plugged with cottonwool. The bottles are placed in the frame, the frame is lowered into the boiler, and cold water poured into the latter until it reaches as high as the top of the milk in the bottles. The lid of the boiler is put on; about a pint of water (hot or cold) is then poured into the saucepan, and the *gourmet* boiler lowered into it. Place at the side of the fire, and gently boil the water in the saucepan for from half an hour to an hour. The milk in the bottles does not boil, but reaches a temperature of about 180° F., as shown by the thermometer. A handle on the frame enables it to be removed with the bottles, and also serves, if necessary, for carrying them about. The great disadvantage of the various milk sterilising apparatus in the market is the trouble or impossibility of replacing bottles or parts that are broken. The apparatus described can be obtained in every village; it is cheap, and is easily replaced. The description of the method of using the steriliser looks very formidable, but it is quickly learned and easily carried out in practice, and is the same for every form of apparatus.

I am, Sirs, yours truly,

East Twickenham, Dec. 2nd, 1895. H. HOWARD MURPHY.

*** We may draw attention to a notice of Waldstein's milk sterilisation apparatus, which is supplied by Messrs. Philip Harris and Co., Limited. (*Vide* THE LANCET, April 20th, 1895, p. 986.)—ED. L.

Alpha.—We should require to know more of the conditions in detail of *Alpha's* appointment before we could answer the question put to us. At a first glance we should be disposed to advise *Omega* not to join a partner handicapped with such an appointment.

H. E. C. K.—We can under no circumstances recommend individual practitioners or courses of treatment.

A WORD FOR ALCOHOL.

A CORRESPONDENT writes:—"Matthew Arnold had a poor opinion of Carlyle because the Chelsean sage preached diligence to a nation already far too zealous in the pursuit of utilitarian as opposed to ornamental things. It cannot be denied that this is the age of restlessness, of over-exertion, and worry, or, as our Gallic friends call it, *surmenage*. Competition, born of love of luxury and fostered by over-population, is so severe that even sluggards are induced to do violence to their natural inclinations by hard work, while people with an aptitude for toil are irresistibly driven to excess. These *obiter dicta* are *à propos* or not, as the case may be, of teetotalism. One favourite argument with total abstainers, based upon the experiments of Kraepelin and others, is the inhibitory action of alcohol upon the brain. A recent writer sums up the question in the following: 'I have quoted enough to prove that even in small doses alcohol does not stimulate but retards vital processes.' Now this is precisely what the too-zealous worker requires. Alcohol prevents the human machine from wearing out prematurely. The neurasthenic brain-user takes his customary dose in the shape of wine, spirits, or more humble beer, and forthwith finds himself, *nolens volens*, incapacitated from continuing his labours. He is compelled to allow his weary brain the rest which otherwise he would deny; alcohol, the fiend alcohol, becomes his guardian angel, saving him from cerebral exhaustion, if not from softening and utter demoralisation." But Mr. Smith thinks differently.

INTEMPERANCE.

MR. CHARLES SMITH, Secretary of the Kent County Temperance Federation, has sent us a paper which he suggests will be useful reading to ourselves and our readers. We have read the paper; but we do not reproduce it, because it has been of no use to us, and in our judgment could not possibly be of any use to anyone else. Mr. Smith is sure that our qualified approval of an issue of rum to the soldiers on march in the Ashanti expedition is very pernicious doctrine. He reinforces his opinion with quotations from the late Professor Parkes and the late Surgeon-General Maclean, and a reprint of an address delivered by himself and published in the *Kent and Sussex Courier* on "Temperance Principles in Science and Morals." We have said what we believe to be right, but are willing to respect other people's opinions.

NITRITE OF AMYL DURING CHLOROFORMISATION.

To the Editors of THE LANCET.

SIRS,—The value of nitrite of amyl in the treatment of threatened heart failure during chloroform anæsthesia appears to depend very largely upon the stage when it is administered. Drs. Gaskell and Shore maintain that the effect of chloroform upon the vaso-motor centre is one of stimulation, whilst simultaneously exercising a depressing influence directly on the heart. As the result of some recent observations I have been making on the pulse tension of patients under chloroform have come to the conclusion that one of the earliest effects of an overdose of the anæsthetic is arterio-capillary contraction. The vessels by thus contracting seem to exert a kind of stop-cock action in order to prevent the blood, dangerously loaded with chloroform, from reaching the tissues. At the same time the heart is directly depressed, and tends to yield to the peripheral resistance. This condition of virtual high pulse tension lasts only for a brief period, but that it does exist is proved by numerous sphygmographic tracings; it is quickly succeeded by a rapid fall of blood-pressure. The heart, itself depressed by the anæsthetic, has not sufficient power to go through its systole in the face of the resistance in front. It is at this initial stage of heart failure that nitrite of amyl is invaluable; after the inhalation of three or four minims the peripheral vessels relax, the resistance to the discharge of the left ventricle is diminished, and the threatened paralytic over-distension is averted. I am, Sirs, yours faithfully,

J. H. MARSH, M.R.C.S., L.R.C.P.,
Senior House Surgeon.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Asnieres, Paris.

"*The maintenance of Nutrition is the KEYNOTE of the successful treatment of Phthisis.*"—
THE LANCET.

Bynol. "The Perfected" Malt & Oil.

Physiology.

This can be best considered by taking separately its two constituents:—

1. The **Malt Extract** used contains an amylolytic ferment called diastase, of the fullest activity. Its special function of converting starchy foods into a soluble sugar which can be easily absorbed renders this preparation at once invaluable for aiding assimilation.

In weakly and cachectic conditions the activity of the natural allied ferment ptyaline becomes greatly deficient, with the consequence that much ingested material is never digested.

The Malt Extract being semi-fluid, and possessing a characteristic sweet taste, is therefore physically a very convenient vehicle for emulsifying and disguising the slight taste of the other constituent—**Cod Liver Oil.**

2. The physiological properties and fate of the latter body are complex; its equivalent in heat-units as regards the animal body is at least two-and-a-half times that of Meat Extract (Liebig); that is to say, it is at least two-and-a-half times as valuable as Meat Extract in maintaining the body weight.

Long use has shown that, in atrophic conditions of the absorbing mechanism of the bowel, Cod Liver Oil is not only more easily emulsified, but more easily taken up by the villi of the small intestines and passed on to the lacteals.

In the "**Perfected**" **Cod Liver Oil,** where the formation of certain oxidation products irritating to the stomach is avoided, we have perhaps the ideal form of fat-food.

Milk, cream, etc., are liable to produce butyric and other allied fatty acids, of little use except to irritate the gastric and intestinal mucous membrane.

To more perfectly understand the part played by Cod Liver Oil, the digestion of fat-foods is roughly as follows:

In the stomach slightly, but chiefly in the duodenum, by the action of the pancreatic ferment, fats are—

1. *Emulsified*, that is, broken up into minute oil globules, each surrounded by what is known as a haptogen membrane. In this physical state absorption is possible by the villi, the oils being unaltered.

2. *Saponified*, that is, split into fatty acids and glycerine, both capable of absorption by the intestine.

Therapeutics.

The above considerations enable us to understand more clearly the immense use Malt Extract and Cod Liver Oil, especially in combination, have in wasting diseases.

In *Phthisis*, for example, the digestive ferments are of lowered activity, and the introduction of a modicum of artificial ferment not only increases the actual amount of food assimilated, but the power of the enfeebled ferments to assimilate.

The almost constant rise of temperature above the normal is maintained chiefly at the expense of the fatty constituents of the body; hence the wasting. This, experience has shown, can best (putting aside questions of hygiene) be combatted by increasing considerably the amount of fat-food and carbohydrate food.

When absorbed, the part played by fat-food is practically two-fold:—

1. It becomes the source from which the surplus fat stored up in various parts of the body may be replenished.

2. Fat-food is one of the chief sources of animal heat, as shown above.

As we have seen, the Cod Liver Oil is the best of the class of fat-foods, especially in an enfeebled condition, and, combined with Malt Extract, as in Bynol, further assists the assimilation of the extra carbohydrate ingested.

That what is physiologically is also clinically true cannot be better illustrated than in the remarks made by the late Sir ANDREW CLARK in a lecture at the London Hospital:—

"I have said that these fibroid cases are poor creatures, thin and white, and have what may be called nutritive debility, and the question is, What am I to do with them? You cannot do better than endeavour to make the patient walk in the way of physiological righteousness. But that sometimes will not do. Some people may be physiologically well behaved, and somehow they do not thrive on it. Can you do anything in those cases? There are two remedies which sometimes do succeed where the ordinary diet will not succeed in nourishing the patient—the one is Cod Liver Oil and Malt given with food—a preparation called Bynol—and the other is the remedy called Bynin Emulsion, consisting of Hypophosphites, Oil, and Malt; both are prepared by Messrs. ALLEN & HANBURYS. These are two good nutritive agents in promoting nutrition."

REPORT OF THE ACADÉMIE DE MÉDECIN OF FRANCE.

Apollinaris

"THE QUEEN OF TABLE WATERS."

"The results of the recent investigation
"in Paris and the Report of the Académ
"de Médecine of France have place
"Apollinaris Water at the head of all t
"waters examined for purity and freed
"from disease germs."

THE PASTEUR GERM FILTER

(BOUGIE CHAMBERLAND).

The only Filter proved to afford Protection against Water-borne Disease.

This statement is made on the results officially recorded of the use of over 200,000 since 1888, which are confirmed by all Laboratory experiments. A précis of the evidence will be forwarded on application.

Made to give any required supply either with or without pressure.

THE EQUIFEX DISINFECTION APPLIANCES.

(GENESTE-HERSCHER, &c.. PATENTS).

STEAM STOVES.—The only stoves complying with the Recommendations of the International Sanitary Congress (Budapesth, 1894). Only Medal, Sanitary Institute Congress, Liverpool, 1893; Only Highest Award wherever exhibited.

SPRAYERS.—Cost a fraction of the time and expense required in use of SO^2, render disturbance of inmates unnecessary, and disinfect with certainty. Exclusively used by the Municipality of Paris and elsewhere.

PARTICULARS OF OTHER APPLIANCES ON APPLICATION.

SOLE LICENSEES AND MAKERS:

An Address
ON
THE SOIL IN ITS RELATION TO DISEASE AND SANITATION.

Delivered before the Nottingham Medico-Chirurgical Society on Oct. 30th, 1895,

BY G. V. POORE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; PROFESSOR OF CLINICAL MEDICINE AND MEDICAL JURISPRUDENCE, UNIVERSITY COLLEGE, LONDON.

GENTLEMEN,—In dealing with the relation of the earth to disease it behoves us to move with caution, and we shall do well at the outset to admit that there is very little knowledge of the subject which can be regarded as certain. We are in the land of conjectures, surmises, and plausible hypotheses, which perhaps are leading on to certain knowledge, but it will be necessary to check the dicta of the laboratories by experience gained outside of them. Such has always been the admirable custom in this country, where the labours of the pure scientist have been checked by that truly excellent staff of workers, the medical inspectors of the Local Government Board, to whom the world at large is more deeply indebted than perhaps it is aware. Before we blame the earth for causing us harm we must be sure that the facts, or alleged facts, of the bacteriologist are supported by the experience of the practical epidemiologist. Science unchecked by practice will certainly lead us astray in the future as it has done in the past, and just as a "lie which is half a truth is ever the blackest of lies," so a new scientific fact imperfectly understood has potentialities for evil which are unbounded.

If we set aside for the present the question of malaria, which is undoubtedly primarily connected with certain soils, we have very little evidence that any other disease of practical importance is primarily connected with the soil. There appear to be two microbes which are present with tolerable constancy in the upper layers of the soil, which, when applied to a raw surface or injected hypodermically, may cause tetanus and malignant œdema; but as yet we are without any evidence that either of these diseases can be caused by drinking water which has percolated through the soil or can rise as a miasm from the soil. They concern the surgeon mainly, and from the point of view of epidemiology are unimportant.

Phthisis, or rather death from phthisis, which is not quite the same thing, is said to be more prevalent on damp soils than on dry ones, and it has further been said that the death-rate from this disease has been reduced in certain towns by sewerage. This statement is not universally accepted, and even if it be true it does not necessarily inculpate the soil because damp soils are cold, and patients with phthisis or any chronic lung trouble are very intolerant of cold and damp. It is very generally recognised that phthisis is prevalent in proportion to overcrowding, and that it is conveyed by tuberculous milk or meat seems to be certain as the result of recent experimental work. Any charge against the soil itself is as yet not proven.

Diphtheria has been said to be prevalent on certain soils, but this assertion is now discredited, and we recognise that the great cause of its spread is overcrowding. Its habitat, if it have any, outside the human body is not yet known.

Anthrax, which is due to a spore-bearing organism, can certainly be conveyed to animals browsing on grass soiled by the dung or blood of infected animals. The bacilli seem to die in the carcase of a dead animal within three days after death; and as, for spore formation, the free access of air and a temperature of 70° F. are necessary it is not likely that this goes on in the earth. Pasteur's assertion that anthrax spores may be brought to the surface by earthworms is discredited by Koch and others. Man, I believe, has never been infected with anthrax except by direct inoculation or, as in the wool-sorter, by inhaling spores from infected wool or hides. Clearly, animals should not be allowed to browse in an infected field, and such fields should, where possible, be ploughed up and converted from pasture into arable land. The danger of burying animals dead of anthrax is considered unworthy of credence by those eminent veterinary authorities, Professor Brown and Professor McFadyean, and the latter has shown that the process of putrefaction is fatal to the virulence of the tissues of the dead animal when these are inoculated into other animals or administered by the mouth.

Enteric fever and cholera bear a close resemblance to each other in their mode of spread, and they are both recognised in this country as mainly, if not entirely, water-borne diseases. Whether this be absolutely the case in the tropics I will not pause to discuss, because I am ignorant of the conditions of tropical life, but it is known that at present the water-borne theory, as against the air-borne theory, is receiving more and more support in India. That these diseases are produced in most cases by the direct infection of water by the excreta of infected patients is in Europe very generally acknowledged. The cholera epidemics of 1848, 1854, and 1866, and the more recent epidemic at Hamburg, strongly support the water-borne theory of cholera, and the enteric fever epidemics which afford similar evidence in this country have been so numerous that it is unnecessary to particularise. The spread of both these diseases seems to be favoured by conditions of filth and overcrowding, and the existence of a filthy and sodden condition of the soil has been often spoken of in connexion with them. Nevertheless, there have been very few outbreaks of enteric fever in which the fact that cesspools, sewers, or underground middens have been in direct communication with the sources of water has not been detected. If, as seems highly probable, typhoid fever may be conveyed by sewer air there is nothing improbable in the suggestion that it can be conveyed by the air of privies or middens in which fæces are allowed to putrefy. That typhoid fever poison can lurk in properly tilled ground seems very unlikely, and I am not aware that such a thing has ever been suggested. Pettenkofer's statement that epidemics of typhoid fever and cholera follow depressions of the ground water may be true for Munich, but it has not been materially supported in this country; and, in Budapest, Fodor has found that these diseases are more prevalent when the ground water is high. The variations of level in the ground water depend upon such a number of meteorological and other conditions and give rise to so many and different effects that even if Pettenkofer's statement be accepted it would not necessarily point to the earth as the natural habitat of the typhoid fever poison. Professor Lane Notter, in his summing up of this ground-water question, says:[1] "It must, however, be borne in mind that it is not the ground itself which is the cause of the disease, but the impurities in the soil which the varying level of the ground water helps to set in action." Now, no organic impurity can possibly reach the soil from the subsoil, which is purely inorganic. Any organic impurity which reaches the ground water must, therefore, come from above and is due in the vast majority of cases to our mismanagement of organic refuse. Dr. Sims Woodhead[2] says that "*the deeper layers* of the earth are frequently almost entirely free from micro-organisms, *just as is the ground water.*" Of course if the soil of a city be porous, and if there be a subterranean network of sewers interspersed with cesspools, this would (in the high probability that an average proportion of these contrivances leak) constitute a very great danger, but we must not blame the earth because we mismanage it. The earth, be it remembered, is our sole permanent source of wealth, and we must not needlessly quarrel with our bread-and-butter.

This world would not be habitable were it not for the humus with which its bare rocks are clothed. The humus is the living covering of the skeleton, and its formation has taken ages. The primitive bare rock which has been "weathered" by the changing seasons gets clothed with a growth of lichen. This thin but rough covering entangles stray particles, and thus and by its own decay affords a nidus for a stronger growth. This stronger growth, by chemical action and physical force, works further into the rock, on which the soaking rains and rending frosts have an increasing effect, and thus, partly by the disruption of the inorganic rock and partly by the increase in ever-growing quantities of vegetable decay, the humus rises

[1] Parkes' Hygiene, eighth edition, p. 10.

Digitized by Google

as it were, "on stepping-stones of its dead self" until it is able to afford footing and nourishment for the stately forest tree, and its fertility finally becomes sufficient to attract the attention of the husbandman. This humus, the loose, mainly organic covering of the rocks, is formed, as we have seen, by crumbling rocks from below and by the constant additions of dead organic matter which is deposited upon the surface. These additions of organic matter, be they in the form of dead animals, dead leaves, dung, or what not, become humified, and thus the stock of humus tends steadily to increase. The greater the stock of humus the greater the fertility, and the greater the fertility the greater will be the amount of dead organic matter to increase the stock of humus. The conversion of the dead organic matter into humus is a biological process and is caused by the animals which live in the humus and is perfected by the growth of fungi. On this account I ventured some years ago to speak of the humus as the "Living Earth," and I take it that no more important addition has ever been made to the stock of human knowledge than the recognition that the humus teems with life and that its fertility and healthiness depend entirely upon biological processes. If the humus be sterilised either by heat or antiseptics it becomes absolutely barren. It was at one time supposed that the fertility of the soil depended mainly upon the process of nitrification, whereby nitrogenous organic matter is converted into soluble nitrates which are absorbed by the roots of plants, and there can be no doubt that these nitrifying organisms are most important. The causes of the fertility of the soil are probably far more complex than we suppose, and I think it may be said that we are as yet only upon the threshold of our knowledge with regard to them.

The phenomenon of "symbiosis," or the living together of chlorophyll-bearing plants with those which have no chlorophyll in so-called symbiotic community where each partner works for its fellow's good as well as its own, is far more common than was supposed. Originally demonstrated in so-called lichens, which really consist of symbioses of fungi and algæ, it was next shown in the papilionaceous leguminosæ, whose nourishment appears to be largely dependent upon so-called bacterial nodules which grow upon their roots, and, according to my observations, more upon the superficial roots than those which run more deeply. In Oliver's edition of "Kerner's Natural History of Plants"[2] will be found an account of symbioses between fungi and big flowering plants in which "the division of labour consists in the fungus mycelium providing the green-leaved phanerogam with water and food-stuffs from the ground whilst receiving in return from its partner such organic compounds as have been produced in the green leaves." 'The union of two partners always takes place underground, the absorbent roots of the phanerogam being woven over by the filaments of a mycelium. ..... As the root grows onward the mycelium grows with it, accompanying it like a shadow. ..... The ultimate ramifications of roots of trees 100 years old and the suction roots of year-old seedlings are woven by the mycelial filaments in precisely the same manner." It is stated that many plants only flourish in symbiotic community, and in this fact lies the explanation of the readiness of some plants to grow and flourish from cuttings put in sand, or from seedlings grown in nutritive solutions, while others, in the absence of the necessary fungi encircling their roots, cannot be made to strike root or flourish in this way. When it is stated that to the latter class belong oaks, beeches, firs, willows, poplars, rhododendrons, and heaths the importance of symbiosis in this world will be readily understood. Now we know why it is that the gardener prizes leaf-mould in spite of its being comparatively poor in nitrogen as compared with guano. Leaf-mould is full of fungi, and in it the plant readily establishes its requisite symbiosis.

This great and astounding fact of symbiosis, of which we have only recently had cognisance, will serve to enforce the steadily growing opinion that the sphere of the chemist is in all living processes strictly limited. In estimating the value of artificial manures the chemist's dictum is of the greatest value, but his analysis when used to gauge the value of the living humus may be entirely misleading. The chemist has told us again and again that the quantity of nitrogen in humus and in earth-closet soil is, as compared with many artificial manures, comparatively small, and therefore the mistake has been made of regarding human fæces and the product of earth closets as of small manurial value. I believe that such a statement is most misleading, and on this point I claim to speak with no inconsiderable experience. It is known to many of you that for the past ten years I have cultivated a garden of about an acre and a quarter in extent, in which the only manure used has been the excremental and other refuse of some twenty cottages with about 120 inhabitants. In August last I invited a party of the British Medical Association to view that garden, and I think that none of my guests on that occasion will refuse to admit that the garden was as full of crops of one kind and another as a garden could well be. Dr. Voelcker, the chemist of the Royal Agricultural Society, whom I had the honour of numbering among my guests on that occasion, told me that he had never seen a piece of ground more fully stocked, and he very kindly went carefully round the garden with me to see if his experienced eye could detect any sign of sickness in the soil. I have never detected any such signs, and neither could he. The garden affords no evidence of being overdone with manure, and my belief is that it would take a great deal more. This ten years' experience has convinced me that human fæces constitute a manure of the greatest value, all analyses to the contrary notwithstanding. The probable explanation lies in the fact that the microbes extruded with the fæces are of great value in developing the fertility of the humus.

Many recent experiences in sanitation and in medicine force upon us the conclusion that the value of chemical analysis in biological questions is not final. Water which has been found to contain the bacillus of typhoid fever has passed the tests of the chemist, and there can be little doubt that in the past many samples of wholesome water have been condemned for containing the products, in the form of nitrates, of oxidised organic matter. Again, the action of toxines and antitoxins is quite beyond the reach of the chemist, and the marvellous results which have been obtained by administering thyroid extract teach us that in dietetics there is something which the chemist cannot gauge. Raw thyroid and cooked thyroid would give the same results on analysis, but how different is the physiological result! How different is the action of the carefully dried stomach of the calf in the form of rennet or pepsin as compared with a dish of tripe! These facts must force upon us the speculation that the same thing may produce very different effects according to the temperature to which it may have been artificially raised by drying under a vacuum or by cooking, and must drive us to the conclusion that although it may be advisable under certain circumstances to boil our milk or our water, it is possible that the act of cooking may change, we know not to what degree, the physiological action of the milk or water which has been thus treated. My experience tells me that the chemists are wrong when they say that human excreta are of small manurial value. Their analyses are doubtless right, but their conclusions are wrong and very dangerously misleading. In this statement I should be supported by the whole of the "Far Eastern" nations.

The ultimate manurial value of urine is doubtless very great, although when pure or nearly pure it is very deadly to herbage. The only satisfactory way of using urine as a manure is to imitate the farmer by mixing it with an absorbent material such as straw, sawdust, peat, earth, paper, cotton waste, wool waste, &c., placing it upon the surface of the ground and digging or ploughing it in.

The best evidence that the humus is alive is the fact that it breathes. The fungi which are destitute of chlorophyll absorb oxygen and give off carbonic acid, in this respect resembling animals and differing from the chlorophyll-bearing plants. The most easily obtained evidence of this is the fact that decaying refuse generates heat, a fact which is easily ascertained by using a thermometer. Thus I have at present in the garden of my cottage in the Thames Valley a heap of privet leaves intermixed with a quantity of fine twigs which give it great porosity and serve to admit a large quantity of air. On the morning of Oct. 21st the temperature of the air was 39° F., and the temperature of the heap of leaves was 57° (18° more than the air). On Oct. 22nd there was a heavy cold rain with a cold easterly wind. On the morning of Oct. 23rd the temperature of the air was 40° and the temperature of the heap of leaves was 56°. On the night of Oct. 23rd-24th there was (for the time of year) a very severe frost. My heap of leaves on the morning of the 24th was solidified on the surface by the frost, but the temperature of the interior

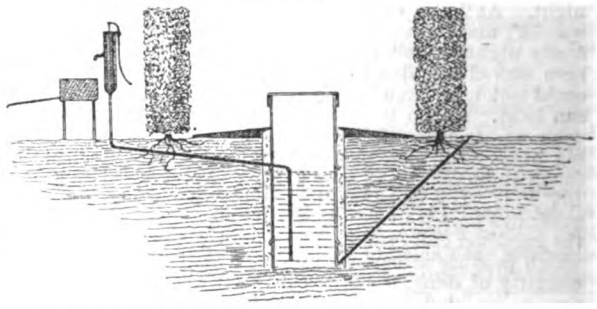
[2] Vol. i., p. 249.

Digitized by Google

was 53°, while that of the air was 30° (an increase of 23° over the air). This heap, it should be stated, is only a small heap, and would all go into a big wheelbarrow. On the morning of Oct. 24th, after taking the temperature of this heap, I turned it over with a fork, putting the frozen top in the centre and altering the position of the constituents of the heap. A quarter of an hour later the temperature of the heap was found to be 32°, and at seven in the evening it was still at freezing point, or only just above it. The night of Oct. 24th–25th was again very frosty, as many as 12° of frost having been registered at a house close by. At eight in the morning of the 25th, however, my heap of leaves showed a temperature of 40°, having risen 8° during this very cold night and being 20° above the minimum cold recorded in the night. At 7 P.M. on the 25th the temperature of the heap was 42°, and the next morning, after a third very cold and frosty night, it had risen to 45°. The rise of temperature here was clearly due to the respiration of living things and could not have been in any degree caused by absorption of sun heat. (Since the above was written autumn has come upon us, and the fallen leaves have been collected into a big heap. On Nov. 15th the temperature of this heap was found to be 62° F. and a week later (Nov. 22nd) had risen to 104° F.!) The fact that the humification of organic matter generates heat is a fact which is of enormous practical value to the gardener and farmer. The market gardens round London, which produce astounding crops and assimilate an enormous quantity of dung, are in a sense extended and mild hotbeds. One hopes that those who are advocating the burning of organic refuse will pause to think, however necessary such a process may be under certain circumstances, how great is the dispersion of energy which such a process involves and how much heat is lost which might otherwise be used for the stimulation of germination and growth in seeds and plants. One hopes also that those who would condemn as foul the humus which contains a large amount of carbonic acid will remember that this gas may only be an evidence of perfectly healthy and vigorous action. The important fact that the tillers of the soil are the most long-lived of all the labouring classes is one which must never be lost sight of.

That the humus breathes and generates an enormous quantity of carbonic acid precisely as an animal does is a fact of which the agriculturist must ever bear in mind. Many of the operations of the farm have for their object the loosening of the soil and the admission of air to enable the respiratory processes to go on. Every farmer will tell you that the earlier he can get upon the ground to hoe his turnips the better will be the crop (other things being equal), and every farmer knows the advantage of thorough tillage. If the respiration of the humus is an important fact, it becomes very important indeed not to drown it. It stands drowning no better than a man does, but, like a man, it requires a requisite amount, but not too much, of drink. There can be no doubt that the failure which is almost general of so-called sewage farming arises through the drowning of the humus; and it must be borne in mind that sewage water consists to a very considerable extent of water which has been boiled, or is hard, deep well water, and has not the valuable quality of rain water of containing some 2·5 volumes per cent. of atmospheric air dissolved in it. There can be little doubt that the great trouble to the sewage farmer is the excess of water which drowns the humus. When three or four ounces of excrement are mixed with 1200 times their weight of water they run small chance of humification, and one must fear that the difficulties of the sewage farmer (financial or agricultural, or both) must increase with the magnificence and extravagance of the water-supply of the town the sanitary interests of which the sewage farm is intended to subserve. The evil effects of too much water have come before me lately in two very striking examples. While going over the experimental farm belonging to Mr. H. C. Stephens, M.P., at Cholderton, on Salisbury Plain, this autumn (which I did in company with a large number of practical agriculturists), there were here and there noticeable in the middle of fields having a uniform quality of soil, and which had been treated in identical fashions, certain large patches over which the growth of turnips, as compared with the rest of the fields, was very defective. The explanation offered was that on these patches the animals had been folded in wet weather, that the dung had been trodden into the ground, and the soil had been hardened and consolidated by the trampling of the beasts. Under such conditions (air not being adequately admitted to the pores of the soil) the humification of the dung had been hindered and the crops stunted in consequence. This was a fact new to me, who am only an amateur agriculturist, but I may state that it was unanimously and unreservedly accepted as an adequate explanation by all the farmers present, who seemed to be perfectly familiar with the consequences of folding cattle in the wet. On the other hand, the most fertile patch of the whole farm was where the cattle had been folded for a fortnight continuously on the same spot during the severe frost of last winter, and had been fed upon food which was necessarily brought to them on that spot. The ground being as hard as iron could not be more consolidated by trampling, and with the advent of the thaw there was a general disruption of soil and dung, and humification went on rapidly in earth of which the pores had been opened by the beneficent effects of a deep frost, and which had received an amount of dung which was exceptionally great.

Another experience was a visit to a sewage farm belonging to a town in which brewing is the staple industry. This farm was large (nearly twice as big as at one time was considered necessary) and was composed of a very porous, gravelly soil in a high situation. The manager was an able man, and one felt that if success was to be obtained it was here. But the amount of water pumped on to this ground was exceptionally great, amounting at times to as much as 150 gallons per head of population per diem. The result can be imagined. The humus was drowned, and large tracts of the farm were as wet as a marsh, bore no crops, and never could be made to bear any under such conditions. As soon as it had been saturated it was ploughed up and saturated again, there being no time (let alone other considerations) to grow crops in face of the huge volumes of water which had to be dealt with. Those parts of the farm which were under cultivation grew enormous quantities of water-grass, a noxious weed, and altogether the agricultural aspects of this estate were as gloomy as could well be. As for the effluent, it was thick and turbid, and stunk like a dirty brewery. It was impossible to believe that the effluent had been rendered safe for discharge into a river, and its cost must have approached that of the beer which was sold in the adjoining town. The amount of water seemed to be the trouble here, and clearly the first duty of the municipality would be to divert directly into the river all the storm water and all the water which was used in enormous quantities for refrigerating purposes, and which, being perfectly wholesome, might go into the stream direct. A visit to the pumping-station of this municipality was most unpleasant for the nostrils, and left upon me the impression that the Local Government Board would do well to insist that all sewage committees should have a board-room at the pumping-station and another at the farm, and should be allowed to deliberate in no other place. The humification of excrement in the presence of such an overpowering amount of water is impossible, and I believe that municipalities which are now busy diverting storm water will have to go further and deal with excreta, domestic slop water, and manufacturers' effluents on different and separate systems. I confess I should like to see water-closets dealt with on an independent system by a vacuum principle such as is advocated by Shone and Liernur. Manufacturers' refuse, which is liable to contain chemicals and antiseptics, is so likely to kill the humus by poison as well as by drowning that it seems impossible to deal with it on any one system, and it is to be hoped that with the advance of chemistry it may be increasingly possible to turn manufacturing effluents to profitable account.



It is now more than ten years ago since I first deliberately drew attention to the shortcomings of modern sanitary methods, and pointed out that the safe disposal of organic refuse was a question which mainly concerned the biologist. It is a hopeful sign of the times that engineers are now recognising this fact, thanks mainly to the teaching of the Board of Health in Massachusetts. The purification of sewage is wrought by the presence of living organisms on the filters; and for the due filtration of drinking-water it is now admitted that the filtering material must have a coating of living slime. These are facts which are now all but universally admitted.

It is admitted that humus is one of the best filtering materials for water, and that water from a river full of living organisms is to a large extent freed from them by filtering through a few feet of the humus on its banks. In the past

Digitized by Google

few years Professor E. Frankland has shown that water of singular microbial purity has been obtained from the gravel beds which in places flank the Thames. Such water, one must suppose, is obtained from ground water which has fallen upon the earth, has filtered through it, and is slowly flowing towards the river. The purifying agent in these cases is mainly, one must suppose, the living humus which lies upon the surface, although the subsoil cannot be without some effect. These facts must alter our attitude towards surface wells, and must teach us what to a great extent has been admitted—that the purity of surface wells must depend more upon the mode of construction and the surroundings of the well than upon its depth. Wells are polluted by foulness which has reached the subsoil without being subjected to the purifying influence of the humus, and there are many facts which go to show that if foul water gets to the under side of the humus without going through it its purification in the subsoil is far from certain. The Lausen epidemic, the Worthing epidemic, and the pollution of the deep well sunk in the sandstone at Liverpool seem to show us that percolation through a mile of underground strata entails no certain purification, and that wells 80 ft. or 400 ft. deep are not safe if fissures allow the contents of cesspools, leaking under pressure, to trickle into them. The almost universal condemnation of surface wells and their frequent pollution are mainly due to the fact that we take our filthy and dangerous liquids through the humus in pipes, and thus ensure at great expense that it cannot be subjected to purification by it. If these underground pipes leak the mischief caused by pollution of wells may be very far-reaching. It is very probable that foul water continuously thrown on the same spot of ground may in time work its way to a well and thus pollute it. Such ground which is constantly soaked, be it remembered, is never tilled, because tillage is impossible. For ground to be tillable it is essential that reasonable breathing time should be allowed. I am not altogether sure (although I hardly dare utter such a heresy) that a properly constructed surface well in a selected situation may not prove to be one of the safest sources for water, because it can be inspected with perfect ease, and the fact of accidental leakage into it would become apparent. In this connexion it may be well to describe in full detail the well which I have sunk in my garden at Andover, a garden which is rather handsomely manured with human excreta. The well is placed in the very centre of the garden at the intersection of two paths—a broad green path and a narrower asphalted path. This situation was chosen for two reasons: (1) that it was as far as possible removed from any accidental pollution from the sewer in the street; and (2) that in the centre of the garden it would theoretically run the greatest chance of fæcal contamination from the manure used. As the well was sunk solely for experimental purposes this was essential. The garden is on a river-bank and very slightly raised above the level of the water. The well is only some 5 ft. deep, and the water stands at a level (which varies very slightly) of about 3 ft. 6 in. from the bottom. The well is lined throughout from the very bottom to a point some 15 in. above the ground with large concrete sewer-pipes 2 ft. 3 in. in diameter, and these pipes have been carefully cemented at their junctions. Outside the pipes a circle of cement concrete about 4 in. thick has been run in. It will thus be evident, the sides being perfectly protected, that no water can possibly enter this well except through the bottom, all contamination by lateral soakage through the walls being rendered impossible. The well is surrounded by an asphalte path about 3 ft. wide and slightly sloping away from it, and it is encircled by a clipped privet hedge about 5 ft. high except at those points where the circle of privet is cut by the paths. There is a closely fitting cover of oak, which has an outer casing of lead, and thus all contamination from above is prevented. The water is drawn off through a 2-in. leaden pipe which passes through the outer concrete and the concrete lining pipe, the cut passage for the pipe being carefully closed with cement. The pump is behind the privet hedge, and is provided with a sink and waste pipe which takes the overflow some twenty or thirty yards to a neighbouring stream. In this way the constant dripping of water in the neighbourhood of the well is prevented, for I am very much alive to the dangers attending a constant water-drip, which might be able in time to worm its way through soil and concrete into the well itself. I regard this question of the overflow as one of great importance which is too often neglected. Figs. 1 and 2 show this well in section and plan. The nearest point to the well upon which any manurial deposit of excreta is likely to be made is on the far side of the privet hedge, and the distance of this point from the bottom of the well is 7 ft. All water which finds its way into the well must have passed through at least 6 ft. or 7 ft. of earth, and, of course, the great bulk of the water has passed through a far greater length. Three chemical analyses of this water, one by Professor Frankland and two by Dr. Kenwood, testify to its organic purity, and three bacteriological investigations have given similar indications of purity. A bacteriological examination of the water from the river Anton and the well water, made on April 11th, 1895, gave 1133

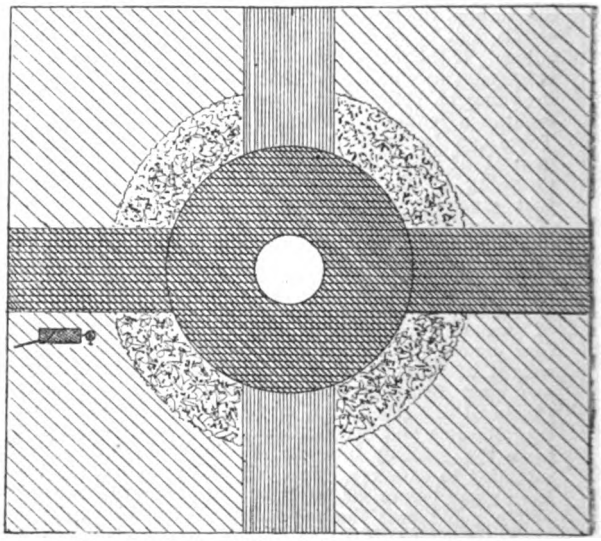


FIG. 1.

Section of well, showing concrete lining and position of pump. The diagonal line on the right of the figure is to mark the distance from the nearest garden bed to bottom of well.

growths per cubic centimetre for the river and only 7·5 for the well. Of course there may be a dangerous microbe among this small number, but, on the whole, I think the best guarantee of the purity of the water is the condition of the well, which after four years is as clean on the bottom and sides as it was the day it was made. There has been no appreciable increase of sediment on the bottom, and the pebbles are as plainly visible as they ever were. The well is for experimental purposes mainly, but water for garden use is drawn from it, and during the severe frost of last winter my gardener and some of his neighbours were entirely dependent upon it

FIG. 2.

Plan of well, showing its relation to paths and hedge.

for household purposes. I seldom go into my garden without drinking some of the water, which is clear and delicious, and my numerous guests seldom escape without drinking some also. My belief is that, as I have said, the well is a very safe one. It must be mentioned, however, that after very excessive amounts of rain, such as occurred once during the past summer, when the water came down in a perfect deluge and lay for hours in big pools upon the ground, the water in the well becomes turbid. My belief is that under these circumstances the fine sediment on the bottom

Digitized by Google

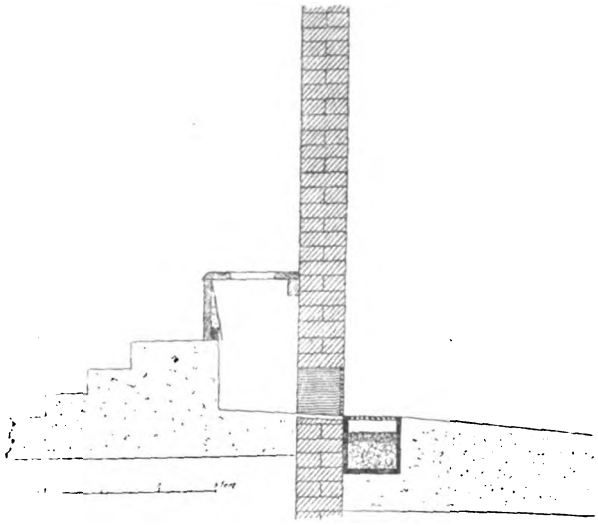
is driven upwards by the suddenly increased pressure of the water outside, and I have no reason to think that after these storms there has been any actual increase of sediment, the stones at the bottom remaining as visible as ever. I have never been able to make a bacteriological examination after one of these floods, but hope to be able to do so.

The question whether such a very shallow well becomes dangerous after a flood is a most important one. It is clearly understood that with my well there is no possibility of flood water entering at any point except through the bottom. It must be recognised that in times of flood with a drowned humus the power of purification may be lessened. On the other hand, my experience leads me to say that it is very difficult (if it be possible at all) to wash fæces out of well-tilled humus by any rain which we get in this country. Last autumn (1894), in the south of England, we had very severe floods, and I was able to note that the humification of fæces in my garden was, as a consequence, very much delayed. Fæcal matter was visible on turning up the soil for nearly three months after it had been deposited, and the masses of fæcal matter were enclosed in crusts of humus which had been rendered airless and clay-like by the excessive amount of water. This naked-eye test seemed to show that the well had not been endangered, for there were the fæces, and most certainly they had not been washed downwards. When the pores of the soil had been opened by frost the humification of the fæcal matter went forward as usual. This experience seems to enforce what I have said before—that a drowned humus cannot deal with dung. That floods may be dangerous to surface wells we all know, but it will be recognised that the conditions and circumstances of my well at Andover are distinctly different from those of the wells mentioned in the following extract, which were filled with flood water by leakage through their tops and sides.

In the Twenty-third Annual Report of the Local Government Board (1893–1894) reference is made by Dr. Thorne Thorne to certain investigations on outbreaks of typhoid fever in certain riverside populations in Yorkshire and Lincolnshire. These investigations by Dr. Bruce Low seem to prove conclusively that the fæcally polluted water of the Rye and the Trent had infected with typhoid fever a certain proportion of the inhabitants who consumed the raw river water. Dr. Thorne Thorne goes on to say: "Incidentally it transpired during the course of this inquiry that the town of Malton had an altogether exceptional history in so far as enteric fever and diarrhœa in fatal form are concerned. Situated on the Derwent, four miles below the confluence of the Rye with that river, Malton was found to derive its water-supply from the Lady Well, sunk to a depth of 14 ft. in the middle oolite rock and occupying some low-lying land close to the river bank. Into this well river water gained access as soon as the Derwent rose above a given point, the amount of river water reaching the well varying from mere leakage through holes and crevices in the banks to complete submersion of the Lady Well by the swollen stream. Gradually it had come to be noted that the outbreaks of fever and of diarrhœa followed on seasons of flood in the Derwent, a river which was referred to locally in 1890 as containing 'the sewage of all the towns and villages situated near the Rye and its numerous tributaries.'" In country places where surface wells are the only available source of water I strongly recommend that they be made on the pattern which I have been describing.

It may be well that I should describe precisely my method of dealing with excreta in my garden at Andover. My twenty cottages are provided with pails, except one which is provided with a "dry catch," and in time I hope to substitute the dry catch for the pails. It is a much better arrangement, and it is only for financial reasons that I do not effect the change forthwith. The contents of the pails and dry catch are removed every day except Sunday, and as the distance to be travelled is very slight the time occupied is not more than an hour. This daily removal is very easy and, I believe, economical; on sanitary grounds it is most advisable. The pails are provided with covers, and they are moved two at a time by one man who is provided with a milkman's yoke. The removal is thus done in ten double journeys, which vary in length from about five yards to 200 yards; perhaps an average of 100 yards, or a little more than a mile in all. With "dry catches," a properly shaped shovel, and an iron vessel on wheels for transport, the removal of the excreta from the twenty cottages to the garden could be effected in a much shorter time. In disposing of the excreta I follow nature. Under natural conditions the increase of the humus is effected solely by organic matter deposited on the surface. I therefore have the excreta merely covered by mould for decency's sake. The scavenger digs a furrow, as is done by a gardener when cultivating his land, the excreta are placed in the furrow and then covered up, and thus at one operation the land is tilled and the excreta disposed of. All foul smell is at an end the instant the excreta are covered, and in this garden, which is a pleasaunce of considerable beauty, there is never anything to offend the eye or the nose after about 7.30 in the morning. I believe that, in the absence of any evidence to the contrary, when the excreta are thus covered with earth there is an end to any danger to health. In times of exceptional frost the excreta are mixed with ashes and stored until they can be inhumed. The great importance of this superficial burial must be insisted upon. It is the top of the soil which is most full of life. As regards microbial richness the first few inches are worth all the rest. It is the top of the soil which can destroy and assimilate organic matter; the subsoil has no such power. It is a common mistake to bury deeply any organic matter which seems to us to be particularly offensive. In this way we ensure its preservation and endanger the wells. The safety of our wells is directly proportionate to the thickness of the humus, and to place organic matter below the humus is like throwing the dog's bone beneath the kennel instead of into it. The inefficiency of deep burial hardly requires to be mentioned. Bodies buried deep in the subsoil last for years, while those which are placed in the living humus are rapidly destroyed.

I should like to mention that when my well was dug there was found beneath a turf path and about three feet below the surface a large quantity of dead leaves, which had probably been deposited in a pit at some long antecedent date. They had undergone scarcely any decomposition, although they had been in that position very many years. Again, when engaged in pulling down a cottage my man unearthed an old privy some four feet below the surface. In this privy unmistakable fæcal matter was recognisable. Neither he nor I nor any of the neighbours had any knowledge of any such privy having been in use of late years, and my belief is that these recognisable excreta had been deposited at least half a century ago. Who shall say that these excreta did not still contain spores of all the ills that flesh is heir to? Under natural conditions all dead organic matter falls upon the surface of the ground, and nature is a very sure guide.



After the excreta have been superficially buried plants of the cabbage tribe are dibbled in as soon as may be. This is often done within three days, and the cabbages are sure to flourish. Seeds do not flourish with any certainty, and, although I have seen fair crops of turnips, peas, onions, &c., when the weather has been favourable, such crops are liable to fail, while cabbage as a first crop is practically sure to succeed. I could have shown you a month or so ago a spot in the Andover garden which had been sown with turnips and radishes as a first crop after manuring. The produce was Brobdignagian, but worthless except to dig into the ground. The development of green head was very great, the roots were huge and woolly. When the plan of operations which has been described (daily superficial burial followed by cabbage planting) was commenced some ten years ago many were the prophecies of failure. The practical men shook their heads and said I never should succeed that way, but that I was "bound to store the stuff in a heap to allow it to ripen before being put on the land." As a sanitarian one was naturally anxious to get the excreta below the surface of the ground as soon as possible, and I now feel confident in stating that the plan I recommend is the best from the sanitary, agricultural, and financial points of view. Sanitarily it is the best because there is no delay in the safe bestowal of the excreta; agriculturally it is best because no ammonia or other volatile body is given to the air, but all goes to enrich the land; and financially it is best because it involves moving the dung once only instead of twice, the same operation that tills the land serves to cover the dung, and while the excreta are "ripening" for other crops the farmer gets a crop of cabbage. After the cabbage crop the ground is still very rich and will grow everything or anything to which the soil and situation are suited in high perfection.

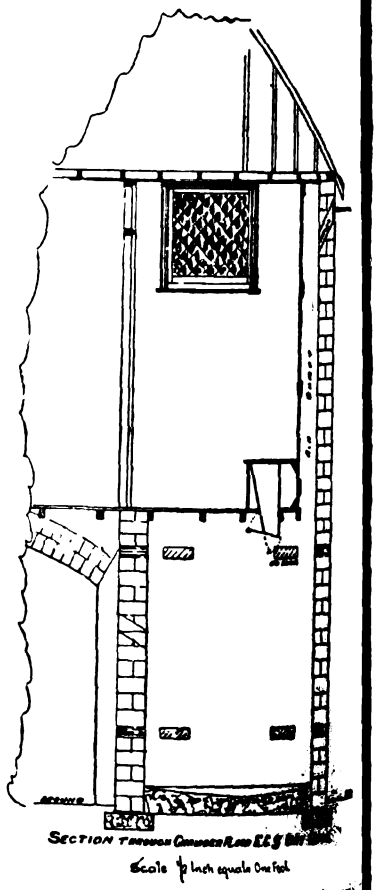
The best receptacle for excreta—far better than any form of pail—is one which imitates natural conditions and ensures that the excreta are kept above the level of the ground and are exposed to the air. Such a receptacle is the "dry catch" of which I have spoken. The privy seat is raised

Digitized by Google

on a few steps and the receptacle below is concreted, the floor being made to slope gently towards the door, which should be made of fine wire netting in order to ensure thorough aeration. The urine in part (and my experience leads me to say in very small part, because it is voided in front of the fæces, which check its downward progress) flows towards the door, and may be absorbed either by a heap of earth or by sawdust or other available absorbent contained in a specially constructed depression or gutter. This arrangement is shown in Fig. 3. In such a receptacle

FIG. 3.

Section of "dry catch" privy, with gutter filled with sawdust to absorb excess of urine.



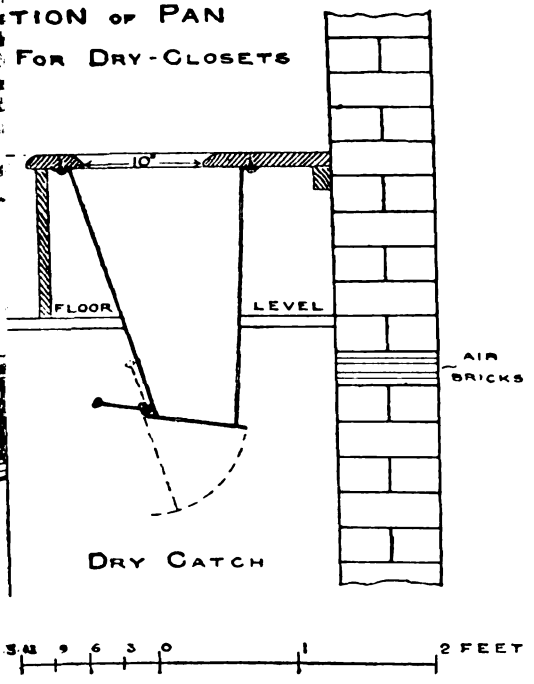
as this the humification of the fæces will go forward even though no earth be added. I had practical proof of this last summer, because the "dry catch" which I have erected was, by a mistake of the scavenger, not emptied for nearly two months, and we found that the bottom of the mass had humified and become inoffensive. No earth had been added in this case. The other figures (Figs. 4 and 5) show a specially contrived plan, the object of which is to make "dry catch" earth closets acceptable to ladies. This closet is approached from the bedroom floor of the house through a lobby having cross ventilation; the "dry catch" is on the ground floor and is provided with a door through which the soil can be removed without traffic through the house. (See Fig. 4.) The earth for this closet is also supplied from the outside through a specially contrived hopper so that the man who brings the earth cannot see, or be seen by, any chance occupant of the closet. The pan is of a shape which has carefully been considered, is screwed to the under side of the seat, and is fitted at the lower end with a flap having a somewhat heavy counterpoise. By this arrangement the excreta drop out of sight and all up-draft is prevented. The flap works in a slot and can be removed with perfect ease for purposes of occasional cleansing. (See Fig. 5.) This pan, which has worked exceedingly well for two years, was made for me by Messrs. Righton of 376, Euston-road.

To show how little annoyance may be caused under certain circumstances by excremental matters it is only necessary to appeal to the streets of London or any other large city. The amount of horse excrement and urine which are voided in the streets is prodigious, and at cab-stands the same thing goes on day after day precisely in the same spot for years together, so that the earth near there must be sodden through and through with urine; and yet how little offence there is—a certain pungency from ammonia, but no sickening, foul smell. A cab-stand is usually in very strong contrast to the urinals provided for human beings, where, in spite of a lavish supply of water, the odour is sickening and most offensive unless an attendant be provided to keep the place absolutely clean after the manner of a housemaid. Then again what is street mud? It is a collection of everything which is dropped in the street, excremental and otherwise, ground more or less by the traffic and mixed into a paste with rain water and [illegible] from the roads and vehicles. It is ugly, sticky, dirty, gives endless trouble to those who like to have their [illegible] and carriages look clean and smart; but—and this is a point to which I would call attention—it is never [illegible] offensive. It is scraped into heaps and is often left for [illegible] and practically never causes any foul smell. The [illegible] mud-heap is usually in very strong contrast to the [illegible] smell of the sewer grating alongside of it.

Simple water is by no means a perfect cleanser, [illegible] for sticky material like fæces, which we all know [illegible] its removal soap in addition to hot water and a [illegible] In a butcher's shop putrefaction is kept in check by [illegible] and fresh air, and the use of sawdust to absorb [illegible] results could not be better, and my experience has [illegible] in cow-houses, stables, piggeries, &c., the less [illegible] swilled with water the sweeter they are, provided [illegible] ample ventilation and enough absorbent material [illegible] the dung and urine to be swept up and carted away.

Our go-ahead municipalities, formed on democratic [illegible] are more ostentatious than the worst of Roman [illegible] The London County Council wished at one time [illegible] £750,000 for a *site* for its house! The central [illegible] modern municipalism are the raising of loans and the [illegible] ing of the ratepayer. It must be remembered that [illegible] is no relation between magnificence and real efficiency. [illegible] example, in a town which I sometimes visit I am [illegible] interested by a stately pageant consisting of a [illegible] veyance weighing at least half a ton and looking like [illegible] between a railway truck and a hearse. This is done [illegible]

FIG. 4.



horse weighing 15 or 16 cwt., and this horse is [illegible] two men weighing, perhaps, 12 st. apiece. Inside [illegible] are eighteen huge pails weighing 40 lb. each, and [illegible] pails are the weekly excreta of ninety people, which [illegible] if properly managed, certainly not weigh more than [illegible] 300 lb. In short, there are about 30 cwt. of [illegible] removal of at most 3 cwt. of material. This [illegible] works, it need hardly be said, at a funeral pace, and there [illegible] be no doubt that a lad with a hand-truck coming [illegible] would do the work far more rapidly, efficiently, and [illegible]

st be borne in mind that the fertility of the soil ear a certain proportion to the density of population, the ability of land to support its population ought to increase, especially if the population enjoys the s of free trade. I may perhaps best illustrate my by referring again to the visit which I paid this to the farm of Mr. H. C. Stephens, M.P. The down hich comprise this district consist of a very few f humus overlying chalk, the herbage is scanty, and lation of animals (in relation to acreage) necessarily all. One of the difficulties which the farmer has had unter in this district is the obtaining of sufficient or his stock, and perhaps the most important work Mr. Stephens has done is to sink a deep well in the This well, worked by a wind engine and provided rage reservoirs, gives a supply of water which may be d as illimitable. With good water-supply, ample nd the possibility of importing food which the neigh- railway affords, it became possible to maintain a rge number of sheep, oxen, and horses for farm and

FIG. 5.

ling purposes. The animals are all folded, and the e of their dung is returned to the soil, and the t produced by this large addition of organic matter ot fail to strike the visitor, who finds in spots e the herbage was previously so thin as to oach barrenness that he now has to wade knee- through a thick felt of grass. All over the farm the t of adding this organic matter to the soil is everywhere rent, and it is certain that the need of imported food- s for the animals must diminish in proportion to the ease of fertility of the farm. This estate on Salisbury n realises, in fact, the utopia of which I have spoken in ural Hygiene"[4]—i.e., a place where there are water- s but no sewer pipes. The indispensable water has by ful but comparatively simple engineering been brought in easy reach of the human and animal population, but organic excrements and other refuse, instead of being hed away into a neighbouring valley to poison the in- itants there, are retained upon the soil to provide extra bage, extra meat, extra work, and extra wages, with eased contentment and no loss of health. The increased ility of the soil must have the effect of counteracting erty and diminishing that charge upon the land known as Poor-rate, and, as for sanitary rates, the very essence of the gress I have been describing consists in the fact that there none to pay. When the members of the local council in this utopia have mended the roads and paid for the school they may return with a clear conscience to their own business instead of meddling with that of other people.

The fact that the potential increase of the fertility of the soil is to a certain extent proportioned to the increase of population is a political and economical fact of fundamental importance. The fertility of the soil of a country which imports millions of tons of food ought steadily to increase, and I believe that but for counteracting circumstances free trade ought to have benefited the farmer equally with all other classes of the community. If the enormous quantity of excremental and refuse matters due to free trade had been placed upon the land to increase the national stock of humus the fertility of the soil must have increased proportionately, and the fall in prices due to the competition of imported food would have been proportionately counteracted. If on the farm at Cholderton which I have been describing the well water had been used or washing all the excrement of the animals into the nearest river there could have been no increase of fertility of the soil, and the animals must have been dependent upon imported cake and other food-stuffs in a degree which would never vary, instead of, as at present, tending steadily to get less. Among the nostrums which have been suggested for the relief of agricultural distress are "light railways," but as imports and exports are apt to balance themselves one would fear that the light railway, for every truss of hay or sack of corn which it conveys to the nearest junction, will bring back a frozen carcase of meat or its equivalent. If, however, these light railways (and the existing railways) can bring the refuse of the towns on to the land to increase the agricultural capital in the form of humus, the farmers will certainly have more to sell and our need of imported food (per head of population) will tend steadily to get less. Until—if I may use the expression—we make some serious effort to leave our imported "cake" upon the land in a form in which it can be advantageously utilised, our needs for importation will never get less, and our state of scare as to the sufficiency of our navy will get steadily worse as the population increases. It is very bad policy for railways to charge exorbitant rates for the conveyance of dung, because the less dung they import the less will be the export of produce on the return journey. It is impossible to doubt that the man who increases the fertility of the soil of a country deserves well of that country and should be encouraged by the State and his fellow countrymen. Professor Otis Mason of Washington has gone so far as to say: "The form of law which does not *decrease* the amount of taxation proportionally to the yield per acre is not in the line of progress." And again: "Any law which punishes a man with taxation for preventing waste, recuperating worn acres, or developing the latent resources of nature is wicked." There can be no doubt that taxation presses very hardly upon agriculturists, especially those whose land happens to be within the boundary of a "progressive" corporation. A friend who farms 200 acres of land (of which fifteen are grass) in the Thames Valley has been good enough to show me his receipts for taxes for the year 1892, from which it appears that he and his landlord pay between them more than £300 a year in imperial and local taxes. This is due to the fact that he is under the heel of a "progressive" board, which, finding it can borrow money at 3 per cent., is making full use of its powers and is fast converting a pretty village into something scarcely distinguishable from Houndsditch.

We may now profitably turn to the consideration of malaria, a disease which is undoubtedly connected with the soil and which has its habitat in the soil of certain places. Malaria requires for its development decaying organic matter, a high or moderately high temperature, and usually an excess of moisture. Tropical marshes are the elected seats of malaria, but not the exclusive seats, for it is known that certain rocks and arid plains, as well as the sandy estuaries of rivers, are liable to be malarious. The one thing which all, or almost all, malarious districts have in common is the fact that they are barren, or nearly so, uncultivated, and in many cases uncultivable. Malaria is rare in England, but once it was common, and we must not forget that James I. and Cromwell are both of them said to have been victims of this disease, which was rife in London in their time, especially in the Essex marshes and on the south side of the Thames, in Lambeth Marsh and the adjoining districts. An undrained country is uncultivable, and it has been found that drainage followed by cultivation has in this country enormously lessened the amount of malarious disease.

[4] Essays on Rural Hygiene, second edition. Longmans, 1894.

Digitized by Google

Cultivation of land finishes the work begun by artificial drainage. The soil is dried and aerated by tillage, and the organic matter, when the humus is no longer drowned, is oxidised and goes to nourish plants and trees which effect an upward drainage no less important than the downward drainage, while the oxygen exhaled by the green leaves cannot but benefit the air of the locality. If we wish to keep clear of malaria in this country we must till the soil and so nourish the humus that its produce may be sufficiently valuable to bear the expense of any artificial drainage which it may be necessary to maintain. If the land of this country goes out of cultivation, as in places it seems to be doing, I see no reason why we or our successors should not witness a recrudescence of malarious disease in localities which are prone to develop it.

It will not be unprofitable in this connexion to consider the history of the Roman Campagna. It is generally admitted that the Roman Campagna was not always the desolate waste which it ultimately became. It was prone to malaria, doubtless, but this was kept in check by the large farming population. It is not conceivable that in days when locomotion was slow a city could have attained the proportions and importance of Rome if it had been situated in the middle of a sterile and malarious plain. The neglect of agriculture began in the Augustan age, when Rome was at the zenith of its power, and it is worthy of note that Mæcenas is credited with having incited Virgil to write the "Georgics" in order to direct, by this fascinating method, the attention of the Roman people to the neglected joys of agriculture. With the acquisition of fertile districts in Africa and elsewhere, not only did the need for home-grown commodities decrease, but it is probable that the profits of home farming decreased also. Corn was imported in enormous quantities, while the expenses connected with the defence of the Empire led to such a merciless taxation of the landholder that in self-defence he was obliged to allow his land to go out of cultivation, and thus escape from the brutal exactions of the tax-gatherer. According to Gibbon, within sixty years of the death of Constantine 320,000 acres of the district of Campania had become barren. Further, there can be no doubt that the Cloaca Maxima and other cloacæ sent to the Tiber much, if not all, of the organic refuse which should have been returned to the land. Finally, there can be little doubt that the extravagant water-supply of ancient Rome must have had the effect of causing neglect of local wells, and as the water of the aqueducts was supplied to places in the Campagna as well as to Rome itself, the discontinuance of pumping must have helped to leave moisture in the soil at the same time that an extra supply from a distance was giving an additional quantity to it. As these great works of engineering did away with the necessity of manual labour, and as the barren land stood in no need of husbandmen, it is not to be wondered at that the problem of the unemployed grew urgent in Rome. We hear that in the later days of the Empire the masses congregated at the baths or waited whole days at the doors of the amphitheatre while they were fed with doles of bread or corn supplied from the public granaries. With a dense idle population and with barren and unwholesome surroundings the amenities of Rome as an imperial residence declined, and one is not surprised to find that Diocletian seldom visited it, and one cannot but think that the social and sanitary conditions of the capital were among the causes which led Constantine to abandon it in favour of his new city on the Bosphorus. Finally, one is not surprised to hear that when Alaric took the city in the beginning of the fifth century he did so, not by direct assault, but by seizing the huge granaries and magazines at the Port of Ostia, and then offering to the unhappy Romans the choice of surrender or starvation. We are often asked to admire the Roman aqueducts, and Rome is not infrequently held up to us as a model to be copied. I fear we are copying her only too exactly, and I fear that equally with Rome we shall find out the futility of a brutal and reckless expenditure mainly directed towards the starvation of the soil and a senseless struggle with conditions imposed on us by nature. I have heard it suggested that the cultivation of the soil of England is of no importance, that our islands are destined for residential and manufacturing purposes only, and that our sustenance is to depend entirely upon "big-bellied argosies" bearing all the treasures of more fertile climes. But the cultivation of the soil and the nurturing of the humus have important bearings upon questions other than food-supply, and if we continue to starve the humus and to encourage filth beneath it instead of upon it I fear that the ... living in this country is likely to increase, while the ... of existence will diminish.

The moral of all that I have been saying is to the ... that to nourish the humus and to till it are the ... duty of the sanitarian. This simple duty is the ... plentiful food and a good supply of wholesome ... Nature is relentless and will sooner or later destroy the ... neglect to follow her inexorable laws. We used to say ... "the weakest" (morally, physically, and mentally) ... go to the wall." Now we use the expression "survival ... fittest" to express the same idea. Nature does not ... but man, in his commendable efforts towards philanthropy ... endeavours to relent, and hence the principle ... much modern sanitary work is the attempt to bring ... survival of the unfittest. If I may judge from the criticisms ... to which at one time and another the ideas which I have put ... forward have been subjected, I may conclude that ... principles advocated are considered right, but that the ... classes of our population are not to be trusted to ... to any extent the wholesomeness of their homes. They ... we are all asked to come down to the level of the ... and most careless, and our sanitary methods (in what ... is too much of Hercules and too little of Minerva ... admit of any encouragement being given to those ... within a municipal boundary who may be so circumstanced ... that they can adopt the principles I have advocated. ... we must all be tarred with the same brush, and no ... is given to those who refuse to allow the municipality ... to be put to the trouble and expense of robbing them of ... which they find invaluable on their own land. In Hackney ... have spent a considerable sum of money in freeing ... from some pollution and saving trouble to the town. Personally, I have improved the value of a house, and, of course, ... rates of that house have been raised. Such a fact is an ... effectual check upon the vast majority of those who ... wish to imitate what they may approve of in principle. ... feel assured that no real advance in sanitation will be ... until there is an equitable adjustment of sanitary rates. ... we have the right, if we desire it, to pay for water by ... That water should be paid for according to rateable ... and that the rating authority and the water authority ... be identical seems to me to be an arrangement which ... ratepayer will possibly find irksome. The greatest of ... troubles in the present day is overcrowding, and this ... is greatly fostered by our methods of sanitation. Are we ... find responsible persons suggesting that open space ... be taxed at "site value," while at the same time we are ... willing to spend any amount of millions in bringing ... from Wales because they think that eventually a ... dangerously dense population will have a density ... as great. We shall some day recognise the ... of fighting against nature. It is the engineer's boast ... overcome natural obstacles, and we of the medical profession ... cannot but have the greatest admiration for the ... tinguished members of that sister profession who, ... skill and daring, has in countless ways assisted the ... ment of our commerce and manufactures. They have ... "expelled nature with a pitchfork," but it behoves us ... remember the rest of the quotation. We must discriminate ... also between brilliancy of achievement and the end ... We all of us admire the brilliant men who made the ... Tunnel, built the *Great Eastern* steamship, and ... the luxury of the broad-gauge railway; but it is doubtful ... the original shareholders in those enterprises would ... pate in our enthusiasm. Money will accomplish ... thing in the engineering way, and it is not the engineer's ... business to consider the financial side of the question. ... have always had a shrewd suspicion that Archimedes was ... possibly less admired by the Syracusan ratepayer than ... the rest of the world, and I have often pondered what ... had he lived in these days and had made his ... request of δὸς ποῦ στῶ, the Local Government Board ... have sanctioned the issuing of a Syracusan 3 per cent. ... stock to provide the fulcrum for which he asked.

I frequently meet friends who say, "I've been reading ... article of yours about the earth," and so forth, and ... after patting one on the back and being charmingly ... plimentary, they generally end by saying, "But, after ... you know, give me a good old watercloset with a ... flush." The fascinations of this winsome apparatus ... unconquerable, and one is bound to confess that ... the apparatus be of a good pattern and well made; ...

the plumber who sets it has knowledge and a conscience; provided those who use it do not try its constitution with brickbats and old boots; provided there is not a frost; and provided there is not a drought—it does sweep out of the cockney's house material for which he has neither use nor market. All the difficulties and dangers of the watercloset are on the far side of the trap, and do not trouble the householder. I feel inclined to paraphrase the words which King Lear used to something equally fascinating and, as he found, equally treacherous:—

> "But to the syphon do the gods inherit,
> Beneath is all the fiends'. . . .
> Give me an ounce of civet, good apothecary,
> To sweeten my imagination."

As a champion of individual liberty, I would say that those who in country places wish for waterclosets should pay for them, and those who, for conscience' sake, do not pollute the rivers or starve the soil should not be taxed to pay for the misdeeds of those who do.

CASES ILLUSTRATING THE SURGERY OF THE KIDNEY.

BY J. KNOWSLEY THORNTON, M.B., C.M. EDIN.,
CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, AND TO THE NEW HOSPITAL FOR WOMEN, AND THE GROSVENOR HOSPITAL FOR WOMEN.

(*Continued from p. 1041.*)

SINCE my last communication I have, through the courtesy of Dr. W. McGowan of Maghera, Ireland, received particulars of the illness and death of Case 40 of the nephrectomies. The patient remained in excellent health for more than twelve months; then, in November, 1893, he had a very severe epileptic seizure. Other seizures followed, and though he continued his official work till April, 1895, his bodily and mental powers gradually failed, and he died this autumn after left hemiplegia of some weeks' duration, ending in coma, the epileptiform attacks having been much less frequent and severe for some time before his death. It is interesting to compare the after-history of this case with that of No. 36, already recorded, secondary deposit in the membranes of the brain being, I have no doubt, the cause of death in both cases. The seats of secondary deposit in cases of sarcoma of various abdominal organs are very interesting, and deserve more accurate observation and record than they have yet (so far as I am aware) received.

CASE 24.—This is a good example of the dangers of allowing cases of nephro-lithotomy to move about too soon, however smooth and quick the recovery has apparently been. The patient was a young woman, three years married, mother of one child twenty months old. When quite a small child she fell off a chair, breaking her collar-bone, and was laid up for a long time and ailing for longer, and during this illness she began to suffer from pain in the back and along the course of the right ureter. She had never noticed any swelling in the side. The pain came in fits and was worse after action of the bowels, and when bad was always accompanied by much irritability of the bowels. The urine was often dark and thick, but there was no very distinct evidence of hæmaturia. There was constant slight albuminuria, and oxalates were frequently present in the urine. The crystalline deposit was absent in specimens passed in the morning on getting up. I have noticed this in other cases, very markedly in No. 20. The physical examination did not help the diagnosis. I operated by the combined method on Feb. 23rd, 1893, and had much difficulty in extracting the stone. This led to so much handling of the kidney from the peritoneum that I thought it advisable to introduce a glass tube into the abdominal cavity beside the kidney, and it was in for forty-eight hours. The morning after the operation the temperature rose to 102° F., but quickly fell when the skin began to act, and she made a very smooth recovery. She was apparently quite well when she left the nursing home five weeks after the operation. The loin wound healed quickly and apparently soundly, and there was no sign of any trouble when she first began to turn about in bed or first got up. The urine before the operation contained pus and micro-organisms, so that it was a septic pyonephrosis, and there was unusual damage, facts of considerable importance in view of the after-history. She went home well early in April, and in July, during my absence from town, Mr. J. D. Malcolm opened a large perinephric abscess, putting in a rubber tube; pus and eventually urine flowed through this for some weeks. In September the wound healed, but she had some pain in the loin from time to time, but no swelling or tender spot could be found, and she was strong and well. After menstruation in November and December there was renal colic and much pus in the urine, with raised temperature, loin tenderness, and blush over the kidney. At Christmas Mr. Malcolm again saw her, and found the kidney itself greatly distended with pus, and put a tube into it through the old loin scar; she was then fitted with a renal urinal, and in March was wearing this, and was strong and well and content to let things go on as they were rather than submit to nephrectomy, which had been proposed. The amount of urine collected from the loin tube varied greatly in its proportion to that passed per urethram, from five ounces to twenty ounces being the range from the tube, the bladder urine varying from twenty to forty ounces. The history of the case after operation leads me to the conclusion that I allowed the renal wound to heal up too quickly, and that as a result the septic pyonephrosis continued and the ureter blocked and caused reopening of the renal wound and escape of pus and urine into the retro-peritoneal cellular tissue; probably some clot has become organised and partly blocked the ureter, though it is curious this should have occurred in face of the constant septic condition. The moral is, when there is septic suppuration along with calculus drain the kidney well.

CASE 25.—The patient was a married woman with several children. She had always been very active. The first symptoms of calculus came on after starting golf. There was bleeding and loin pain on slight exertion, but never an attack of renal colic. I operated by the combined method on Oct. 18th, 1893. and found at once a small angular stone in the lower part of the kidney, but had great difficulty in extracting it, as it was embedded in the substance of the kidney. I passed a rubber tube into the loin wound up to, but not into, the kidney. The calculus was an irregular and long-shaped oxalate, with very sharp points, and weighed ten grains. She made a smooth recovery and is now in good health.

CASE 26.—This is an unusually interesting case, and I must record it in a little more detail. The patient, a man aged fifty-six years, was brought to me by Dr. Kirkwood of Peterborough, who had attended him for many years, and believed him to be suffering from renal calculus. He had left the volunteers when only twenty-six years old because he passed blood in his urine, and he had long suffered severely, but had refused to have any special advice or to have anything done, until his sufferings became so severe, and his loss of health and strength so marked, that he at last consented to consult me. When he came into my room his appearance at once suggested advanced malignant disease, and on proceeding to examine the abdomen I found a hard and exquisitely tender swelling protruding low down over the bladder on the left side, which I believed to be a mass of intra-peritoneal carcinoma. I was the more inclined to this belief because this swelling was low down on the left side of the abdomen, whereas all his renal symptoms were connected with the right kidney. I think I should have advised against operation, but Dr. Kirkwood having watched the case for so many years, and being so confident that the tender body was a stone, I decided to make a small central incision and explore it with my finger. If it was a malignant growth I was prepared to advise against further interference. This was done on Oct. 23rd, 1894, and on introducing my finger I found that the tender prominence was a branch of an enormous calculus in the pelvis of the right kidney. I therefore proceeded to incise the loin, and with great difficulty, owing to its size and many branches, I at last extracted the main mass after breaking off most of the branches. The extraction was much aided by my being able to manipulate the stone through the distended pelvis from the peritoneum; several smaller stones were also extracted, some with facets fitting the branches. There was great loss of blood, and large masses of granulation tissue or new growth were torn away from the inside of the kidney, and a very large cystic cavity, behind and above the kidney, was opened and emptied of a quantity (two pints and a half) of brown serous fluid without any urinous odour. The kidney was greatly thickened and hardened; and when I had thoroughly cleared the pelvis I found another hard spot, which I believed

Digitized by Google

contained some small stones, but the patient was by this time in such an exhausted condition that I thought it better not to make any further search. Drainage-tubes were passed into the cyst and also into the pelvis of the kidney. His temperature in the rectum was 95·4° F. for many hours after the operation, and his pulse 120, but he soon rallied; the left kidney acted well, and gradually a free discharge of urine was established from the loin tubes and he began to gain strength and flesh, the drawback to a more speedy convalescence being the occasional accumulations of offensive pus in the cyst cavity, which was most difficult to keep well drained. He was up on the couch on the thirty-eighth day after operation, and went home on the fiftieth day still wearing the rubber tubes in the cystic cavity, but not in the kidney. The stones removed weighed 5½ oz. Careful observations were made for a month after the operation as to the amount of urine passed from the bladder and draining away, and the latter was found to be about one-third of the whole, but there was distinct evidence all through the case that a good deal of the urine from the right kidney passed down the ureter into the bladder. On Feb. 17th, some weeks after his return home, an accumulation took place in the cyst, owing to gradual blocking of the tube opening, and Dr. Kirkwood had to enlarge the sinus, and let out a quantity of offensive pus. He was better for a time after this, and then without any very apparent reason again began to lose flesh and strength, and died at the end of June, eight months after the operation. An examination of the kidney after death revealed the presence of extensive deposits of carcinoma, which had also spread into the tissues in the wound, and some small stones in one of the calyces, doubtless those which I thought I felt at the time of the operation. I am inclined to think that I might have obtained a longer lease of life and more comfort for this patient had I performed abdominal nephrectomy instead of nephrolithotomy; but the nephrectomy, in presence of the large cystic cavity, and with such dense and possibly malignant adhesions, would have been an exceedingly dangerous and difficult operation, and local recurrence of the carcinoma would probably have been rapid and very painful. I think that though the case could not be a cure, it is entitled to a place among the recoveries, and its ending, and the knowledge of the conditions obtained after death, rather add to, than detract from, its success as a surgical procedure. It is remarkable that with such extensive cancerous deposit in an important organ the patient should have looked so well, and gained so much flesh and strength, as he did on more than one occasion after the operation—i.e., so long as the cyst cavity could be kept free from accumulation.

CASE 27.—As not infrequently happens in surgery, this case is remarkably like the preceding one in many points. The patient was a male aged sixty years who had suffered from gout and had been a great whisky drinker, taking about half a bottle daily for a long time, and had lived a very quiet, sedentary life. There was a marked history of malignant disease in the family. In 1879 the patient had had cystitis and had been under the care of Sir Henry Thompson. Since this attack he had not been conscious of any bladder or kidney trouble, excepting that he was always obliged to get up once or twice in the night to pass urine. It had always been clear till a few weeks before I saw him, when it began to be muddy and there was a good deal of mucus in it, but never any blood at any time. He had been getting deaf for some time and since his illness had become almost stone-deaf; he was also when I saw him much emaciated, with a dry, wrinkled, and somewhat yellow parchment-like skin. He was suffering a great deal of pain in the right side, and could only lie on his back. In the situation of the right kidney there was a large fixed and tender swelling which seemed to me to be probably malignant, but I deferred a definite opinion till I had examined the urine, which I found to be heavily loaded with pus, and I therefore advised an exploration of the kidney. He bore the journey up to town from his home in the country well, but in the night after arrival he had a severe rigor, his temperature rising to 105·4° and then rapidly falling to 95·0°. I operated the following day, and found on uncovering the swelling an extensive diffused blush over it with marked increase in its size. I made an incision into it just below the last rib and found a large abscess burrowing among the muscles with great ragged cavities and very offensive fæcal-smelling pus. I found in one place a hard body which I have no doubt was a small kidney, but needling only gave the impression of dense inflamed tissue, so I left it alone, proceeding to break [illegible] the septa and to thoroughly explore the cavity, I [illegible] a small calculus bedded in caseous material, and [illegible] in about the situation of the renal end of the right ure[illegible] it was firmly embedded, and when extracted was [illegible] to be deeply grooved all round, as stones partly in [illegible] pelvis and partly in the ureter so often are. There [illegible] small opening through the cavity in which the stone lay [illegible] a sound passed through this into a great pus cavity [illegible] of the kidney. This opening I dilated and passed a [illegible] tube into the cavity. Having well washed out the [illegible] cavity with injections of warm corrosive sublimate [illegible] (1 in 1000) and removed large masses of caseous [illegible] with a scoop, I put tubes into the various pockets. I [illegible] use any ligatures or sutures. He bore the operation [illegible] better than I expected, and it soon became evident [illegible] the bladder urine and from the flow from the tubes [illegible] pelvis of the kidney or ureter had been opened. Unfortunately, it also became apparent that there was a [illegible] communication with the bowel, and this, instead of [illegible] as the abscess cavity closed up and the urinary [illegible] decreased, became evidently larger with such offensive discharge that I came to the conclusion that it was a [illegible] case like the last, the calculous irritation having [illegible] cancerous growth. With free discharge and careful [illegible] he improved for a time, but the discharge became [illegible] more offensive, he suddenly developed symptoms of [illegible] absorption rather less than three weeks after the [illegible] tion, and died very quickly with acute pneumonic [illegible] ptoms. I did not obtain a post-mortem examination. [illegible] remarkable feature in this case is the very [illegible] peri-nephric suppuration with such very slight [illegible] Only very shortly before I saw him he had been staying [illegible] his brother, who thought him very bright and well. [illegible] there must have been a rapid outbreak of carcinoma [illegible] the stone, and that ulceration and breaking down occurred after the operation and rapidly enlarged the opening [illegible] bowel. Such cases as these last two and No. 2[illegible] emphasise the importance of quickly getting rid [illegible] calculus when it is diagnosed, especially in cases [illegible] there is any reason to fear the appearance of malignant disease.

CASE 28.—This case I have already more than once [illegible] to, in which I performed Abernethy's operation for [illegible] iliac artery in order to reach two small calculi which [illegible] were lying in the lower part of the urethra. I had [illegible] performed the operation before, but found it very striking [illegible] ease with which the peritoneum and its contents [illegible] safely pushed aside without fear of injury being [illegible] and the extent to which the whole pelvis is open to exploration shows that this operation may be very useful in [illegible] cases. I shall have shortly to record one fatal case [illegible] on long ago in which, I think, this operation would [illegible] saved the patient's life.

CASE 29.—A married woman aged forty-eight, the [illegible] of several children, a fine, robust-looking woman, [illegible] strong predisposition to gout, and suffering at times [illegible] gouty eczema, had been seeing me from time to time [illegible] her own medical attendant for several years complaining [illegible] deep-seated pain in the region of the left kidney. I [illegible] first leaned to the view that it was a case of calculus [illegible] the examination of the urine often repeated always [illegible] negative results and there was nothing to make a diagnosis at all positive. Visits to Contrexéville failed to relieve [illegible] at last it was decided that I should explore the kidney [illegible] and I then found—what had never been suspected or detected—a very mobile and displaced left kidney, [illegible] stone in it. On proceeding to examine the right [illegible] I was surprised to find a small angular stone [illegible] pelvis. The question now arose whether I should perform nephrorrhaphy or right nephrolithotomy. The stone [illegible] to me the more serious ailment, and I think I was [illegible] influenced by the hope that it might be a case of transference of pain, so I decided to deal with the calculus and leave [illegible] of the kidney for a future operation if the pain persisted. The patient made a good and quiet recovery from the [illegible] lithotomy, but with no relief to her old pain, and I have [illegible] just performed nephrorrhaphy with extreme difficulty, [illegible] to the low position of the last rib and the amount of [illegible] well-developed muscle which had to be traversed. In [illegible] first time in the performance of this operation I was obliged [illegible] turn the patient half over on to her face, and then [illegible] content myself with two sutures in place of the four I usually employ. When the patient was lying on her back the [illegible]

Digitized by Google

lay right across the abdomen on its back, so that I had great difficulty in bringing it into its proper position while I introduced the sutures. It is curious that with the many examinations I made I should never have detected the mobility of this kidney. The patient was, however, of large build, stout and muscular, and the kidney a decidedly small one. I shall wait her convalescence with much anxiety to see if the pain is at last banished. It is a very nice point as to which operation it was right to perform first. I think that, on the whole, my decision at the time was the proper one, although I was inclined to doubt it just after the operation.

(To be concluded.)

SEPTIC TONSILLITIS AN ACUTE SPECIFIC DISEASE.

BY STUART A. TIDEY, M.D., M.R.C.P.LOND.

THE experience accumulated during several years of hotel practice in Switzerland has led me to the conviction that the condition under consideration—to which I have been in the habit of applying the term "septic tonsillitis" or "septic throat"—has as strong a claim to rank as an acute specific disease as have scarlet fever, measles, diphtheria, mumps, &c. I should hesitate to submit the proposition that septic tonsillitis is an acute specific disease without the support of bacteriological evidence were it not that I can call to mind no acute specific disease which has depended on bacteriology for its differentiation. Each one has been differentiated originally on clinical grounds, and bacteriology has stepped in afterwards to stamp the disease with its trade mark of essential etiology. I will define septic tonsillitis, therefore, as an acute specific disease characterised by inflammation of the tonsils and fauces due to the inoculation of a specific poison and accompanied by a general toxæmic fever the result of absorption at the seat of inoculation. With regard to etiology, individual predisposing causes are constipation and a tendency to inflammatory affections of the fauces. Children and adults seem to be equally prone to fall victims to the disease. Newcomers in an infected district are more liable to the affection than the residents are, and the disregard of sanitary arrangements exhibited by local authorities is probably due to this fact. The origin of the specific poison is, in my experience, intimately connected with defective sanitation, and more especially with inadequate flushing of sewers and the stagnation and fermentation of sewage matter. The disease occurs with the greatest frequency at and after the most crowded seasons, when the air in the vicinity of the closets is palpably offensive; moreover, the attacks arise in inverse ratio to the extent of sanitary provision in individual hotels. In this connexion I would remark that on the lake of Geneva the disease receives the euphonious name of "white throat of the lake," whilst at Pontresina I have heard it spoken of as "Pontresina throat"—terms, be it observed, which serve to transfer the onus of specific etiology from the sanitary engineer to climatic influences, and which commend themselves to the public because the initial chill, which may occur on a glacier or other expedition, is regarded by them as the exciting cause and not as the first symptom of the disease, which it naturally is. I have reason to believe, moreover, that the disease is directly transferable from person to person, and that such a mode of origin is favoured by overcrowding and defective ventilation, conditions which are frequently fulfilled in the public rooms of the less spacious hotels during the season.

The symptoms of the disease are both local and general. The local symptoms consist of pain which commences at the seat of inoculation, generally one tonsil, and rapidly involves the entire fauces, causing dysphagia. The pain is frequently accompanied by a pricking and burning sensation of the soft palate. The general symptoms consist of headache, pains in the back and limbs, prostration, and constipation—the ordinary concomitants of toxic absorption. The local signs include enlargement of one or both tonsils, with infiltration of the soft palate and uvula and extension of the inflammation into the naso-pharynx. At first the fauces are uniformly bright red in colour and gelatinous in appearance, but there is rapid ulceration at the points of maximum tension of the tonsils, and the resulting ulcers form white patches of greater or less extent, sometimes involving the pillars of the fauces and soft palate. There is a copious secretion of mucus and muco-pus from the tonsils and naso-pharynx. The febrile reaction is of sudden onset. The temperature rises on the first or second day to its maximum, falls slightly for the next few days, and reaches the normal within a week, often falling on the fifth or sixth day to sub-normal. I have never known the disease to lead to any untoward result or to be followed by paralysis. The nearest allies of septic tonsillitis are scarlet fever and diphtheria. From the former it is distinguished by absence of rash and desquamation and by its more benign and rapid course. From the latter it is differentiated by its sudden onset, by the absence of false membrane or of marked toxæmic depression in spite of the severe local inflammation, and by its more rapid and benignant course and the absence of paralytic sequelæ. It is probable, however, that the statistics of diphtheria have been greatly marred in pre-bacteriological days by the inclusion of cases of septic tonsillitis which have gone to swell the tale of recoveries from the more fatal disease.

With regard to treatment, this must be both local and general, neither ceding in importance to the other, while hygienic surroundings and a nutritious dietary are essential. The speedy recovery of the patient depends in a great measure on the frequent cleansing of the fauces and naso-pharynx with antiseptic applications. If this is omitted or the patient comes late under observation there is great enlargement of the submaxillary glands, which leads to suppuration, besides prolongation of all the painful train of symptoms. I am in the habit of ordering a thorough application to the entire fauces every two or three hours, by means of a camel-hair brush, of one of the following preparations: glycerinum acidi carbolici and glycerinum acidi tannici, of each one drachm, water to one ounce; or listerine, one drachm, water to one ounce. Each application procures a free discharge of irritating mucus and results in immediate relief to the patient. The retching produced by mechanical irritation of the back of the tongue and fauces is of service in mechanically compressing the tonsils and so aiding in the expulsion of peccant matter. The glycerine stimulates a copious flow of mucus, the tannin contracts the tonsils and so promotes the same end, while the carbolic acid is anæsthetic as well as antiseptic. Listerine is a good local anæsthetic or antiseptic, but has not the same astringent and stimulating properties as have the glycerine and tannin together. It is a far more agreeable application. With regard to general treatment, early evacuation of the bowels is all-important, and I am in the habit of following it by the exhibition of a daily morning saline aperient, which secures greatly increased comfort to the patient and enables him to take iron and tonics without inconvenience. I am not partial to antipyretics of the coal tar series, but an initial dose of phenacetin in the case of a robust patient will relieve symptoms without producing marked depression. Salicylate of soda is useful where septic tonsillitis is associated with a rheumatic diathesis. Bitters, mineral acids, bark, and iron will, I think, be difficult to improve upon in the treatment of this affection, in common with other acute specific diseases, until advancing knowledge places at the physician's disposal a complete set of specific antitoxins. Then only will the importance of differential diagnosis outweigh that of expectant attention in the treatment of febrile disease.

In conclusion, I would suggest that some forms of septic pneumonia and pleurisy are manifestations of one and the same disease as septic tonsillitis. They occur under similar conditions of defective sanitation, but although almost unknown in Alpine stations where septic tonsillitis is common, they are of frequent occurrence and often lead to a rapidly fatal issue in large towns where climatic conditions favour intra-thoracic disease. I believe that staphylococci and streptococci are the predominating micro-organic forms which are common to the affection of the tonsils and to that of the lungs and pleura. The important difference in treatment is that in septic tonsillitis the disease can be attacked at the seat of inoculation, whereas in intra-thoracic disease the organism can only be sustained while it elaborates its antitoxins and marshals its leucocytes to do battle with the invading legions of inimical micro-organisms.

POST-HEMIPLEGIC PARALYSIS AGITANS.

BY GEORGE F. JOHNSTON, M.D. EDIN., M.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.

AMONG the disorders of motion following upon hemiplegia, which are generically spoken of as post-hemiplegic chorea, there is one form in which the involuntary movements in the affected limbs closely resemble the tremor of paralysis agitans and have even in some few cases been mistaken for the shaking of that disorder. Buzzard[1] has related an interesting case of this kind, alluding to the possibility of mistaking such a condition for true paralysis agitans. In most of these cases where a necropsy has been made the lesion has been found situated, in part at all events, in the posterior part of the internal capsule, involving the optic thalamus, and the hemiplegia in such cases has been, as one would expect, accompanied by hemianæsthesia of the paralysed side. But the case of which I propose to give a brief account is not of this nature. It is a true example of paralysis agitans, and the interesting point arises as to whether the onset of the tremor after the stroke was a mere coincidence, or whether the cerebral lesion and the subsequently developed shaking palsy stood to one another in the relation of cause and effect.

The patient, a man aged fifty-six years, came under my care a year ago. Nearly seven years before he had been seized with right hemiplegia. This was complete and was accompanied at first by aphasia, which passed off in a few days. The complete paralysis of the arm and leg persisted for a considerable time and was accompanied, according to the patient's account, by loss of sensation of the same side of the body. About two months after the stroke, as power began to return, the right leg commenced to shake, and a fortnight afterwards the hand and arm became affected in the same way. This shaking had continued ever since and had become gradually worse until quite recently, but the tremor had at all events not increased during the few preceding months. So far the history is suggestive of post-hemiplegic chorea rather than of paralysis agitans, but the condition of the patient when he came under observation was conclusive as to the nature of the disease. The only distinct evidence of the pre-existing hemiplegia was persisting right facial paralysis. The grasp of the right hand was so weak as not to move the index of the dynamometer, that of the left being only twenty-five. There was no more contracture in the limbs than is customary in paralysis agitans and certainly no hemianæsthesia or hemianopia. The attitude was in itself almost pathognomonic. He stood bent forward and with head somewhat depressed, both arms flexed at the elbow and carried slightly abducted from the body. The fingers were in the interosseous position, and the continuous "pill-rolling" movement of the thumb and fingers of the right hand upon one another was well marked. When sitting down the heel kept up a continuous beating upon the floor. The nature of the tremor both in the arm and leg was very characteristic. It could be controlled for a short time by strong voluntary effort. The face was typical, the upper part being quite fixed and expressionless. When told to look up he raised his eyes and elevated the brows, the head being held stiffly and scarcely thrown back at all. The voice was characteristically monotonous and somewhat high-pitched. In turning round he moved "all-of-a-piece," turning the shoulders and pelvis simultaneously instead of shoulders first and pelvis afterwards, as in health. He walked with a short, rather quick, step and had a tendency not only to propulsion and retropulsion, which were both well-marked, but also to lateropulsion, as, especially on turning, he occasionally ran off unexpectedly towards the right. Voluntary movements were performed slowly and deliberately, and he had some difficulty in rising from a chair. He was at one time extremely restless, rising up and sitting down again at short intervals and requiring a constant change of position, but of late this necessity had become less urgent. He complained of always feeling chilly—a condition not so frequently met with in these cases as that of a subjective feeling of heat. The knee-jerks could only be elicited with great difficulty by the aid of Jendrassik's method of reinforcement, and were only just noticeable when obtained, the ankle-[illegible] the right side being quite as difficult to produce as [illegible] the left. I was able to satisfy myself that this was not [illegible] to muscular rigidity. It is certainly remarkable that [illegible] should have been no evidence of degeneration of the pyramidal tracts in a case of hemiplegia severe enough to cause [illegible] loss of power in the limbs for a period of two months [illegible] the wrist-tap also produced no reflex, and there was no [illegible] tracture which could be directly ascribed to the [illegible] lesion. The amount of contracture in the arm was [illegible] such as is met with in ordinary cases of paralysis agitans. At that time, although the disease had been in existence nearly seven years, the tremor had remained almost [illegible] lateral. I say "almost," because there was very [illegible] tremor in the left hand; and on the shaking of the [illegible] side being forcibly prevented the left-sided tremor became once very apparent. In the spring of 1896 the patient had a severe attack of influenza, and since then he has [illegible] rapidly worse. The tremor is now very marked on the [illegible] side, the left leg being affected nearly as much as the right, and the movements of the left hand, though [illegible] so violent as those of the right, are nevertheless [illegible] pronounced.

This is one of the best marked cases of paralysis agitans that I have seen. The diagnosis does not depend on the tremor alone, but almost all the classical symptoms of Parkinson's disease are present, and (a very important fact from a diagnostic point of view) the tremor affects not only the originally paralysed side, but has crossed to the other. It may be objected that the hemiplegia may have been a mere coincidence in this case and that without it the paralysis agitans would have developed. In current attacks of hemiplegia do occur in this disease, as one of the original cases described by Parkinson,[2] but it is surprising that this should be the case, as paralysis agitans is a disease of long duration and chiefly occurs at the [illegible] of life when cerebral hæmorrhage is most frequent. Why, therefore, should the converse not occur and a paralysis agitans supervene accidentally in the subject of a hemiplegia? This is of course conceivable and might occur, but I do not think that in this lies the explanation in the present case. The relation between the hemiplegia and the succeeding paralysis agitans was so close, the tremor commencing as soon as slight power was regained in the limbs, and being, moreover, for seven years confined to the formerly paralysed side, that I have more difficulty in looking upon it as a coincidence than I have in accepting it as the cause of the condition. Again, it is well to remember that in those cases in which hemiplegia has occurred as an early current complication the shaking has ceased when the paralysis has been complete, and has returned with increased violence as motor power has been regained. Notwithstanding these considerations, had my case stood alone I should have been prepared to admit that we might possibly have had to deal with a coincidence. But there are several cases on record which closely correspond with that here related, and it may be well to give a short abstract of these here. In one recorded by Westphal[3] a woman aged sixty-[illegible] had a stroke, followed by left hemiplegia. There was [illegible] some loss of sensation on the paralysed side, which was [illegible] apparent when she was seen by Westphal four years afterwards, when she presented a typical picture of decided paralysis agitans, although the distribution of the tremor was somewhat unusual. The shaking had begun four years after the hemiplegia — first in the head, and spreading in a short time, first to the right arm and then to the left. The knee-jerk on the right side was much exaggerated and was absent on the left. This Westphal ascribed to a marked contracture of the quadriceps extensor. Auerbach[4] records a case which is almost the counterpart of mine. A man aged fifty years awoke one morning with left hemiplegia. There was, however, no involvement of the face and no anæsthesia, although there was a feeling of numbness in the left thigh which lasted for two years. Motor paralysis was complete for nine months, then slight ability to move the paralysed limbs gradually returned, and, coincidently with this, tremor began in the left arm. In a few months the left leg became affected. About eight years after wards the shaking extended to the right arm and shortly afterwards to the right leg. When Auerbach saw the patient ten years after the hemiplegic attack the [illegible]

nder lip had just become involved in the tremor. symptoms, marking the case out clearly as one of sis agitans, were present. These were, briefly, pro- erspirations, characteristic position, restlessness neces- g getting up and sitting down again every few minutes, nd expressionless aspect of the face, power of control movements for a very short time by a strong effort of ll, and stiffness of the muscles at the back of the neck narked hindrance to both passive and active bending f the head. It is needless to say that the character of emor was typical. The patellar reflex was present on ides, that on the left being more marked than that on ht. Grasset[5] also briefly records a case of what he calls iparalysis agitans post-hémiplégique," in which there emor at rest in the affected side, sensation of heat, and ering" of the head and neck. This is, however, not a l case, and no indication is given as to the period had elapsed between the onset of the hemiplegia and me of the patient's coming under Grasset's observation. ding this case as doubtful, we have here three cases, ding my own, in which true paralysis agitans super- immediately upon (presumably) cerebral hæmorrhage, this renders the acceptation of a theory of co- ence infinitely more difficult. We seem to be d to the conclusion that the cerebral lesion stood causal relation to the subsequent phenomena. ing, then, that these are true cases of paralysis agitans, hat the hemiplegia acted as the immediate cause of the opment of the malady, are we justified in concluding the tremor and other symptoms were due to the ana- al site of the lesion? Auerbach answers this question e affirmative, arguing analogically from those cases dy referred to in which post-hemiplegic tremor resem- that of paralysis agitans was found post mortem to ssociated with hæmorrhages in the optic thalamus, us caudatus, and posterior part of the internal le. But he omits to mention that in none of these was there any spread to the opposite side of ody, and in none of them were there symptoms of ysis agitans properly so called. Neither in his case nor ine, at the time when the patients came under observa- was there any hemianæsthesia, which had been present he subjects of the necropsies. He admits this to be a ulty, and suggests as the possible explanation that the n in his case may have been in the pons, and considers the close proximity of the motor tracts of both sides in situation may have accounted for the subsequent spread he tremor to the opposite side. In the absence any post-mortem anatomical evidence we can only ulate as to what is most probable, and I must ess that this explanation of Auerbach's is unsatis- ory to my mind. I think it much more likely the *rôle* played by the cerebral lesion in these cases was ly that of a determining cause in subjects already pre- osed. There are many cases on record in which the king followed immediately upon a shock of some kind, ical or emotional. Even a slight injury often seems to the part of the immediately determining cause of the or, or, at all events, it determines the part in which the iest symptoms shall manifest themselves. Thus Handfield es[6] had a case in which the right arm began to shake r the patient had been knocked down by a blow the right shoulder. Charcot[7] records several similar es. In one the tremor began in the left leg after a se to the thigh. At first occasional, this became manent, and finally extended to the other limbs, whilst er symptoms of paralysis agitans developed. In another e the tremor followed a sprain of the left ankle before the n and swelling had subsided; it began in the left foot spread to the other limbs, other symptoms being well rked. I have myself had a case in which the patient had hewhat severely strained the shoulder of the arm first cted shortly before the tremor began. But it is useless to ltiply instances of a well-known fact, and I merely mention e cases in which mental shock, such as the sudden violent th of a friend,[8] or even the loss of a five-pound note,[9] e been sufficient to start the tremor which has sub- uently proved to be that of paralysis agitans. Such comparatively slight shocks being capable of acting in this way, it is not surprising that the profound shock of a cerebral hæmorrhage, wherever its situation, should, given the necessary predisposition, bring about the same series of phenomena. And just as in an ordinary person a blow on a limb or a mental shock is not followed by these consequences, so in the ordinary cases of hemiplegia no such condition results, even in those where, from the site of the lesion, a tremor resembling that of paralysis agitans is set up. The commencement of the manifestation of the disease in the paralysed limbs also corresponds to the history of cases following external trauma, and it is not surprising that the parts controlled by the cortex of the damaged hemisphere should be first affected. I do not propose to enter here into the problem of the pathology of paralysis agitans, but merely suggest that such cases as these which follow immediately upon an internal or external trauma support the view that the essential change is a nutritional one of the higher (cortical) motor centres; for it is hard to understand why, if any of the various forms of gross organic lesion which have been described by various observers be the essential element in the production of the symptoms, they should remain inert as causes until called into play by such trifling causes as those mentioned above; whilst, on the other hand, it is quite conceivable that, given an already lowered condition of nutrition of the cortical centres, a comparatively slight cause might still further lessen their control over the lower motor centres, and thus allow of the first manifestation of the tremor. A cerebral hæmorrhage would be particularly likely to do this on the side of the brain on which it occurred, and this, I suggest, is the explanation of these cases of post-hemiplegic paralysis agitans.

CASE OF ORDINARY OBLIQUE FRACTURE OF TIBIA AND FIBULA,

COMPLICATED WITH COMMINUTED FRACTURE OF THE NECK OF THE FIBULA; EXCELLENT RECOVERY FOR FIVE WEEKS; THEN EVIDENCE OF HÆMORRHAGE AND PROBABLE INJURY TO ANTERIOR TIBIAL ARTERY; AMPUTATION OF THIGH; RECOVERY.

BY JOHN B. FRY, L.R.C.P. LOND., M.R.C.S. ENG.

A MAN aged sixty-seven years, while unloading hay from a cart, on March 2nd, 1894, stepped backward on to the loose tailboard, which tilted, bringing him to the ground with considerable violence. I found an oblique fracture of the tibia and fibula at the junction of the middle and lower thirds, with much displacement, the upper fragment of the tibia projecting nearly through the skin. There were considerable ecchymosis and bruising of the skin, but only over the seat of fracture. The man was at once sent to the Cottage Hospital, Thames Ditton, where I put the leg in Cline's splints. With the exception of a good deal of trouble caused by extravasation of blood and formation of bullæ, which left superficial sores, he apparently made an excellent recovery. The leg was placed in a water-glass bandage, and he left the hospital at the end of five weeks free from all pain and swelling and able to move about by the aid of crutches. Ten days later he complained of great pain in the upper part of the front of the leg, which, however, lasted only half an hour. On the following day, he having had another attack of pain of the same character before I saw him, I cut off the bandage and sent him to the hospital. A swelling was now noticed on the external aspect of the leg between the tibia and fibula, and slightly below the level of the tubercle of the tibia. It had a circumscribed glazed appearance, and was of the size of half an orange. The patient complained of no pain, and no pulsation could be detected, but as there was well-marked fluctuation it was thought to be a superficial abscess. On opening it pus escaped, followed by small clots, and copious bleeding occurred which could only be controlled by pressure of the femoral artery. With the assistance of Dr. Lyons and Dr. Senior I amputated the leg above the seat of the swelling. The whole of the parts were found ploughed up and macerated by effused blood. The destruction of tissue being so evident, it was thought prudent to amputate higher up; accordingly I adopted the

POST-HEMIPLEGIC PARALYSIS AGITANS.

BY GEORGE F. JOHNSTON, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.

AMONG the disorders of motion following upon hemiplegia, which are generically spoken of as post-hemiplegic chorea, there is one form in which the involuntary movements in the affected limbs closely resemble the tremor of paralysis agitans and have even in some few cases been mistaken for the shaking of that disorder. Buzzard[1] has related an interesting case of this kind, alluding to the possibility of mistaking such a condition for true paralysis agitans. In most of these cases where a necropsy has been made the lesion has been found situated, in part at all events, in the posterior part of the internal capsule, involving the optic thalamus, and the hemiplegia in such cases has been, as one would expect, accompanied by hemianæsthesia of the paralysed side. But the case of which I propose to give a brief account is not of this nature. It is a true example of paralysis agitans, and the interesting point arises as to whether the onset of the tremor after the stroke was a mere coincidence, or whether the cerebral lesion and the subsequently developed shaking palsy stood to one another in the relation of cause and effect.

The patient, a man aged fifty-six years, came under my care a year ago. Nearly seven years before he had been seized with right hemiplegia. This was complete and was accompanied at first by aphasia, which passed off in a few days. The complete paralysis of the arm and leg persisted for a considerable time and was accompanied, according to the patient's account, by loss of sensation of the same side of the body. About two months after the stroke, as power began to return, the right leg commenced to shake, and a fortnight afterwards the hand and arm became affected in the same way. This shaking had continued ever since and had become gradually worse until quite recently, but the tremor had at all events not increased during the few preceding months. So far the history is suggestive of post-hemiplegic chorea rather than of paralysis agitans, but the condition of the patient when he came under observation was conclusive as to the nature of the disease. The only distinct evidence of the pre-existing hemiplegia was persisting right facial paralysis. The grasp of the right hand was so weak as not to move the index of the dynamometer, that of the left being only twenty-five. There was no more contracture in the limbs than is customary in paralysis agitans and certainly no hemianæsthesia or hemianopia. The attitude was in itself almost pathognomonic. He stood bent forward and with head somewhat depressed, both arms flexed at the elbow and carried slightly abducted from the body. The fingers were in the interosseous position, and the continuous "pill-rolling" movement of the thumb and fingers of the right hand upon one another was well marked. When sitting down the heel kept up a continuous beating upon the floor. The nature of the tremor both in the arm and leg was very characteristic. It could be controlled for a short time by strong voluntary effort. The face was typical, the upper part being quite fixed and expressionless. When told to look up he raised his eyes and elevated the brows, the head being held stiffly and scarcely thrown back at all. The voice was characteristically monotonous and somewhat high-pitched. In turning round he moved "all-of-a-piece," turning the shoulders and pelvis simultaneously instead of shoulders first and pelvis afterwards, as in health. He walked with a short, rather quick, step and had a tendency not only to propulsion and retropulsion, which were both well-marked, but also to lateropulsion, as, especially on turning, he occasionally ran off unexpectedly towards the right. Voluntary movements were performed slowly and deliberately, and he had some difficulty in rising from a chair. He was at one time extremely restless, rising up and sitting down again at short intervals and requiring a constant change of position, but of late this necessity had become less urgent. He complained of always feeling chilly—a condition not so frequently met with in these cases as that of a subjective feeling of heat. The knee-jerks could only be elicited with great difficulty by the aid of Jendrassik's method of reinforcement, and were only just noticeable when obtained, the right side being quite as difficult to produce as the left. I was able to satisfy myself that this was due to muscular rigidity. It is certainly remarkable that should have been no evidence of degeneration of the pyr tracts in a case of hemiplegia severe enough to cau loss of power in the limbs for a period of two months the wrist-tap also produced no reflex, and there was tracture which could be directly ascribed to the lesion. The amount of contracture in the arm was such as is met with in ordinary cases of paralysis At that time, although the disease had been in existe nearly seven years, the tremor had remained alm lateral. I say "almost," because there was very tremor in the left hand; and on the shaking of the side being forcibly prevented the left-sided tremor beca once very apparent. In the spring of 1895 the patient severe attack of influenza, and since then he has rapidly worse. The tremor is now very marked on b side, the left leg being affected nearly as much right, and the movements of the left hand, though so violent as those of the right, are nevertheless pronounced.

This is one of the best marked cases of paralysis ag that I have seen. The diagnosis does not depend the tremor alone, but almost all the classical sym of Parkinson's disease are present, and (a very impo fact from a diagnostic point of view) the tremor affe not only the originally paralysed side, but has s to the other. It may be objected that the hem may have been a mere coincidence in this case and without it the paralysis agitans would have developed current attacks of hemiplegia do occur in this disease one of the original cases described by Parkinson,[2] but it surprising that this should be the case, as paralysis agi a disease of long duration and chiefly occurs at the of life when cerebral hæmorrhage is most frequent. therefore, should the converse not occur and a pa agitans supervene accidentally in the subject of a plegia? This is of course conceivable and might occur, but I do not think that in this lies the explanation the present case. The relation between the hemiplegia the succeeding paralysis agitans was so close, the commencing as soon as slight power was regained limbs, and being, moreover, for seven years confined formerly paralysed side, that I have more difficulty in upon it as a coincidence than I have in accepting it cause of the condition. Again, it is well to remember in those cases in which hemiplegia has occurred as a current complication the shaking has ceased when paralysis has been complete, and has returned with no violence as motor power has been regained. Now, these considerations, had my case stood alone I s have been prepared to admit that we might possibly had to deal with a coincidence. But there are seven on record which closely correspond with that here and it may be well to give a short abstract of these In one recorded by Westphal[3] a woman aged sixty had a stroke, followed by left hemiplegia. There was some loss of sensation on the paralysed side, which was apparent when she was seen by Westphal four years wards, when she presented a typical picture of the paralysis agitans, although the distribution of the tremor somewhat unusual. The shaking had begun four after the hemiplegia — first in the head, and spr in a short time, first to the right arm and then left. The knee-jerk on the right side was much exa and was absent on the left. This Westphal ascribed marked contracture of the quadriceps extensor. Ano records a case which is almost the counterpart of man aged fifty years awoke one morning with left plegia. There was, however, no involvement of the fac no anæsthesia, although there was a feeling of numbn the left thigh which lasted for two years. Motor pa was complete for nine months, then slight ability the paralysed limbs gradually returned, and, coincid with this, tremor began in the left arm. In a few m the left leg became affected. About eight years wards the shaking extended to the right arm and afterwards to the right leg. When Auerbach saw patient ten years after the hemiplegic attack the

and under lip had just become involved in the tremor. Other symptoms, marking the case out clearly as one of paralysis agitans, were present. These were, briefly, profuse perspirations, characteristic position, restlessness necessitating getting up and sitting down again every few minutes, fixed and expressionless aspect of the face, power of control of the movements for a very short time by a strong effort of the will, and stiffness of the muscles at the back of the neck with marked hindrance to both passive and active bending back of the head. It is needless to say that the character of the tremor was typical. The patellar reflex was present on both sides, that on the left being more marked than that on the right. Grasset[5] also briefly records a case of what he calls "hémiparalysis agitans post-hémiplégique," in which there was tremor at rest in the affected side, sensation of heat, and "soldering" of the head and neck. This is, however, not a typical case, and no indication is given as to the period which had elapsed between the onset of the hemiplegia and the time of the patient's coming under Grasset's observation. Excluding this case as doubtful, we have here three cases, including my own, in which true paralysis agitans supervened immediately upon (presumably) cerebral hæmorrhage, and this renders the acceptation of a theory of coincidence infinitely more difficult. We seem to be forced to the conclusion that the cerebral lesion stood in a causal relation to the subsequent phenomena. Granting, then, that these are true cases of paralysis agitans, and that the hemiplegia acted as the immediate cause of the development of the malady, are we justified in concluding that the tremor and other symptoms were due to the anatomical site of the lesion? Auerbach answers this question in the affirmative, arguing analogically from those cases already referred to in which post-hemiplegic tremor resembling that of paralysis agitans was found post mortem to be associated with hæmorrhages in the optic thalamus, nucleus caudatus, and posterior part of the internal capsule. But he omits to mention that in none of these cases was there any spread to the opposite side of the body, and in none of them were there symptoms of paralysis agitans properly so called. Neither in his case nor in mine, at the time when the patients came under observation, was there any hemianæsthesia, which had been present in the subjects of the necropsies. He admits this to be a difficulty, and suggests as the possible explanation that the lesion in his case may have been in the pons, and considers that the close proximity of the motor tracts of both sides in this situation may have accounted for the subsequent spread of the tremor to the opposite side. In the absence of any post-mortem anatomical evidence we can only speculate as to what is most probable, and I must confess that this explanation of Auerbach's is unsatisfactory to my mind. I think it much more likely that the *rôle* played by the cerebral lesion in these cases was simply that of a determining cause in subjects already predisposed. There are many cases on record in which the shaking followed immediately upon a shock of some kind, physical or emotional. Even a slight injury often seems to play the part of the immediately determining cause of the tremor, or, at all events, it determines the part in which the earliest symptoms shall manifest themselves. Thus Handfield Jones[6] had a case in which the right arm began to shake after the patient had been knocked down by a blow on the right shoulder. Charcot[7] records several similar cases. In one the tremor began in the left leg after a bruise to the thigh. At first occasional, this became permanent, and finally extended to the other limbs, whilst other symptoms of paralysis agitans developed. In another case the tremor followed a sprain of the left ankle before the pain and swelling had subsided; it began in the left foot and spread to the other limbs, other symptoms being well marked. I have myself had a case in which the patient had somewhat severely strained the shoulder of the arm first affected shortly before the tremor began. But it is useless to multiply instances of a well-known fact, and I merely mention here cases in which mental shock, such as the sudden violent death of a friend,[8] or even the loss of a five-pound note,[9] have been sufficient to start the tremor which has subsequently proved to be that of paralysis agitans. Such comparatively slight shocks being capable of acting in this way, it is not surprising that the profound shock of a cerebral hæmorrhage, wherever its situation, should, given the necessary predisposition, bring about the same series of phenomena. And just as in an ordinary person a blow on a limb or a mental shock is not followed by these consequences, so in the ordinary cases of hemiplegia no such condition results, even in those where, from the site of the lesion, a tremor resembling that of paralysis agitans is set up. The commencement of the manifestation of the disease in the paralysed limbs also corresponds to the history of cases following external trauma, and it is not surprising that the parts controlled by the cortex of the damaged hemisphere should be first affected. I do not propose to enter here into the problem of the pathology of paralysis agitans, but merely suggest that such cases as these which follow immediately upon an internal or external trauma support the view that the essential change is a nutritional one of the higher (cortical) motor centres; for it is hard to understand why, if any of the various forms of gross organic lesion which have been described by various observers be the essential element in the production of the symptoms, they should remain inert as causes until called into play by such trifling causes as those mentioned above; whilst, on the other hand, it is quite conceivable that, given an already lowered condition of nutrition of the cortical centres, a comparatively slight cause might still further lessen their control over the lower motor centres, and thus allow of the first manifestation of the tremor. A cerebral hæmorrhage would be particularly likely to do this on the side of the brain on which it occurred, and this, I suggest, is the explanation of these cases of post-hemiplegic paralysis agitans.

CASE OF ORDINARY OBLIQUE FRACTURE OF TIBIA AND FIBULA,

COMPLICATED WITH COMMINUTED FRACTURE OF THE NECK OF THE FIBULA; EXCELLENT RECOVERY FOR FIVE WEEKS; THEN EVIDENCE OF HÆMORRHAGE AND PROBABLE INJURY TO ANTERIOR TIBIAL ARTERY; AMPUTATION OF THIGH; RECOVERY.

BY JOHN B. FRY, L.R.C.P. LOND., M.R.C.S. ENG.

A MAN aged sixty-seven years, while unloading hay from a cart, on March 2nd, 1894, stepped backward on to the loose tailboard, which tilted, bringing him to the ground with considerable violence. I found an oblique fracture of the tibia and fibula at the junction of the middle and lower thirds, with much displacement, the upper fragment of the tibia projecting nearly through the skin. There were considerable ecchymosis and bruising of the skin, but only over the seat of fracture. The man was at once sent to the Cottage Hospital, Thames Ditton, where I put the leg in Cline's splints. With the exception of a good deal of trouble caused by extravasation of blood and formation of bullæ, which left superficial sores, he apparently made an excellent recovery. The leg was placed in a water-glass bandage, and he left the hospital at the end of five weeks free from all pain and swelling and able to move about by the aid of crutches. Ten days later he complained of great pain in the upper part of the front of the leg, which, however, lasted only half an hour. On the following day, he having had another attack of pain of the same character before I saw him, I cut off the bandage and sent him to the hospital. A swelling was now noticed on the external aspect of the leg between the tibia and fibula, and slightly below the level of the tubercle of the tibia. It had a circumscribed glazed appearance, and was of the size of half an orange. The patient complained of no pain, and no pulsation could be detected, but as there was well-marked fluctuation it was thought to be a superficial abscess. On opening it pus escaped, followed by small clots, and copious bleeding occurred which could only be controlled by pressure of the femoral artery. With the assistance of Dr. Lyons and Dr. Senior I amputated the leg above the seat of the swelling. The whole of the parts were found ploughed up and macerated by effused blood. The destruction of tissue being so evident, it was thought prudent to amputate higher up; accordingly I adopted the

Digitized by Google

circular method at the junction of the middle and lower thirds of the thigh. The greater part of the wound healed by first intention, and in a short time the whole had granulated up, and the man left the hospital on May 30th. Examination of the amputated leg revealed a severe comminuted fracture of the neck of the fibula in which there was not the slightest attempt at repair, the fragments lying loose in the macerated fibres of the surrounding muscular tissue. The posterior tibial vessels were uninjured and free from atheroma, but on following the anterior vessels it was at once seen that they were the source of the bleeding, although owing to the disorganised condition of the muscular tissue they were traced with difficulty. In close proximity to them were several small splinters from the fibula, but it was quite impossible to determine which fragment had injured the vessels. There was a large extravasation of blood in front of the interosseous membrane lying amongst the degenerated and destroyed fibres of the tibialus anticus and the extensor muscles of the toes. The hæmorrhage had also extended backwards in the muscles under the gastrocnemius and soleus, but had not destroyed the tissues to the same extent as in front. It did not extend as far as the fracture of the tibia and fibula, which was found firmly united, but had almost reached the limits of the popliteal space above.

Remarks.—The case at first appeared to be a simple one of fracture of tibia and fibula, and it was not until nearly seven weeks after the accident that any further symptoms developed. The injury at the neck of the fibula took place at the same time as the fracture below, but there may be some doubt as to whether the anterior tibial vessels were injured at the same time, or the artery perforated or ulcerated by the movements of the patient after leaving the hospital.

Esher.

THE TRANSMISSION OF DIPHTHERIA BY NON-SUFFERERS.

BY HERBERT PECK, L.R.C.P. EDIN., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH TO THE ORMSKIRK RURAL DISTRICT COUNCIL.

THE following series of cases is of interest as showing the possibility of the conveyance of the diphtheria poison by persons who do not themselves suffer from the disease.

HOUSE A.

CASE 1.—A man aged forty-five years began to be ill on Oct 4th, 1894. The case was typical and was followed by double "drop-wrist." No other person in this house suffered from sore throat.

HOUSE B.

This is half-a-mile distant from House A. There was no communication between the houses till Dec. 26th, when the occupier began to work for the preceding patient.

CASE 2.—A child aged seven years and a half had a sore-throat on or about Jan. 2nd, 1895. The case was a typical one, followed by paralysis of both legs. The patient died from cardiac syncope.

CASE 3.—A child aged four years began to be ill on Feb. 6th. This was a typical case and resulted in death from asphyxia.

CASE 4.—A child aged twelve years had a sore-throat on Feb. 16th. The case was typical and was followed by dimness of sight and strabismus. Bacteriological examination of cultures from the throat showed the presence of large numbers of diphtheria bacilli.

HOUSE C.

This farmhouse stands on a peat-moss and is one mile and a quarter distant from Houses A and B.

CASE 5.—A youth aged eighteen years, brother of the last three patients, worked here from Jan. 15th. His mother stated that he was at home for a few minutes on the days his sisters were buried, but at no other time. He himself admitted having been home on each Sunday to change his shirt, which he did in the room occupied by the patients. He stated that he did not suffer from sore-throat at any time, but bacteriological examination showed typical diphtheria bacilli in large numbers to be present in his throat. There is no history of his ever having had diphtheria.

CASE 6.—A youth aged eighteen years began to be ill on Feb. 26th. He worked on the same farm as the last youth and slept with him. He went home to House D on the 27th, being then "full of cooth" and suffering from sore-throat, and unable to work. Typical diphtheria bacilli were present in great abundance on March 15th.

HOUSE D.

This is a mile and a half distant from House C, two miles from House B, and two miles and a half from House A.

CASE 7.—The patient was a boy aged thirteen years, who slept with the last patient, his brother. He came home from chapel on March 3rd, complaining of sore-throat. On the 8th he was seen for the first time by his medical attendant, and was then dying. No bacteriological examination was made.

CASE 8.—A child aged three years, sister of the last two patients, began to be ill on March 12th. The case was a typical one, and an abundance of typical diphtheria bacilli was found on bacteriological examination.

Remarks.—House B was probably infected by the father of the family, who himself did not suffer from the disease. His son (Case 5) did not suffer from the disease, though he was proved to have its germs in his throat, but he was the means by which it was carried to House C, whence it was taken to House D.

Ormskirk, Lancashire.

ON SO-CALLED GOUTY PSORIASIS.

BY T. FREDERICK PEARSE, M.D. BRUX., F.R.C.S. ENG.

PSORIASIS occurring for the first time in or after middle life presents distinctive characters and requires different treatment to psoriasis occurring in the young. Most writers divide psoriasis into syphilitic and non-syphilitic. Leaving aside syphilitic eruptions of a scaly nature (to which the term "psoriasis" is incorrectly applied for a scaly syphilide), I wish to draw attention to some differences in the cases of what are termed true psoriasis. There are roughly two chief varieties: (1) the psoriasis of the young, and (2) the psoriasis of the gouty, This distinction was first pointed out by Liveing. The former variety is characterised by occurring generally before puberty, by attacking the extensor surface of the limbs, by the scales being numerous and thick, by the almost entire absence of itching, by the absence of any eczematous eruption or history of it, by being symmetrical, and by the effect of treatment. The latter variety never commences in childhood and rarely before middle age; there is generally a history of gout in the patient or in his family. It does not affect the extensor more than the flexor surface; the itching is considerable, the patches are thin, not very scaly, and the scales are small and easily rubbed off. The eruption is scattered irregularly over the body and may be said to show a disregard for symmetry. Moreover, it has a great tendency to be complicated with undoubted eczema, and sometimes assumes an inflammatory aspect almost passing into eczema. It is often made worse by the ordinary applications for psoriasis. These patients bear arsenic badly, and stimulating fluids and highly seasoned articles of food, as well as sugar, affect the eruption unfavourably. This form in some cases alternates with acute attacks of gout, and in others seems to be suspended by them. At times the eruption develops very rapidly, even in a night. Under "gouty" remedies it often rapidly disappears—much more rapidly than psoriasis ever does in the young. The treatment most successful is the free use of liquor potassæ internally, with perhaps the addition of quinine. The addition of colchicum, however, is sometimes of great service. These patients require the ordinary routine and dietary for gout. They generally require to drink more water, and alkaline waters taken freely are especially to be advised. As the skin acts feebly in many gouty persons, bathing frequently is desirable, and warm baths may be recommended. The diet should be plain, and fish or white meat should be preferred to beef or mutton. Plenty of fruit and vegetables are desirable, but the more complete the avoidance of wine, beer, or spirits the better. Clinically, this variety is closely allied to dry eczema. Its appearance is similar and the itching in both cases is marked. Contrary to true psoriasis, it is not symmetrical and does not attack the same parts. What is its pathology? Is it a true psoriasis occurring in the gouty and modified in its clinical characters by the gouty state, or does gout have a psoriasis-like eruption

Digitized by Google

as one of its manifestations? I believe the latter is the correct supposition. The facts that the eruption in these cases occurs for the first time late in life, that it has not the same clinical characters as the psoriasis of the young—the true psoriasis—and that it yields to totally different treatment, incline me to classify it as a distinct disease of the skin from psoriasis. The same anatomical changes are often brought about by different ways, and the scaly eruptions resembling psoriasis must be differentiated from it. If there is a psoriasis-like eruption in a syphilitic subject, it should not be called "psoriasis," but "syphilis," and a similar kind of eruption occurring in the gouty should not be termed "gouty psoriasis," but "gout." Psoriasis as a name for a distinct disease should be reserved for that scaly eruption of the young which constituted the first variety. The underlying cause producing its external manifestations is not known. In its clinical character it varies considerably in different cases, and it may possibly before long be capable of further sub-division.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

HEREDITARY CONGENITAL NYSTAGMUS.

By F. W. BURTON-FANNING, M.B. CAMB., M.R.C.P. LOND.,
PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL AND TO THE JENNY LIND INFIRMARY FOR SICK CHILDREN, NORWICH.

THE following history was obtained from the father of a child brought to the Jenny Lind Infirmary for Sick Children, Norwich, with marked nystagmus, and I wish to record it in conjunction with the recent publications of Dr. George Dickson [1] and Dr. Angus McGillivray,[2] and that of the late Dr. Hadden.[3] The grandparents of the first generation lived to an old age and had no ocular abnormality. There were seven children as follows:—(*a*) Male, who had constant nystagmus from birth to his death, which occurred at the age of twenty-four from an accident. (*b*) Female, who was unaffected and died from poisoning aged eighteen years. (*c*) Male, in whom nystagmus remained constant all his life; on fixing his attention he also manifested head-nodding, which disappeared during repose. He died aged twenty-four years from phthisis, leaving four children. (*d*) Male, who had nystagmus at the age of forty-two years as marked as at birth. (*e*) Male, who was unaffected. (*f*) Male, who had constant nystagmus; he has had seven children. (*g*) Male, who had nystagmus in a most marked degree; head-nodding also, except during repose. He had one child. As to the third generation, C's family of three girls and one boy had no nystagmus, but one girl's head shook when excited. F's family consisted of three daughters and four sons; nystagmus was present in all the girls, though one at the age of eight years was improving. The four boys were unaffected, but all died between the ages of seventeen months and four years; two from convulsions, one from imperforate anus, and one from diarrhœa and dentition. G's boy died aged seven weeks, and I cannot ascertain if he had nystagmus. Here then we meet with oscillation of the eyes occurring in five members of a family of seven whose parents and other relatives had presented no such peculiarity. Of these five three married and had altogether twelve children, three of whom had definite nystagmus and a fourth a tendency to head-nodding. The liability of the two sexes was almost equal in this family, for, of eleven boys, five had nystagmus, and of seven girls three had it. I have had the opportunity of examining five members of this family; in all the nystagmus was horizontal only, it was slow during repose and became more rapid when the eyes were fixed on any object or when the person was excited. Their complexions were mostly dark, their vision and ophthalmoscopic appearances normal, and their general health good. My informant discovered this "jumping" of the eyes within a few hours of birth, and was convinced that the affection diminished in intensity as the child grew. To my mind this hereditary oscillation of the eyes, with or without movement of the head, seems most allied to hereditary tremor of the limbs and head.

A HEAVY FŒTUS.

By W. WOODWARD, L.R.C.P. LOND., M.R.C.S. ENG.

ON Nov. 29th, 1895, I was called to see a married woman of robust constitution, who, the midwife said, had been in strong labour for twelve hours, but "nothing seemed to shift. The waters," she added, "had come an hour previously." I found, per vaginam, the head to be high up in the first position and the os fully dilated. The patient was bearing the labour well; but as the head did not appear to move, though the pains were frequent and strong, I applied forceps. In an hour and a half the forceps were taken off, the head being now well down on the perineum. During its passage the mother had cramping pains in the legs, but these were neither more continuous nor more severe than is common in ordinary cases. The head was born in twenty minutes more without injury to the perineum. Then for about another twenty minutes the shoulders refused to move. Traction on the axilla effected nothing, so I pulled down the left arm and the child (a female) followed, but slipped out slowly, fully dilating the maternal outlet. The infant had vomited three times a fluid resembling liquor amnii and was becoming cyanosed before I interfered. It seemed, therefore, necessary to risk the perineum in order to save the infant. After delivery the latter lay flaccid, the cord feebly pulsating, but the escape of about one ounce of blood from the cut cord restored her, and her cries were comforting to hear. The rest of the labour gave no trouble. When the mother was comfortable the child was weighed. Two separate and distinct pairs of scales registered her weight as 11 lb. 10 oz. before she was washed. Both mother and child were doing well.

Wilton, Wilts.

CASE OF SLOW PULSE (BRADYCARDIA) EVIDENTLY DUE TO SIMPLE CONSTIPATION.

By M. M. BOWLAN, M.B. DURH., D.P.H. CAMB.,
MEDICAL SUPERINTENDENT OF THE WORKHOUSE INFIRMARY, ST. GEORGE'S-IN-THE-EAST.

THE interesting article by Dr. A. Morison on the Causes of Bradycardia which appeared in THE LANCET of Nov. 23rd is my excuse for submitting the following short note. A woman aged twenty-five, well nourished, was admitted to St. George's-in-the-East Infirmary on Jan. 13th, 1892, with a history of constipation and occasional vomiting after food. There was no history of alcoholism or dietetic error, and there was no history or sign of lead poisoning. There was no hernia or any sign of organic intestinal obstruction. She looked gloomy, complained of headache, and had a dirty tongue and foul breath, but all her organs appeared to be healthy. Her heart, however, though otherwise normal, was only beating at the rate of 48 per minute. She was given five grains of calomel on admission, but was not purged. On Jan. 14th the house mixture, sulphate of magnesia and senna, was given, but without effect upon the bowels. She was still sick occasionally after food. The pulse was still slow. On Jan. 16th the pulse-rate was 48 per minute. The patient was still constipated. On the 19th one ounce and a half of castor oil was administered. On the 20th the bowels acted well. A magnesia and sulphate of sodium mixture was ordered thrice daily. On the 21st the bowels were freely opened. The patient looked brighter and expressed herself as feeling better. The pulse was now 76 per minute, the patient being recumbent, and continued normal till her discharge on Feb. 3rd, since which time she has not come under my observation.

This case was regarded as due to the absorption of poisonous, effete, and fermentation products from the intestinal tract (whether ptomaines, leucomaines, or what not), and treated accordingly. There was no marked abdominal distension and very little vomiting, so that any local mechanical theory was out of the question.

COMPOUND FRACTURE OF THE NECK OF THE SCAPULA AND SIMPLE FRACTURE OF THE SHAFT OF THE HUMERUS BELOW THE INSERTION OF THE DELTOID.

BY F. A. A. HOLMDEN, M.D., M.S. EDIN.,
SURGEON-CAPTAIN, BECHUANALAND BORDER POLICE.

ON June 27th, 1895, a trooper was riding on the front of a regimental transport in N'gamiland, and when trying to step off slipped to the ground, falling on his back, the front wheel passing over the shaft of the right humerus and shoulder. I examined him a few minutes after the accident occurred, and found there was marked projection of the acromion, and a considerable interval between it and the head of the humerus. The deltoid was flattened, the limb had sunk into the axilla, and the coracoid process was movable and at a lower level than that of the opposite side. Crepitus could be produced. There was also a wound on the back opposite the shoulder-joint, which was caused by a stone in the sand. When the probe was used the injured part was found to communicate with the fractured neck of the scapula. The humerus was also fractured below the insertion of the deltoid. The following was the treatment adopted. The wound at the back of the shoulder was syringed with an antiseptic and dressed with iodoform. I applied an angular internal splint from the axilla to the wrist, fashioned so as to project a little below the elbow. The axillary end of the splint was shaped and padded so that it would principally support the anterior and posterior axillary borders, thus avoiding pressure on the vessels. Three short splints were placed on the other sides of the limb. The angular splint was now pushed well up into the axilla, and the four splints were bandaged to the limb; and then, after binding the arm to the side with a broad bandage, a sling was applied well supporting the projection of the angular splint at the elbow, as well as the forearm, which was kept midway between supination and pronation. When seen on Sept. 28th the patient had made an excellent recovery without deformity and had returned to duty.

Bechuanaland Border Police Camp, Kgontas, N'gamiland.

NOTES ON A CASE OF LYMPHADENOMA; EFFUSION INTO THE RIGHT PLEURA; PRESSURE ON THE RIGHT BRONCHUS.

BY CHARLES W. CHAPMAN, M.D. DURH., M.R.C.P. LOND.,
PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART, SOHO-SQUARE.

THE following case may be read in connexion with a very instructive one reported by Dr. H. Sainsbury in THE LANCET of Nov. 30th, 1895.

Seventeen years ago I was suddenly sent for to see a man who had great difficulty in breathing. On my arrival I found the patient very anæmic and with an anxious expression. The history was, briefly, that he had been in the Australian bush for about four years, and that his health had been failing for two years, during which latter period his glands had gradually become enlarged. He had returned to England to put himself under the care of Sir William Jenner who had, I think, only seen the patient once or twice before I was called in, and in a consultation the same evening Sir William Jenner told me there was no evidence of fluid in the chest when he examined it a few days before. On examination there was general lymphadenoma, with urgent dyspnœa, and the right chest was airless and full of fluid. It was resolved to tap the chest, which I did with a small trocar, but only about two drachms of fluid came away. On a second consultation Sir William Jenner questioned my having entered the pleural cavity, or, even if I had, that the cannula was too small. I accordingly used an abdominal trocar, but with no better result. The patient died the following day. At the post-mortem examination, not only was there pressure on the large veins sufficient to account for the effusion, but the right bronchus was so compressed as to prevent the ingress of air into the lung. Both punctures were seen to be into the pleural cavity, so the dryness of the tapping was owing to the physical conditions within the chest, which, though different from those found in Dr. Sainsbury's case, had a similar effect in not permitting withdrawal of the fluid; there was "no vent" whereby the air could enter.

CHARING-CROSS HOSPITAL.

TWO CASES OF TYPHOID FEVER, BOTH COMPLICATED BY HÆMATEMESIS, AND ONE BY HÆMORRHAGE; ONE RECOVERY; ONE DEATH.

(Under the care of Dr. GREEN and Dr. J. GALLOWAY.)

INTESTINAL hæmorrhage in the course of typhoid fever is not infrequent, but it is rather difficult to estimate the percentage of cases in which it occurs. One way of estimating it is by taking the percentage of those known to have suffered from it in a certain number of fatal cases, as was done by Hölscher, who found a history of intestinal hæmorrhage in 5 per cent. This, of course, gives but an inadequate idea of its prevalence, for many patients subsequently recover. "Hæmorrhage from the bowel in enteric fever occasionally coexists with hæmorrhage elsewhere, such as epistaxis, hæmoptysis, hæmatemesis, hæmaturia, bleeding from the gums, and purpuric spots, and then the disease has been designated 'hæmorrhagic putrid fever.'"[1] In both the present cases there was vomiting of blood, which was probably dependent on a congested condition of the mucous membrane of the stomach. For the notes of these cases we are indebted to Mr. William Escombe, house physician.

CASE 1. (*Under the care of Dr. Green.*) *Typhoid fever; hæmatemesis; hæmorrhage; relapse.*—The patient, a female aged twenty-three years, was admitted to hospital on Sept. 21st, 1895. Her temperature was 101° F. Her illness commenced with headache and pains on Sept. 10th. Her condition on admission was as follows. She was lying on her back; her cheeks were rather flushed, and her expression was somewhat vacant; she was quite conscious, and her memory was good. Her pulse was 104 and dicrotic. The tongue was furred down the centre; the tip and edges were clean. Her abdomen was somewhat distended; there were a few spots typical of typhoid fever. The spleen was easily palpable. The heart and lungs were normal. The urine was highly coloured and clear, and the specific gravity was 1014; there was a large trace of albumin. On Sept. 22nd the patient complained of pain in the left thigh. On examination some œdema of the left leg was found; the upper part of the left thigh was red and tender, and a cord could be felt in the course of the femoral vein. There was slight diarrhœa and the stools were typically "typhoid in character." The fever ran a normal course after this until Sept. 27th, when some blood was passed in the stools. On the following day, at 1 P.M., the patient had an attack of hæmatemesis; the blood was dark-coloured, but was not measured as it was vomited into the bed. This was followed one hour and a half afterwards by a second attack; the blood was of the same character as before and measured two ounces. The patient was treated with a hypodermic injection of morphia; all food was ordered to be fully peptonised, and one drachm of the saccharated solution of lime was added to each five-ounce feed. She was also ordered ice to suck. The pulse was 120, and the temperature remained high. For the next twenty-four hours the motions were black and tarry in character, but there was no more hæmatemesis. Subsultus tendinum was well-marked, and there was distinct tremor in both hands. There were also dulness and numerous rales at the base of both lungs. From now onwards the temperature fell steadily, but the patient was very weak and was kept upon hypodermic injections of liquor strychniæ, two minims every eight hours, and brandy, four ounces. Ten-grain naphthaline pills, three times in the day, were employed as an intestinal antiseptic. There was no more hæmatemesis or hæmorrhage, but for two consecutive days large erythematous patches lasting about twenty-four hours appeared

[1] Murchison: Continued Fevers, p. 527.

Digitized by Google

over the chest and abdomen. The thrombosed femoral vein cleared up with no further trouble. Unfortunately, the patient had a severe relapse lasting over twenty-four days, but during the whole of this time she had no bad symptoms and has since made an uninterrupted recovery.

CASE 2. *(Under the care of Dr. Galloway.) Typhoid fever; hæmatemesis; death.*—The patient, a man aged twenty-eight years, was admitted to hospital on Aug. 29th, 1895. His temperature was 101° F. His illness commenced with headache and shivering on Aug. 16th. The patient lay on his back; his face was flushed; the skin was hot and moist. The pupils were slightly dilated. The pulse was 104. The tongue was coated with white fur in the centre; the lips were covered with sordes. The abdomen was uniformly distended; there were spots typical of typhoid fever. The spleen could not be felt owing to muscular rigidity of the abdominal wall. There was tenderness over the right iliac fossa. The heart and lungs were normal. The specific gravity of the urine was 1012, acid, with a large trace of albumin. There was slight diarrhœa of a greenish colour, loose, and offensive; no undigested milk appeared in the stools. The illness ran a normal course until Sept. 1st, when the patient had a distinct and well-marked rigor at half-past nine in the evening; the pulse was 120 and the respiration 24. This was followed by another rigor on the following day at 4.30 P.M.; the pulse was 160 and the respiration 32. There were no physical signs of pneumonia. The diarrhœa continued and was checked by enemata of opium. The patient continued to get weaker, but took all his food well, with occasional slight retching, but no vomiting, until the 7th, when a very troublesome hiccough set in and lasted almost continuously until his death. The pulse became more frequent and running in character. On Sept. 10th vomiting commenced, and the patient brought up blood of a dark-red colour; much of the blood could not be measured, as it was in the bed, but three ounces were actually measured. He became unconscious and died on Sept. 11th.

Necropsy.—The deep ulceration was entirely in the lower end of the small intestine, none of the sloughs having separated; the upper part of the small intestine was ulcerated superficially. The mucous membrane of the stomach was much congested, and on the posterior surface at the pyloric end twenty or thirty petechial spots were visible. There was no evidence of old or recent ulceration. The œsophagus was healthy. There was no ulceration of the larynx.

ROYAL SOUTH HANTS INFIRMARY.

HISTORY OF A CASE OF A TAMARIND STONE IN THE RIGHT BRONCHUS; NECROPSY; REMARKS.

(Under the care of Dr. A. B. WADE.)

THE record of the treatment of a case of foreign body when impacted in a bronchus is always worth reading, and when there are also unusual features presented it is additionally interesting. It is unfortunate that the result in the present instance was fatal, but the case is possibly more important to the profession on account of the emphasis which is thus laid on the necessity of keeping open the tracheotomy wound until the body has been expelled. The condition of the lung, as met with at the post-mortem examination, was that usually resulting from the impaction of a foreign body in the bronchus, and it by no means follows that the child would have recovered from this even if the foreign body had been successfully expelled. Although the collection of a large number of cases gives statistics on this subject, still the prognosis must vary so much in individual cases that they can be of little practical utility. All the bodies impacted in this situation are not of the same size or shape; neither are they of the same material, varying as they have done from the steel blade of a tooth forceps to the foreign body in this case, and the size of the bronchus has varied from that of the adult downwards. Some of the substances impacted are early acted on by the secretions of the part, whilst others are affected only after a long time or not at all. For the notes of this case we are indebted to Mr. W. P. Purvis, F.R.C.S., house surgeon.

A little boy aged five, who had always been thoroughly healthy, was admitted to the Royal South Hants Infirmary, under the care of Dr. Wade, on April 23rd, 1895. A quarter of an hour before he was brought to the hospital he had been eating tamarinds, and was seized with an attack of coughing and choking, which his mother supposed to be due to a stone having stuck in his throat. On admission he had constant and spasmodic cough and a little inspiratory stridor. A large quantity of frothy mucus was secreted. Nothing could be seen or felt in the fauces or larynx. On auscultation it was found that no air was entering the right lung. On being laid down upon the bed he breathed quite easily and showed no distress. During the evening he passed a tamarind stone in a stool, but this only pointed to the fact that he had not been careful about the stones. For the benefit of those who may not recall the exact appearance of a tamarind stone, it may be remarked that, though the West Indian are not quite the same, the East Indian are of a stony hardness and a red colour. In size they vary from one-third to one-fourth of an inch in diameter. They are flat and circular, and about three-sixteenths of an inch thick. Each is enclosed in a tough fibrous husk. On April 25th no air entered the patient's right lung, and the heart was drawn over to the right side, its impulse being felt over a somewhat wide area between the sternum and the right nipple. He had very little cough. His temperature, which had been normal, suddenly ran up to 102·6° F. Under chloroform Dr. Wade performed a low tracheotomy and made search for a foreign body which was presumably impacted in the right bronchus. This might have been either the hard stone or its fibrous husk. Nothing could be felt, and the excursions of the trachea and the reflex cough when the mucous membrane was touched by instruments were very embarrassing to the operator. Inversion was also tried, but without result. A Durham's tube was inserted. On the 28th the temperature was still 100° to 102°. The wound was healthy. The heart seemed to be going back to its normal position. On the 29th the temperature was 101°. The apex-beat was in the normal situation. The patient did not seem to be quite so well. The whole of the right side of the chest was dull on percussion, and there was very loud tubular breathing all over it except at the base behind. On the 30th the silver tube was exchanged for a rubber one, and the patient was very comfortable with it. The temperature was 102·6°. On May 6th the temperature was 98° in the morning, having been 102 2° the evening before. The patient's general condition was not so good. The physical signs were unchanged except that from the front a little air seemed to enter the upper lobe of the right lung. Another attempt to remove the stone on this day was as unsuccessful as the last. No foreign body could be felt at all. Liberal brushing of the trachea with a 20 per cent. solution of cocaine failed to stop the cough reflex. On May 25th the patient seemed to be better in himself, and a little air seemed to enter the right lung. It was not quite so dull as formerly. Since the last date his temperature had been normal or subnormal in the morning, running up to 102° or 104° (105° on one occasion) every night. He had emaciated greatly, but was beginning to pick up again. On the 28th the tracheotomy tube was removed (thirty-sixth day). On the 30th the patient's weight was 2 st. 1 lb. He got up for the first time and continued to do so. On June 7th his weight was 2 st. 4½ lb. The tracheal wound was quite healed. He seemed to be much better, and his temperature did not rise so much at night. On the 13th his weight was 2 st. 4½ lb. On the evening of that day his temperature reached 104°, but he seemed to be about as well as usual, and the physical signs were unchanged. On the 14th (fifty-third day), about 2.15 A.M., he suddenly awoke from sleep, coughing and choking. Mr. Purvis was immediately summoned and lost no time in repairing to the ward. He found the patient pale and with staring eyes. The patient gave a few gasps, but no air entered his chest. By the time Mr. Purvis had reopened the old wound the patient had ceased to breathe and his heart could not be heard. Artificial respiration was performed for some little time, but without avail.

At the post-mortem examination on June 14th, at 2.30 P.M., the body was found to be somewhat wasted. The bean lay impacted just below the cricoid cartilage, filling the trachea from there down to the tracheotomy wound. The mucous membrane of the right bronchus was reddened and slightly softened, but there was no ulceration. The diameter of the tube was markedly greater than that of the left, and the stone had evidently been impacted at about the middle of its length. The right pleura was obliterated, with soft, recent adhesions. The lung was large and completely solid. On section several points of pus appeared, which were the cut ends of bronchioles, the latter being

Digitized by Google

distinctly dilated. The stone measured in its swollen state three-quarters of an inch by half an inch across. Its shell was quite soft and chipped away in places, exposing the white cotyledons and the radicle. A portion of the lung was hardened and cut into sections. What struck the eye at once was the fact that all the alveoli were collapsed. There was absolutely no exudation into them. The capillary vessels running among the clumps of alveoli were crowded with corpuscles, and there was an enormous increase of the interstitial fibrous tissue. This last fact accounts for the affected lung (although airless) being more bulky than the healthy one.

Remarks by Mr. PURVIS.—The failure of the attempts at extraction were due to the softening of the stone, which prevented it from being distinguished from the walls of the bronchus on probing, and to the violent coughing, which absolutely prevented any delicate manipulation of instruments. There was also the doubt as to whether the foreign body was the stone itself or only the soft, tough husk, which would doubtless have been soon ejected, as it would not have swollen. It was easy to realise afterwards that it would have been impossible for the seed to have travelled up through the glottis, owing to its having swollen so much. The moral clearly is that the tracheal wound should never be allowed to heal while any chance remains of the foreign body being still in the chest, and that such a seed, though it may swell and soften, does not disintegrate even after fifty-three days.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Discussion on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues, as in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, &c.

AN ordinary meeting of this society was held on Dec. 10th, Mr. HUTCHINSON, President, being in the chair.

The adjourned discussion on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues was continued by Dr. PHINEAS ABRAHAM, who introduced the subject of the Latency of Leprosy. He said that there were many facts in connexion with leprosy which bore upon the question of latency. Numerous instances had been met with in which the symptoms of that disease had not made their appearance until long and irregular periods had elapsed since the individual could have been subjected to infection, and there were many cases on record in which the symptoms appeared to have become dormant during the course of the malady or subsequently to its full development. We might thus distinguish an initial or "primary" and a "secondary" latency. The study of the subject was beset with considerable difficulty, as might be seen from the following considerations: 1. In the present state of knowledge we could not speak of any definite period of incubation for the bacillus of leprosy, for no one had yet indubitably succeeded in cultivating it, and of its life-history we knew nothing. 2. We could not clinically determine the entry of the microbe into the human body, for, as a general rule, there was observed no initial lesion or particular symptom. In a few cases there might be a history of some previous traumatism, with localised persistent inflammation or difficulty of healing; but the vast majority of patients could not point to anything of the kind or give any precise date as to when they could have contracted the malady. In point of fact, it was not yet proved that the virus of leprosy might not gain entry by the stomach or by as many different channels as the sister disease tuberculosis. 3. It was not easy to distinguish between the true latent and the incubatory periods. We might, with M. Besnier, consider that the incubatory stage only commenced when the latent spore should have found the soil and other conditions suitable for its proper growth and development, but the subjective and objective phenomena of the incubation might be slight and overlooked, and it must often be practically impossible to draw a line of demarcation between the two stages, which, nevertheless, must be theoretically admitted to exist. A period could only be regarded as one of latency (1) if there were absolutely no concomitant [illegible] or local disturbances, and (2) if the interval between [illegible] tion and the appearance of symptoms were more or less [illegible] longed and of indefinite duration. 4. From the above [illegible] siderations, and from the fact that the inhabitants [illegible] infected country might at any time be unknowingly [illegible] under conditions for contracting the disease, we [illegible] only—to be quite free from doubt—take into [illegible] those individuals who were of a leprosy-free race [illegible] who had recently come from a leprosy-free [illegible] and (2) those, natives or others, who having [illegible] in a leprous district had subsequently [illegible] the disease after removal to a country free from [illegible] The field of accurate observation was therefore [illegible] narrowed. When facts of some definiteness were [illegible] the main thing observed was the irregularity of the [illegible] between the probable time of entry of the virus and the [illegible] appearance of the usual erythematous patches and [illegible] early pathognomonic signs. Some observers gave two [illegible] years, others much longer. Instances were known of [illegible] disease appearing a few weeks after a patient had [illegible] from an unaffected to an affected district, as [illegible] related by Arning; and, on the other hand, there [illegible] many examples of a prolonged retardation, as [illegible] mentioned by Leloir, Höegh, Thin, and others. [illegible] remarkable instances of prolonged primary latency [illegible] come under Dr. Abraham's notice. The first was the well-known Whitechapel case exhibited at the Epidemiological Society in 1889. The man had gone in his youth, upwards forty years previously, on voyages to the Baltic and Mediterranean, and afterwards had been for years selling [illegible] London, and had never mixed with sailors or others from foreign parts. He declared that he had no spots or [illegible] symptoms until six years before Dr. Abraham saw him. Although difficult to prove absolutely, it was most improbable that this man could have been exposed to any new source of infection during these forty years. It was more likely that the germ had really remained somewhere quiescent in his system for a great number of years, although, perhaps, not so long as he thought, seeing that he might have overlooked, as [illegible] lepers did, the very earliest signs of the complaint. In the following two cases the facts were tolerably [illegible] An Englishman had been taken to India as an infant, brought home when ten years old. When twenty-two he married a young English girl and shortly afterwards developed spots upon him. He died a few months after [illegible] firmed nodular leper. Since his return home he had lived in a humble way in a small inland town, and had never had communication with anyone or anything from India. The young woman, now a typical case of nodular leprosy, was born in Ceylon of English parentage, and brought to England when quite a young child. She remained perfectly well for some seven years, when she had an attack of what was thought to be rheumatic fever, accompanied with profuse erythematous swellings. The family had had no communication, directly or indirectly, with the East. It must be admitted that in her case, also, the germ must have remained dormant for many years. Instances of so-called arrested or dormant leprosy, in which the symptoms remained in abeyance for a number of years, were frequently met with in asylums and leprous countries, and might be taken to illustrate the secondary latency of the disease. [illegible] in rare cases, a recrudescence did not take place, the patient might be regarded as in a condition of permanent arrest or cure. Hansen's views were referred to, and the investigations of the Cape Commission mentioned. A case of temporary arrest of early symptoms in a boy now in England was also alluded to. In such cases the microbes had for a time ceased growing and multiplying and had assumed a resting condition. Manson's hypothesis was quoted as affording a plausible explanation of the vagaries of leprosy—the periods of quiescence, its prolonged and uncertain incubation, its difficulty of inoculation, and many other points—which shortly as follows. The bacillus was the cause of leprosy, grew only in a medium existing in the bodies of [illegible] human beings, and then perhaps only intermittently. If a bacillus fell upon such a person, it grew if the medium was present or when it was produced; it grew at the expense of the material and until the latter was exhausted; it then passed into a condition powerless to resist certain [illegible] phagocytes, which incorporated it, and in which it became encysted, until fresh cultivating medium was supplied. The bacillus then became active, passed by vessels and lymphatics and established other foci; when the cultivating [illegible]

Digitized by Google

became exhausted the bacillus again became intra-cellular and passive.

Mr. J. ERNEST LANE continued the discussion, taking for his subject the Latency of Syphilis. He first alluded to the interval which might elapse between the appearance of the initial lesion and the first manifestation of constitutional infection. The minimum recorded period of this "second stage of incubation" was twelve days and the maximum 159. The latency of syphilis was next exemplified by cases in which, after the disease had apparently disappeared, it again manifested itself by the appearance of unmistakable symptoms after a lengthy period of complete immunity. While the possibilities in the direction of long latency were infinite, the duration of the period might continue for only two years. In hereditary syphilis the disease might be latent in the father, who, though apparently healthy, might infect his wife and children; or might be latent in the mother, who, having suffered from syphilis and having been presumably cured, might on marrying a healthy man produce a long series of syphilitic children. Further, Colles's law on the immunity of the mothers of syphilitic children was another example of the latency of the disease, for such mothers, though to all appearances perfectly healthy, had been proved by inoculation with syphilitic secretions to be protected from the disease. Lastly, cases of syphilis hereditaria tarda were instanced as proof that the disease might remain latent for a long time in the subjects of congenital syphilis.

(To be continued.)

MEDICAL SOCIETY OF LONDON.

The Diagnosis and Treatment of Early Cancer and Cysts of the Breast.

AN ordinary meeting of this society was held on Dec. 9th, the President, Sir JAMES CRICHTON BROWNE, being in the chair.

Mr. BRYANT read a paper on the Diagnosis and Treatment of Early Cancer and Cysts of the Breast. He said he had been induced to write it on account of a series of cases of cystic disease of the breast, most of which had been diagnosed as being cancerous tumours, having recently passed under his notice; and he was convinced that such errors of diagnosis might be diminished by care and thought. He admitted that typical examples of cancer as well as of adeno-sarcoma were usually readily recognised, and that difficulties of diagnosis, and consequently uncertainty of treatment, chiefly occurred when any or many deviations from the typical examples were met with. He divided his cases, in which difficulties of diagnosis were liable to occur, into the three following groups, the divisions being based on clinical symptoms alone. Group 1 included cases in which either in a young, middle-aged, or even old married or unmarried woman there was some enlargement or thickening of one lobe of a mammary gland, without any external evidence of wrong, either in the integument covering the affected lobe of the breast, the nipple, or lymphatic glands. Group 2 comprised cases in which there was a distinct and very evident lump, the size of a nut or walnut, shelled or unshelled, and inseparable from the breast gland, with some of the local conditions generally accepted as being indicative of a cancerous tumour, such as a flattened or retracted nipple, with or without an enlarged lymphatic axillary gland. Group 3 included cases in which in the middle-aged woman past child-bearing the breast gland feels to be generally, or in one or more of its lobes, harder than natural, coarse or knotty, the knots varying in size from small to large peas or nuts, and where there might be at times, with or without the application of pressure upon the gland, some discharge from the nipple of either a clear yellow or bloodstained fluid, or some cheesy pultaceous material, associated or otherwise with an enlargement of some lymphatic glands. He then took up each group separately and pointed out the questions which came before the surgeon with reference to diagnosis and treatment. In Group 1 the main question to decide was whether the local lump or induration was an early cancerous tumour or a cyst, or, if in any way connected with lactation, a chronic abscess. If probabilities pointed to its being cancerous in its nature he showed how important it was to have the diagnosis clear and the local disease removed; for such a measure, when undertaken at the very earliest stage of incipient infiltration, was far more likely to be followed by a permanent cure than when performed at any later stage. For this purpose he advocated in these cases an early exploratory incision as a preliminary measure to an excision of the growth and gland should the diagnosis of carcinoma be verified. He said he had followed this practice for many years and with the best results. In Group 2, in which there was a distinct tumour present and the question for diagnosis lay between a local cancer and a cyst, Mr. Bryant pointed out the wisdom of the question of cyst always having a first place in the surgeon's mind, for he believed it was from a neglect of this habit of thought that so many mistakes in diagnosis were met with. He drew attention to certain methods of examination which facilitated diagnosis, and to the value of different objective symptoms which might be present in the different cases. He illustrated this group, with its treatment, by giving brief notes of many interesting examples, and pointed out that these cases had mostly occurred in women after forty years of age. The disappearance of cysts by time and treatment was then discussed and illustrated by cases, but Mr. Bryant stated that such cases as these were not common, and gave no support to a practice which allowed the local trouble to continue without treatment. He believed that cases of reputed disappearance of adeno-sarcomata and of cancer were examples of mistaken diagnosis, and in reality were cysts. He had never known a tumour which was solid to disappear without surgical assistance. The reappearance of cysts which had been said to have disappeared spontaneously years before was also pointed out, and the remark made and illustrated that in one case the re-enlargement of the cyst might be genuine, and that in another the cysts might be of the proliferating kind. The third group was finally considered and the clinical features of the cases included in it carefully described. Such cases, he said, were too often regarded as being cancerous. The points for diagnosis were emphasised, and the subject illustrated by three cases worthy of study. By way of conclusion he expressed his belief that in the three groups of cases to which he had drawn attention his hearers would be able to find a place for most, if not all, the doubtful and difficult cases which would come before them, and he felt assured that if they would carry to the bedside the thoughts and methods of investigation to which he had drawn their attention their difficulties—which had been his difficulties—would be found to lessen, if not disappear, and that at any rate a working diagnosis could be arrived at in most of the cases upon which a sound treatment could be based, and that of "drifting" avoided, to the advantage of the patient and the credit of the profession.

Mr. MARMADUKE SHEILD said that the subject of the diagnosis of these cases was one of great interest and importance. Surgeons who possessed the accumulated experience of a large number of years were the only ones to speak on this subject with confidence. Mr. Bryant had used the term "adeno-sarcoma" to describe some of these cases, and to the speaker's mind no cases were more difficult to diagnose than sarcoma of the breast. Many cases classified after microscopical examination as "adenoma" recurred and were ultimately classed as sarcoma. As to the treatment of chronic indurations of the breast, were large doses of liquor potassæ to be recommended, or the internal administration of mercury and iodide of potassium with local strapping? From his own observations he was convinced that a certain number of these cases were syphilitic. He had seen cysts of the breast with such thick walls and so greatly distended with fluid that neither elasticity nor fluctuation could be recognised; such swellings had frequently been removed for cancer. The difficulty about the exploratory incision was the formation of a scar upon the breast, and he inquired if tapping with a fine trocar and injection with iodine would not suffice to cure some of the simple cysts? He had met with a case in a woman aged forty who had a hard lump in her breast. He explored it with a large trocar and cannula and found nothing. He then removed the breast, when he found a very thick-walled cyst containing putty-like material, no doubt a galactocele of ancient date. He inquired if Mr. Bryant had ever met with a dermoid cyst of the breast.

Dr. SNOW related a case in which a cyst had been evacuated and then later a malignant fungous growth protruded from the incision. He held that cysts associated with malignant disease were common—in fact, that every cyst of the breast became sooner or later associated with

Digitized by Google

malignant disease. He had never seen cysts disappear spontaneously.

Mr. TURNER related a case in which he removed a sebaceous cyst from the breast of a medical man's wife aged thirty who had borne children and in whom the growth was of some months' standing. He brought a case some years ago before the Clinical Society which he believed illustrated the possible spontaneous disappearance of sarcomatous growths. The patient, a woman, was suffering from sarcoma of the thyroid gland. He did a low tracheotomy and the growth almost disappeared. It later grew again, and then once more shrivelled up. She died from some other affection, and at the necropsy the diagnosis of sarcoma was confirmed.

Mr. L. BIDWELL said that two cases of cyst which he had seen lately had been treated by simple aspiration and had been followed by cure. In cases of tumour of the breast with retracted nipple it was often difficult to decide whether they were carcinomatous or inflammatory, and the character of the fluid evacuated by the nipple on pressure over the breast was not always a trustworthy guide as to the nature of the affection.

Mr. LOCKWOOD said he had seen a surgeon expose himself to the humiliation of discovering after the removal of a breast that the tumour was nothing more than a thick-walled cyst. This would have been avoided if he had adhered to the rule of cutting into tumours before removing them. He had seen some time ago a case of ascites due to secondary cancerous growths in the liver and great omentum. Ten or twelve years before a cyst of the left breast had been treated by puncture and injection of iodine. On examination there was a considerable mass in the left breast, and he had no doubt that when first tapped some growth was present in addition to the cyst.

Mr. BRYANT, in reply, speaking of adeno-sarcoma, said that these growths occurred in younger women than those who were the subjects of cancer. The tumour was rapidly growing, and on examination was found to be encapsuled and movable and of a soft and succulent nature. Nearly all the cases of cyst he had been relating were brought to him by medical men as malignant growths, and for this reason he found it politic to advise an exploratory incision rather than tapping. He was quite convinced that it was false to assert that the majority of cysts of the breast in middle-aged women were associated with cancer or were likely to become so, and it was wrong to lead these patients to believe that such breasts would probably become the seat of cancer. Cases of involution cyst in women who were middle-aged, or prematurely so, should be carefully watched. The character of the fluid evacuated from a cyst was certainly of value in many cases as an aid to diagnosis. His rule was to treat simple serous cysts by plugging; other cases of cyst, especially when associated with intra-cystic growth, were dissected out; where the cysts were multiple he removed the lobe or the whole gland. He had seen but one dermoid of the breast, but had met with many sebaceous cysts. A simple cyst, if it gave rise to no trouble, might be left alone; no treatment was of use to cause absorption. He had seen no good from tapping; on the contrary, harm had followed, but this harm, as being of a septic nature, might probably be avoided nowadays. The scar which resulted from exploration was usually insignificant, and where the diagnosis was in doubt between cyst and cancer the patient would usually readily submit to incision.

OBSTETRICAL SOCIETY OF LONDON.

Tubo-Uterine Pregnancy.—Uterus Didelphys.—Exhibition of Specimen.

A MEETING of this society was held on Dec. 4th, Dr. F. H. CHAMPNEYS, President, being in the chair.

Mr. BLAND SUTTON read notes of a case of Tubo-Uterine Pregnancy with Primary Intra-peritoneal Rupture and Recovery. He detailed the possible modes of termination of a tubo-uterine (interstitial) pregnancy, and compared them with those of a purely tubal one. He also related a case which occurred in his practice of a woman aged twenty-two years who had been married two and a half years and had not been pregnant. Menstruation was fourteen days overdue when she was seized with severe pain in the abdomen and vomiting. When seen she was blanched, and the physical signs pointed to rupture of a gravid tube. On opening the abdomen a large quantity of blood was evacuated and a rent was found at the right angle of the uterus from which arterial blood was issuing at several points. The bleeding surfaces were secured by silk ligatures passed through the substance of the uterus, and the tube and ovary were cut away. The uterus was found to be somewhat large, and probably owing to the large decidua which came away the patient vomited frequently during the seventy hours after operation. After the decidua had been away the patient recovered quite satisfactorily. Mr. Sutton believed that this was the first recorded example of primary rupture of the sac of a tubo-uterine gestation treated by a surgical operation. The ovum was not found, but no other explanation of the condition of the tube suggests itself but that of tubo-uterine pregnancy. Mr. ALBAN DORAN considered that Mr. Sutton had shown that the treatment of a ruptured interstitial pregnancy was relatively simple, though the danger was usually great. Amputation of the uterus was the course which had sometimes been recommended on partly theoretical grounds. Dr. Dunning[1] recently lost a case of this kind during operation. In his report he very properly dwells on the risk of performing hysterectomy on a patient already in a profound state of shock. In regard to the decidua, Mr. Sutton had shown that, so far from it being ill developed in tubo-uterine gestation, it was particularly well formed and bulky. This fact must be remembered in association with the theory that the fœtus was relatively ill developed.—Dr. Heywood asked if the size of the uterus had been measured in any way. It was only stated in the paper that it was enlarged. He agreed that the case was probably one of tubo-uterine gestation. As a result of investigations he had found in cases of extra-uterine gestation the uterus begins to grow in size just in the same way as it does in intra-uterine gestation, and if the embryo lived it went on growing and did not stop at the end of a few months. If the fœtus died involution of the uterus commenced and was completed unless prevented by complications such as would cause involution ordinarily. Hence in a case the size of the uterus was a most important factor in the diagnosis. If the uterus were not enlarged could say that either the case was not extra-uterine pregnancy at all or, if it were, the fœtus was dead and had been so long enough to have allowed involution to be completed. Of course, it was to be remembered that the uterus was not as great absolutely as in intra-uterine pregnancy; what he meant was that at any given date of pregnancy the uterus was as great in extra- as in intra-uterine gestation when in the latter case the uterus had been emptied of its contents. He asked also whether the rupture in this case had taken place through the substance of the wall of the uterus or close to the edge where the Fallopian tube emerges.—Dr. BOXALL inquired if, apart from the absence of menstruation for six weeks, there existed any evidence—e.g., morning sickness—of pregnancy having exceeded that duration; and also if Mr. Sutton had a comparison with the character of preceding periods to disposed to regard the last flow prior to the operation as a regular period or as a hæmorrhage accompanying abnormal gestation and symptomatic of it.

Dr. ARTHUR GILES read a paper on a Case of Uterus Didelphys, with remarks on the Clinical Importance of Malformation. He recalled the three principal types of double uterus—viz., septus, bicornis, and didelphys—a description of these being given, with outline figures. He next described his case, observed at the Middlesex Hospital. The patient complained of a protrusion from the vagina; this was found to be the remains of the vaginal septum. Under ether the exact condition was ascertained; it was illustrated by a drawing. Dr. Giles discussed the clinical features of the condition as illustrated by recorded cases. Abstracts of these were given, under five headings: 1. Cases of unilateral atresia with retained menstrual products, twenty cases. 2. Pregnancy in one-half of the uterus, eight cases. 3. Simultaneous pregnancy in both halves, two cases. 4. Cases uncomplicated by atresia or pregnancy, six cases. These twenty-one cases (including Dr. Giles's) were all he could find recorded during the last twenty-five years occurring in living adults. Two recently published cases were also given. 5. Cases discovered on the post-mortem table, four cases. A table was given of the cases. one clinical cases, illustrating the following

[1] American Gynæcological and Obstetrical Journal, November
[2] Annales de Gynécologie et d'Obstétrique, October 1889.

Digitized by Google

1. Age; most of the patients were under thirty. 2. Marriage; fifteen were married; in two there was dyspareunia. 3. Parity; pregnancy occurred in fourteen of the fifteen married cases; eleven had borne children, and three had miscarried. Among the eleven sixteen labours occurred, of which ten were natural. The six cases of dystocia were as follows: obstruction to labour by the empty retroverted half, three cases; obstruction by the vaginal septum, one case; forceps, two cases. 4. In four cases the two halves were of equal size; the right was the larger in six and the left in eleven. 5. In only one case the vagina was originally single; in six there was atresia of one half; in the remainder the two vaginæ were patent and separate. 6. Menstruation was slightly delayed; it occurred—

At 14 in 3 cases.	At 16 in 4 cases.	At 18 in 1 case.
At 15 in 4 cases.	At 17 in 1 case.	At 26 in 1 case.

It was regular in twelve out of sixteen recorded cases, and painless in twelve out of fifteen. In one case the two halves menstruated separately. In the eight cases of single pregnancy there is mention in four of a decidua in the non-gravid half. The clinical complications that may arise are: 1. Unilateral atresia, with retained menstrual products. 2. Dyspareunia. 3. Double vaginitis or endometritis, unsuccessfully treated by application to one-half only. 4. Obstruction to labour by the retroverted non-gravid half. 5. Obstruction due to the vaginal septum. 6. Retained and undiscovered products of conception in one-half in cases of double pregnancy. A bibliography was appended.—Dr. GALABIN referred first to two cases of uterus didelphys, one associated with congenital absence of the vagina, the other with fibroid tumour of one uterus only, notes of which were appended to Dr. Giles's paper. In a third case he had met with dystocia of a very unusual kind arising from a double uterus, not a complete uterus didelphys, but rather a uterus bicornis, yet not of the usual kind, for the uteri were completely separate, without any uniting band, even below the level of the internal os. The lower part of the cervix, however, was common. The woman had had several children normally; but for some unexplained reason, in her last pregnancy the poles of the two uteri became turned in opposite directions. The result was that the ovum, which began in one uterus, made its way also into the other. At full term one fundus was in the normal position; the other fundus lay in a reversed position in the pelvis and contained the head of the fœtus. The patient was admitted into Guy's Hospital in labour, and the true state of affairs was naturally not discovered till abdominal section had been performed. A large hard mass filled the pelvis, and was thought to be a fibroid tumour. The os was quite out of reach, the liquor amnii had escaped, and a hand of the fœtus could just be touched. Cæsarean section having been performed and the fœtus removed, the displaced body of the uterus at once sprang back to its normal position, and the two halves lay side by side. The incision, at first straight, was thus converted into an elongated U-shape, and the centre of the U ran through very thin overstretched cervical tissue. The edges had become so distorted that it was very difficult to sew up the incision satisfactorily. This was at length accomplished, and the patient recovered without a bad symptom, the child also being alive.—Dr. AMAND ROUTH thought these cases were not so rare as the scanty bibliography appeared to indicate. He had seen two cases. The first was described and pictured in the *Illustrated Medical News*, March, 1889. The woman was married, aged twenty-four, and had had three children. The catamenia began at thirteen and a half. There was amenorrhœa during pregnancy. The vaginal septum had been torn through, but the two uteri were quite distinct, one being anteverted, two and a half inches long; the other (right) was three and a quarter inches long and retroverted. Bimanually the uteri were felt to be quite separate, but joined loosely by a thick transverse band. She was suffering from subinvolution in the large uterus. His second case[3] was that of a single woman aged twenty-seven years who was under the care of Dr. C. H. F. Routh. She was found to have a tense vaginal ridge on the left side continuous with an elastic mass in the pelvis on the left of what appeared to be a normal uterus. The vaginal ridge was incised and its contents allowed to escape. It was then found to be a case of distinct double uterus and double vagina, with left vaginal atresia, producing left hæmatocolpus and hæmatometra. The left uterus eventually contracted down to two and a half inches, but remained retroverted.—Dr. GILES, in reply, agreed with Dr. Amand Routh as to the degree of rarity of these cases. He was interested in the cases related by Dr. Galabin, and would ask permission of the society and of Dr. Galabin to include a short account of the two cases of uterus didelphys in the paper in the form of an appendix.

The following specimen was exhibited:—Dr. CULLINGWORTH: Supposed Tubo-Ovarian Cyst.

[3] Transactions of the Obstetrical Society, vol. xxxvi.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held on Dec. 6th, Dr. A. SYMONS ECCLES, President, being in the chair.

Dr. SEYMOUR TAYLOR showed: 1. A man aged thirty with Symmetrical Drooping of the Pinnæ, which might, he suggested, be an instance of maternal impression, the mother having sustained a fright from a rat when she was four months pregnant. 2. A woman presenting all the classical signs of Myxœdema, but the thyroid body was enlarged, though probably dystrophic. He believed that, as in the case of disease of the adrenals, any actual disorganisation of the thyroid body would produce myxœdema. 3. A woman with the usual signs of Myxœdema, except that she was remarkably pallid and was without the usual circumscribed blush on the cheeks. He believed that there existed a distinct variety of pallid cases. In this case there was no albuminuria or evidence of cardio-vascular changes.—Dr. DOBSON remarked that in one of his cases there had been albuminuria, which disappeared under the thyroid treatment.

Mr. BIDWELL showed a case of Sclerosis of the Superior Maxilla in a woman aged fifty-two. For eight years there had been swelling of the left upper alveolus, and recently severe aching pain. A molar tooth was extracted, and since then the swelling had greatly decreased, thus showing that it was not an osteoma. There was no evidence of syphilis or acromegaly.

Mr. MCADAM ECCLES, for Mr. PAGET, showed a case of Resection of the Elbow for Compound Fracture of the Humerus.—Mr. BIDWELL said that when possible resection should not be performed in these cases, since a stronger joint thus resulted.

Mr. KEETLEY showed a boy on whom he had performed an operation for Radical Cure of Hernia with Undescended Testis by bringing the organ into the scrotum and fixing it there by suture to the adjacent tissues of the thigh.

Mr. MCADAM ECCLES showed a girl aged thirteen with at least twenty-three Exostoses. There was a history of rheumatism, but none of syphilis. The mental condition had not been noted.—Dr. SHUTTLEWORTH quoted the case of a boy thus afflicted who was imbecile and a girl who was mentally defective.

Dr. ALDERSON showed a case of Rodent or Epitheliomatous Ulcer on the Nose of a man aged ninety. There had first been a wart, which had been treated with caustics. He believed the ulcer to be epitheliomatous.—Mr. BIDWELL concurred in the diagnosis and advised operation under cocaine.—Mr. MCADAM ECCLES thought it was rodent ulcer owing to its early history, its slow growth, and the non-involvement of glands. He suggested ethyl chloride as a local anæsthetic.—Mr. KEETLEY discussed the differential diagnosis and believed this case to be probably one of rodent ulcer.—Dr. POTTER held that rodent ulcer was an early stage of epithelioma.

ISLINGTON MEDICAL SOCIETY.

Lunacy and General Practice.

THE second meeting of the session was held at the residence of Mr. G. T. KEELE, St. Paul's-road, Highbury, on Nov. 26th.

After confirmation of the minutes and election of new members, a paper was read by Dr. T. SEYMOUR TUKE on Lunacy and General Practice: some Thoughts on the Duties, Difficulties, and Responsibilities of the Private Practitioner. Dr. Tuke began by saying that it was incumbent on every man going into private practice to know more than something about lunacy. It had been much neglected, but he was glad to be able to hope that in the future, instead of the instinctive dread that was so commonly felt when a case of insanity was met with, all medical men would be

Digitized by Google

prepared to act fearlessly, spontaneously, and self-reliantly on their own responsibility, and be better able to know when to intervene. Asylum experience is of course necessary, but careful attendance at demonstrations, reading, and observation are of importance. Dr. Tuke would go further, and say that all men, whether medical or not, would be the better for having some knowledge of the subject, and of first principles and possible results, for the most important thing in lunacy is early recognition and early treatment. The general public know nothing of lunacy. They have been allowed by those who should guide them aright to remain in a condition absolutely behind the times—namely, one some fifty years old—instead of keeping pace with the tremendous changes that have taken place. Outcry is made if anything goes wrong, but little is thought or known of the zeal and self-sacrifice of those who devote their lives to the study of insanity and the care of the insane in both public and private asylums. The private practitioner has much to think of in the early stages. There are friends and relatives (often all in opposition to each other) to advise, nurses to provide, treatment to be considered, changes, removals, and choice of places to be decided on, and much thankless work to be done. After a few words on the legal processes in private and pauper cases, and on the subject of writing certificates, the kinds of cases that were most likely to confront the private practitioner were mentioned, the puerperal, melancholic, and those cases where depression was a marked symptom from any cause, too often met with in our daily papers, and too often consigned to oblivion with the verdict of "temporary insanity," a thing that rarely, if ever, exists. Under this head come cases of imaginary impotence, disease, unworthiness, wickedness, and bankruptcy, all of which should never be treated lightly. Maniacal cases (apart from temporary febrile and alcoholic conditions) and cases of youthful, senile, hysterical, and climacteric insanity were mentioned, and special attention drawn to the early recognition of general paralysis of the insane. All these depend on the watchfulness and action of the "usual medical attendant." Dr. Tuke concluded by protesting against many of the cruel, ignorant, and idle things that had been said and written of late about insanity and those who made it their special study, and against the violent attacks levelled at individuals started by those who are either ignorant or wilfully desirous of advertising themselves and misleading the public.

Mr. KEELE, while quite concurring in the advice of Dr. Tuke as to the benefit of early recognition and treatment in cases of insanity, spoke of the many difficulties a practitioner had to encounter in dealing with such cases. He exemplified this by narrating a case that had given him much trouble and anxiety last summer. A man gradually developed insanity, imagining there was a league of men against him, and by falsely accusing his relatives and threatening them with violence. He was unable to get this man to go into the country for a change, for, like Dr. Mack's patient, he positively refused to go. One day the man jumped out of a window to escape his imaginary foes, and Mr. Keele then certified to his being of unsound mind, and the relieving officer removed him to the infirmary of the Islington Workhouse. The patient was duly seen by the magistrate and medical officer, with the result that a detention order of fourteen days was given. At the end of that period the man was discharged from the infirmary without any previous notice being given to his relatives. He was fortunately met in the street by his sister and taken home. Mr. Keele had written to the relieving officer and stated he considered such conduct on the part of the authorities as cruel and wrong. The man continued at home for about a month, his delusions more intense, and his threats of violence increasing. Mr. Keele then advised the relatives to consult a specialist in lunacy, with the result that an urgency order was obtained for his removal to St. Luke's, where he is still, after two months, a patient requiring careful observation.

After some remarks by Dr. DUCAT, Dr. REID, Mr. WORLEY, and Mr. KING, a vote of thanks was passed to Dr. TUKE, and the meeting adjourned.

LIVERPOOL MEDICAL INSTITUTION.

Lamellar Fibromata.—Exhibition of Cases and Specimens.

A MEETING of the Pathological Section of this society was held on Dec. 5th, Mr. G. G. HAMILTON being in the chair.

Dr. ABRAM read a short paper upon Lamellar Fibromata, which was illustrated by specimens and by lantern slides. The lantern slides were prepared from photographs taken by Professor Boyce.—Dr. BUCHANAN said that in a specimen he had examined the structure was identical with that of a hydatid membrane, and no cellular elements were observed.—Dr. WIGLESWORTH called attention to the similarity in microscopical structure displayed by Dr. Abram's specimens and the fibrous thickenings of cartilaginous consistence which are not infrequently met with on the splenic capsule in old people and alcoholic subjects, and he said the latter formations might be described as lamellar fibromata.—Mr. HAMILTON, Mr. PAUL, Mr. LARKIN, Professor BOYCE, and Professor SHERRINGTON took part in the discussion, and Dr. ABRAM replied.

Dr. BUCHANAN showed the Stomach from a case of Carbolic Acid Poisoning, and a beautiful drawing of the appearance of the specimen when fresh. He drew attention to the immunity of the tongue and the glosso-epiglottidean folds, and pointed out that the duodenum was not affected in the least degree. The stomach was greatly contracted, and the mucous membrane had a greyish, brilliant pearly lustre like oily putty.

Dr. WIGLESWORTH showed (1) the Brain from a case of Hydrocephalus; and (2) the Brain from a case of Cerebral Tumour.—Mr. PARKER referred to a case of Brain Tumour in which, some six years ago, he had removed a tumour from the right Rolandic area, the patient being still alive and well. In his case, however, the diagnosis had not been one of great difficulty, unlike Dr. Wiglesworth's, in which diagnosis of the condition was impossible.

Dr. A. W. CAMPBELL showed some Brain Sections from a case of Cerebral Hæmorrhage prepared by a new method. They were made in March, 1895, and had satisfactorily retained their colour. The following is the method of procedure: 1. Immersion of the brain in a 1 in 20 carbolic acid solution for a few days. 2. Sections one-eighth to a quarter of an inch in thickness are then cut. 3. The sections are placed face downwards upon a piece of glass, surrounded by a framework of wood, and covered with melted paraffin (46° C.); the paraffin is then allowed to set. 4. The glass is then lifted up, some Farrant's solution poured over the section, and the glass replaced, the edges being sealed by Canada balsam. 5. A plaster-of-Paris frame is then moulded on to the sides and back of the specimen.

Mr. MURRAY exhibited some patients suffering from Lymphangeioma and Sections of the Growths.—Mr. PARKER had lately had a similar case. He discussed the questions of angeiomata and lymphangeiomata, and asked for an opinion on the subject of "degenerated nævi," which he held to be lymphangeiomata.—Professor BOYCE, Mr. HAMILTON, and Mr. BARENDT also spoke.

Dr. ANNETT showed specimens of Meningo-encephalitis.

Mr. THELWALL THOMAS exhibited specimens of Tuberculosis of the Peritoneum snipped out during an operation. The specimens showed typical tuberculous granulations. The boy, now eighteen months after operation, is in perfect health. He also showed an Implantation Cyst from the Head of the Metatarsal Bone of the Great Toe. The epithelial graft had no doubt been made in the process of scraping for caries, which had been performed on three occasions. He likewise showed two cases of Multiple Epitheliomata: (1) epithelioma in the centre of the lower lip removed by operation, followed three years later by two separate and distinct growths in the same lip, but away from the scar; and (2) hard warts of the lip and juicy epithelioma of the tongue.

Mr. MURRAY and Mr. PAUL brought forward a case of Sacro-coccygeal Tumour in a Boy aged two years. Mr. Paul said the growth measured five inches by four inches by three inches, and was situated between the rectum and the coccyx, projecting on the surface behind the anus where the skin was ulcerated over it. The central part consisted of a soft fungating growth of malignant appearance, composed for the most part of trabeculæ of connective tissue set with one or more layers of cubical epithelium, but also containing tracts of skin, with hairs, sebaceous and sweat glands. The outer parts of the growth were dense and fibrous and contained immature bone. In another part Lieberkükn's follicles were recognised. The structure was very complex, and discussing the relation of this with other tumours Mr. Paul thought it should be grouped with the congenital renal and thyroid growths.—Mr. PARKER said Mr. Paul had not mentioned the adenoid variety of these growths, of which he had shown a specimen at the previous meeting. He considered that the growth was

Digitized by Google

not malignant, but simulated the malignant state from the rupture of a cyst and subsequent septic inflammation.

Mr. G. G. HAMILTON showed specimens of (1) Union of Intestine by Murphy's Button; and (2) Cholecyst-colostomy.

Dr. LEIGH showed photographs of Count Orloff. He considered the "wonder" to be an example of osteo-malacia.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Nephrectomy for Hydronephrosis.—A Case of Diabetic Neuritis.—Exhibition of Specimens.

A MEETING of this society was held on Dec. 4th, Dr. CATTLE being in the chair *pro tem.*

Mr. ANDERSON read a paper on Nephrectomy for Hydronephrosis. The details of five cases were given, all of which recovered after operation. In two cases, a boy aged ten and a woman aged thirty-seven, the usual symptoms of hydronephrosis were present, such as attacks of spasmodic pain, and formation of a tumour which disappeared coincidently with a large flow of urine and relief of the pain. In both these cases the origin of the ureter was reduced to a pin-hole, the kidney substance atrophied, especially in the case of the female, whose symptoms had lasted twenty years, and the pelvis was dilated to the capacity of a pint or more. In three other cases, one in a man, the hydronephrotic condition was associated with mobility of the organ. The case in the man was successfully treated by suturing the kidney to the lumbar muscles. The same treatment was pursued in the case of a female, but the kidney subsequently broke loose. This was due, it was thought, to the stitches cutting through the attenuated kidney substance. The patient was seized with rigors, high temperature, and swelling of the abdomen. On exploration the kidney was found swollen and livid owing to twisting of the pedicle. It was removed, and the patient recovered. In a third case of hydronephrotic and movable kidney extirpation was at once carried out. The paper concluded with a review of the various causes of hydronephrosis, Mr. Anderson remarking that he believed his cases of pin-hole ureter were almost unique.—Dr. WATSON made some remarks.

Mr. PRYCE read notes of a Case of Diabetic Neuritis in a man aged fifty years who had drunk freely of beer and spirits. He was ataxic, but Romberg's symptom was not well-marked. In the left leg no knee-jerk could be obtained, an erythematous rash was present, and there were trophic ulcers and anæsthetic patches on the foot. He had suffered from sciatic pains. The urine contained much sugar.—The CHAIRMAN and Mr. ANDERSON made remarks, to which Mr. PRYCE replied.

Mr. ANDERSON showed (1) an Ovarian Tumour weighing ten pounds; (2) a Tumour of the Right Lobe of the Thyroid Gland; and (3) two Hydronephrotic Kidneys with Pin-hole Ureters.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Vaginal Cœliotomy.

AN ordinary meeting of this society was held at the Birmingham Medical Institute on Dec. 4th, the President, Dr. T. EDGAR UNDERHILL, being in the chair.

Mr. MARRIS showed for Dr. SIMON a boy seven years of age afflicted with Leucoderma. He was one of ten children and had always been weaker, mentally and physically, than the rest of the family. Twelve months ago his hair, which had been almost black, began to fall off in patches. As the hair grew again it was found to be pure white. At present the head is well covered with a growth of very soft white hair, except for a band about two inches broad extending round the back of the head from ear to ear which retains its original dark colour. Below this band the hair is again white. Scattered without symmetry over the body and limbs are patches of white skin surrounded by a brown pigmentation, which fades gradually into the natural skin tint. The areas of white skin vary in size. The skin of the face is uniformly dark, contrasting markedly with the white hair. Under the microscope the hairs are seen to contain a few relics of the dark medulla. There is no deepening in colour of the nipples and there is no pigmentation within the mouth.

Mr. BARLING showed Photographs of an Unusual Case of Syphiloderma, with hæmorrhagic centres to the individual patches.

Mr. HAMMOND SMITH showed a Knee-joint with Fracture of the Outer Head of the Tibia extending into the joint. The cause was a fall of coal, which produced a compound fracture of the leg unconnected with that into the knee-joint. Large hæmorrhage into the joint and indistinct crepitation led to the diagnosis of the outer fracture and amputation through the lower part of the thigh.

Mr. BARLING showed a Sequestrum from a case of "Quiet Necrosis" in a male aged fifty-two, which in many ways simulated sarcoma of the femur. There was a massive swelling encircling the bone and completely fixed on it, and without any of the signs of inflammation. Incision into this revealed dense inflammatory infiltration of the muscles and a small quantity of semi-fluid material at the back of the femur in contact with a small patch of bare bone, whence the sequestrum eventually separated. The necrosis followed double pneumonia some three months before, the swelling appearing during convalescence.

Dr. PURSLOW showed a specimen illustrating Perforation of the After-coming Head. The patient was a primipara, and when Dr. Purslow saw her attempts had been made, under chloroform, to deliver the head by traction on the body and by forceps. Pulsation in the cord had ceased some hours previously. The perforator was passed through the roof of the mouth, and after evacuation of brain matter the head was delivered by traction on the body. Attention was drawn to the advantages offered by the roof of the mouth as a site for perforation of the after-coming head.

Dr. SHORT showed the Gall-bladder and Ducts from a man aged seventy-nine years who died from Senile Asthenia. A few days before death jaundice set in, with bilious urine; there was no pain and the stools were dark in colour. After death the gall-bladder was found full of gall-stones, contracted, and fibrosed. The common bile-duct was much dilated and partially obstructed by a stone. The dilatation appeared of old date, but no history of any attack resembling hepatic colic could be obtained.—Dr. SHORT also showed the Stomach of a man aged forty. Three years before death the man had extremely severe hæmatemesis, followed by pain, but unaccompanied by signs of hepatic cirrhosis. The pain, at first paroxysmal and afterwards constant, persisted, and the case ran the clinical course of a pyloric cancer, with dilated stomach, but no tumour was felt during life, and the pain at times was intense. He refused operative interference. At the necropsy a large flat ulcer of the size of a crown-piece was found on the posterior wall of the stomach, close to the pyloric aperture, which was narrowed by the hard, raised edge of the ulcer. Microscopically no evidence of cancer could be found.

Dr. RUSSELL showed a specimen of Dilated Duodenum from a case of Peripheral Neuritis.

Mr. W. EDELSTEN BRACEY showed a Portable Irrigator the main feature of which was a bucket of sufficient size which was collapsable in the manner of the well-known drinking cup. The apparatus was well made, there being absolutely no leakage, and the price was moderate.

Mr. JOHN W. TAYLOR read a paper on Cases of Vaginal Cœliotomy. A description was given of the operation, followed by a series of cases illustrating Mr. Taylor's experience of vaginal cœliotomy as applied to vaginal fixation of the uterus, removal of the appendages, igni-puncture of the ovaries, and separation of pelvic adhesions. Mr. Taylor concluded his paper with a description of the part played by this operation in the practice of Professor Martin and Dr. Dührssen of Berlin, and drew attention to the important position which the operation was rapidly assuming and to some of its more recent developments.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Cranial Hypertrophy.—Fracture of the Ethmoid Bone with Basal Meningitis.—Method of measuring the Shortening at the Neck of the Femur.—Epidemic of Hysteria.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 29th, Mr. MAYO ROBSON, President, being in the chair.

Mr. HARTLEY showed an unusual case of Cranial Hypertrophy in a boy aged twelve years. The condition was congenital and almost entirely confined to the cranium, the

Digitized by Google

bones of the face being very slightly affected. The principal bosses were two—one at the vertex and a second on the left side of the skull involving chiefly the parietal region. In addition there were irregular thickening of the occiput and an invasion of the orbits producing marked proptosis, absolute loss of one eyeball, and complete blindness in the other. The upper jaw was much compressed laterally, the two halves forming a very acute angle in front and the teeth growing very irregularly. (Plaster casts by Mr. MARGETSON were shown.) The lower jaw was normal. There was no evidence of intracranial disease, of hydrocephalus, or congenital syphilis, and no deformity of the limbs or joints. The patient's mental development is quite up to the average; he has a good ear for music, and is being educated on the Braille system. The case seems nearest akin to leontiasis ossea.—Dr. GRIFFITH mentioned that the museum of the medical school contained a skull closely resembling that in the case just recorded, and he himself had shown a somewhat similar case at a previous meeting.—The PRESIDENT had seen a somewhat similar case improved by iodide of potassium.—Dr. EDDISON asked whether there was any evidence of syphilis in the parents; he thought the appearance suggested it. It was unlike any case of osteitis deformans that he had seen, nor was it ordinary hydrocephalus.

Mr. W. H. BROWN read notes of a case of Fracture of the Ethmoid Bone with Basal Meningitis. The patient, a boy aged sixteen years, was struck over the occipital region of the skull by a falling stone; he fell forward, his forehead coming violently into contact with the ground. He was unconscious for a short time. No special symptoms were noticed, but he was kept in bed. On the third day, when sitting up, a copious watery discharge ran from both nostrils and continued for six days, when it ceased. The temperature rose to 104·5° F. and was accompanied by intense frontal pain, photophobia, tinnitus, and a transient strabismus. Three weeks after the accident he was admitted to the Leeds Infirmary under the care of Mr. Brown. There were then no external signs of injury beyond some discolouration of the skin at the root of the nose. He complained of severe temporal pain; the movements and sensations of all the limbs were normal; the temperature was 100°; there was convergent strabismus affecting both eyes, the pupils were dilated and reacted slightly to bright light, and double optic papillitis was present. Later, vomiting occurred at irregular intervals; the boy was irritable and at times delirious, but gradually his symptoms disappeared and he is now quite well. Mr. Brown believed that only a few cases of basal fracture with nasal discharge of transparent fluid recovered, and said that a discharge from the Schneiderian membrane might be taken for cerebro-spinal fluid. He thought the fluid in this case was cerebro-spinal, on account of the quantity and absence of any affection of the sense of smell.—Mr. SECKER WALKER said he had lately examined the eyes again, and all the ocular symptoms had disappeared except some slight swelling of the right optic disc. Vision in each eye is good. He mentioned that at least four cases of persistent discharge of cerebro-spinal fluid from the nose associated with double optic neuritis had been reported, but in these cases there was no history of traumatism.—Mr. WARD and Mr. LITTLEWOOD both thought that the ice-bag was of little value in the treatment of head injuries.—Dr. TREVELYAN thought it was a typical example of traumatic cerebro-spinal meningitis both in its symptoms and temperature chart. He observed that the prognosis of these cases of non-tuberculous meningitis was a matter of exceptional interest. The longer the disease had lasted after a certain point, the better the patient's chance of recovery. The particular micro-organism setting up the disease was also a very important matter. Spinal puncture might in the future throw light on this latter question, and also show how far the pathological processes might extend in the direction of pus production and yet be consistent with recovery.

The PRESIDENT demonstrated a Method of measuring the Shortening at the Neck of the Femur which he had employed for several years, and which he believed had not been hitherto described. The method consists in drawing a transverse line from the tip of the great trochanter forward and inwards across the front of the thigh on each side, and dropping a vertical line to meet this from the tip of each anterior superior spine; the latter constitute the measuring lines in question. The advantages presented by these measurements are (*a*) the ease with which they can be made with the patient in the dorsal decubitus; (*b*) the degree of exactitude which the method renders possible; and (*c*) the manifest advantages for demonstration purposes of seeing simultaneously the limbs which have to be compared.

Mr. J. CROSSLEY WRIGHT read notes of an Epidemic of Hysteria which took place on the girls' side at the Crossley and Porter School. The patients were fourteen in number and varied in age from eleven to fourteen years. The cases occurred between Nov. 11th and 24th, and in the majority one type was distinguishable—viz., clonic rhythmical spasm of the upper limbs varying in intensity between a fine tremor and coarse violent movements involving the whole of the trunk. In some of the cases the elbow-joint was rigidly extended, the fingers being flexed firmly into the palm, while the chief motion was at the shoulder-joint, giving rise to forcible alternate abduction and adduction as well as internal rotation of the whole limb. In two cases there was a distinct hammering action of the clenched fist against the side, table, or against any surface with which it was placed in contact. In a single instance there was spasm of the eyelids, with an occasional quick opening and shutting. No definite cause for the commencement could be made out; some of the girls were working for examination. The treatment was the same in all the cases—viz., isolation, rest in bed, with milk diet, faradaism, a succession of blisters in order to cause pain to the moving parts, and for drugs valerian and bromide of potassium. That which seemed to have the greatest effect was the blistering, and a marked improvement was at once made out.—Dr. BARRS considered that tremor was a common symptom in hysteria.—Dr. EDDISON advocated a more vigorous line of treatment and asked if it was certain that, as Mr. Wright had stated, the movement continued during sleep.

The following card specimens were shown:—The PRESIDENT showed: 1. Part of the Right Lobe of a Liver weighing half a pound, removed for Carcinoma from a patient aged fifty-two. The patient has progressed satisfactorily since the operation a week before. 2. Carcinoma of Small Intestine removed by Enterectomy and Suture over Decalcified Bone Bobbin, the patient recovering eight days after operation. 3. Fractured Internal Semilunar Cartilage removed for lameness which had existed for three years. It had produced all the symptoms of loose cartilage.

Mr. LITTLEWOOD: Case illustrating a New Method of Tendon Suture.

Mr. W. H. BROWN: Case in which the Urachus remains Patent, a large quantity of Urine passing by the Umbilical Opening.

Mr. SECKER WALKER: Case of Severe Symblepharon relieved by a modified Teale's Operation.

Dr. T. WARDROP GRIFFITH showed two cases of Congenital Cardiac Disease. One was diagnosed as of the usual type of pulmonary stenosis, with consequent imperfection of the cardiac septum, and the other presented mixed characters. He also showed a case of a man suffering from Addison's Disease who was entering on a course of Treatment by Suprarenal Extract.

CARDIFF MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Increase of General Paralysis in England and Wales.

AN ordinary meeting was held on Dec. 6th at the society's new rooms in Queen-street, the President, Alderman EDGAR JONES, M.D. Durh., being in the chair.

Dr. PATERSON showed three cases of Graves's Disease, in all of which there was neither exophthalmos nor V. Graefe's sign.—Dr. C. T. VACHELL thought the slight thyroid enlargement was of a simple nature and the accelerated pulse due to a neurotic temperament.—Dr. JOHN WILLIAMS spoke, and Dr. PATERSON replied.

Mr. J. LYNN THOMAS showed: 1. Scirrhus of Male Breast, the size of an orange. 2. Vermiform Appendix recently amputated after the Seventh Attack of Typhlitis, the patient doing well. 3. Calculous débris removed from the left kidney, the chief symptoms being hæmaturia and extreme irritability of the bladder, the location of the mischief being differentiated by the cystoscope. Eighteen months after the nephrolithotomy the patient's health and urine were normal. 4. Calculus weighing six drachms suprapubically removed from a girl aged nine years. 5. Alternating Calculus weighing six ounces six drachms removed by the combined perineal and suprapubic method. The combined method greatly facilitated the removal of the large stone.—

Digitized by Google

Dr. HERBERT VACHELL observed on the rarity of scirrhus of the male breast, he having only seen one in the practice of the late Mr. John Wood.—Dr. COOK had seen a calculus in a young girl, and Dr. RHYS GRIFFITHS made some remarks and showed two calculi removed by lateral lithotomy.

Dr. STEWART of Bridgend read a paper on the Increase of General Paralysis in England and Wales. He treated the subject chiefly from the statistical standpoint, and showed in which grades of society and sex the increase took place.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Exhibition of Cases and Specimens.—Oxaluria.—The Results of Surgical Measures in a Series of Cerebral Cases.

THE second meeting of the seventy-fifth session was held on Dec. 4th, Dr. ARGYLL ROBERTSON, President, being in the chair.

Dr. LUNDIE showed Photographs of a rare Tumour of the Upper Lip in a boy aged thirteen years. The tumour was situated in the thickness of the lip equi-distant from the skin and mucous membrane.—Mr. STILES examined the tumour after removal and reported that it was of the nature of an endothelioma undergoing myxomatous degeneration with here and there cartilaginous development. Two specimens were shown under the microscope.

Dr. ALLAN JAMIESON showed a case of Morphœa or Circumscribed Scleroderma. The disease had begun sixteen months before as a small point-spot under the right eye. Other patches appeared later. They all had a violaceous tint fading on pressure. All the lesions were restricted to the skin supplied by the second and third branches of the fifth nerve. There was no lardaceous deposit.

Dr. FELKIN showed a new form of Safety-pin with a special catch to prevent it becoming accidentally unfastened.

Mr. STILES showed a Pneumatic Rubber Truss for Hernia in Infants. It possessed many advantages over the spring truss, especially in difficult cases. It set up no irritation, and the infant did not grow out of it.

Dr. J. C. DUNLOP read a contribution on Oxaluria and the Secretion of Oxalic Acid in the Urine. The paper was an abstract of work done in the laboratory of the Royal College of Physicians of Edinburgh. He first glanced at the literature of the subject, pointing out the contradictory nature of the chemical and clinical observations. In his early observations he had used Neubauer's method, but this was found so unsatisfactory that a new method had to be devised. Observations with the microscope showed that oxalic acid was frequently present in the urine, and from chemical analysis he found that the urine of all men eating an ordinary mixed diet contained oxalic acid, and that consequently oxalic acid was a normal constituent of the urine. Oxalic acid was usually described as precipitated in the urine as a calcium salt in two forms, octahedral and dumb-bell. The latter, however, he found to be crystals of carbonate, not oxalate. What determined the precipitation of crystals of oxalate of lime had not previously been shown. The balance of evidence seemed to show that precipitation was prevented by the presence of acid phosphate of soda, and possibly by the presence of other solvents. It was not due to the presence of excess of lime. In urines depositing crystals the average percentage of oxalic acid present was found to be 0·0025, while in those not depositing crystals it was 0·0010. He therefore concluded that precipitation showed increased percentage of oxalic acid. Many theories had been advanced to show that oxalic acid could be produced in the metabolic changes of the proteids and carbohydrates, but Dr. Dunlop found that the excretions could be arrested by a restricted diet free from oxalic acid. He hence concluded that food-stuffs were the source of the oxalic acid in the urine, and not the metabolism of proteids or carbohydrates. He had carried the experiments further by adding a substance containing oxalic acid—e.g., tea—to the diet, when an excretion of oxalic acid took place. The clinical condition oxaluria described by Begbie, presented besides the condition of the urine, the well-known symptoms of pains, dyspepsia, and nervous symptoms. The deposition of crystals of oxalate of lime indicated increased excretion of oxalic acid, but to what this increased excretion was due was not indicated by examination of the urine. The pains in the lumbar region were probably due to mechanical irritation due to the passage of the crystals. The dyspeptic symptoms in oxaluria are, Dr. Dunlop considered, identical with acid dyspepsia, and the treatment in both conditions was similar. The nervous symptoms in oxaluria were identical with those in acid dyspepsia. The consideration, then, of all the symptoms of oxaluria showed that it did not differ from acid dyspepsia except that the deposition of oxalate of lime crystals in the urine occurred with more regularity. Oxaluria, he considered, was no pathological entity, and the recognition of oxalates in a urinary deposit had no diagnostic value.—Dr. NOEL PATON complimented Dr. Dunlop on the value of his contribution, and thought he had proved that oxalic acid was not formed by any metabolic process, but taken in the food. Dr. Dunlop had exploded an old and popular fallacy.—Dr. GRAHAM BROWN was not inclined to abandon his old friend oxaluria. Cases had been described where oxaluria and diabetes alternated, and then in dogs, when the respiration was interfered with and dyspnœa produced, oxalates appeared in the urine, which disappeared as the dyspnœa disappeared.—Dr. GILLESPIE suggested that oxalates might be found in the intestines by the action of organisms in starches, &c. He suggested experiments with guaiacol or some other intestinal antiseptic.—Dr. STOCKMAN thought Dr. Dunlop had proved his point that taking a healthy man oxalates in the urine could be got rid of or produced at will. He thought, however, observations should be made on an individual who had the faulty habit of transforming food into oxalates and excreting them.—Dr. JAMES expressed his belief that oxalates might be the result of altered metabolism.—Dr. W. RUSSELL thought there was some misapprehension as to the position of oxaluria. It was not treated as a special disease in all English books, and it had been long known that it was associated with gastro-hepatic derangements. While Dr. Dunlop had proved his main contention in the case of healthy persons, it would be well to make investigations in morbid digestive conditions before it could be absolutely accepted that vegetable food was the sole source of oxalates, and that they might not be derived from other substances, as a result of faulty digestion.

Dr. G. A. GIBSON read a paper on the Results of Surgical Measures in a Series of Cerebral Cases. He gave a record of seven cases of cerebral disease where surgical interference had been considered advisable. Case 1: A patient complained of persistent headache, with loss of power in the left arm and leg. The left side of the face was involved in the paresis, and the speech was indistinct. The pain in the head started from a swelling situated three inches and three-quarters behind the glabella and a little to the right of the middle line. It was evidently of a bony nature. Optic neuritis was present. Syphilis having been excluded, and there being no evidence of tubercle, the tumour was held to be sarcomatous. The patient would not consent to operation. Three months afterwards he was readmitted to the Edinburgh Royal Infirmary in a very much worse condition. Mr. Annandale operated over the middle third of the motor area on the right side and removed a large glio-sarcoma. The patient made an uninterrupted recovery and had remained in good health ever since, having recovered the use of almost all his muscles. Had the operation been performed earlier Dr. Gibson thought in all probability he would have regained more of the power of fine adjustment. Case 2: A man aged thirty years had had syphilis. On admission he was in a torpid state. The pupil reflex was sluggish. The left leg, arm, and side of face were paralysed. Coma supervened. Mr. Alexis Thomson operated in the middle zone of the right Rolandic region. The dura mater and brain bulged very markedly, but nothing abnormal could be found. After the operation the patient recovered consciousness, but there was no improvement in the paralysis. Three days afterwards he collapsed and died. Post mortem a tumour was found occupying the right corpus striatum and the knee and anterior portion of the posterior limb of the internal capsule. Case 3: A married woman complained of headache, giddiness, and difficulty in walking. The headache was deep-seated and strictly localised to the frontal region over the left eye. There was optic neuritis, with nystagmus. The left pupil was larger than the right. There was no paralysis with the exception of the soft palate. The knee-jerks were exaggerated. The gait was staggering, the patient walking with the feet wide apart. Vomiting unassociated with

Digitized by Google

the ingestion of food was present. The lesion appeared to be cerebellar, on the right side and low down. Dr. Purves Stewart pointed out that the headache might be due to the irritation of the fronto-cerebellar fibres crossing from the left frontal region to the superior cerebellar peduncle. The suggestion seemed a valuable one, and added a symptom of diagnostic value in the study of cerebellar disease. Mr. Annandale operated and removed a tumour from low down in the lateral lobe of the cerebellum, rather closer to the foramen magnum than to the outer wall of the skull The patient made an uninterrupted recovery and had since passed through a normal labour. Case 4: Infantile hemiplegia with convulsions. The skull was trephined, but nothing abnormal was found, and little benefit followed the operation. Case 5: A woman aged forty-seven years suffered from convulsive attacks. The intelligence was weak. She was believed to be suffering from dementia with a focus of irritation on the right side of the cortex. Dr. Cotterill performed an exploratory operation, but no gross lesion could be discovered. The patient died. Post mortem the brain was found to present the histological changes of general paralysis of the insane. Case 6: A man thirty-three months before admission had been injured by a plank falling on his head from a height of thirty feet. Since then he had spent most of his life in bed, suffering from occipital headache, giddiness, inability to walk, and deafness of the left ear. No spasmodic phenomena were present. There were on the head a scar and depression. Mr. Alexis Thomson removed with the wheel-saw an elongated section of bone, including the depression. Case 7: A man was admitted in a comatose state with twitchings of the right side of the face. On the following day he had a localised convulsion, commencing with the right side of the face and spreading to the arm and leg on the same side. This was repeated every ten minutes. Mr. Alexis Thomson operated and removed an extensive blood clot. Nine hours after operation the spasms ceased, but the patient sank and died. Post mortem a fissured fracture was found passing from the left parietal eminence to the middle fossa of the bone.—Dr. PURVES STEWART indicated the anatomical considerations which had led him to think that the frontal headache might be an evidence of cerebellar lesion, and he thought it might prove to be a new, a valuable means of differentiation.—Dr. W. RUSSELL said that the record of cases was such a record as was valuable to the profession, for it gave the whole experience of one man and was not confined to a few successful cases. It was records such as this that were wanted, not only in brain surgery but in the surgery of other regions.

ROYAL INSTITUTION.—The following are certain of the lecture arrangements before Easter: Dr. John Gray McKendrick, Professor of Physiology in the University of Glasgow, six lectures (adapted to a juvenile auditory) on Sound, Hearing, and Speech; Professor Charles Stewart, Fullerian Professor of Physiology, R.I., eleven lectures on the External Covering of Plants and Animals: its Structure and Functions; Mr. H. Marshall Ward, Professor of Botany in the University of Cambridge, three lectures on Some Aspects of Modern Botany; Lord Rayleigh, Professor of Natural Philosophy, R.I., six lectures on Light. The Friday evening meetings will begin on Jan 17th, when a discourse will be given by Lord Rayleigh on More about Argon. Succeeding discourses will probably be given by Professor Burdon Sanderson, Dr. John Murray, Dr. Edward Frankland, Professor T. R. Fraser, Professor Dewar, and other gentlemen.

DISINFECTING PLANT IN ISLINGTON. — The vestry of St. Mary, Islington, have lately invested in the erection of a very complete disinfecting plant and a shelter house for a family invaded by infectious disease. The cost of the station, which is in the middle of the Seven Sisters'-road, is roughly as follows: of two disinfectors, £500; of buildings, including shaft and laundry, £1100; of destructor, £85; of laundry appliances, £125. Besides, there is the cost of the shelter house, £1150. There is now no excuse in this parish for not being thorough in the disinfection of clothes, bedding, and other articles. This is a form of cremation of which all sensible ratepayers must approve. The station is found so useful that some neighbouring parishes contract for its use. Though the outlay may seem large, the cost of work is cheap compared with the old rates of disinfecting clothing, &c.

Reviews and Notices of Books.

Clinical Illustrations of the Diseases of the Fallopian Tubes and of Tubal Gestation. A Series of Drawings, with Descriptive Text and Histories of the Cases. By CHARLES J. CULLINGWORTH, M.D., Hon. D.C.L. Durh., F.R.C.P., Obstetric Physician to St. Thomas's Hospital, London; Examiner in Obstetric Medicine at the Victoria University; late Examiner at the University of London and the Royal College of Physicians, London; Hon. Fellow of the American Gynæcological Society, &c. London: Rivington, Percival, and Co., King-street, Covent-garden. 1895. Price 12*s.* 6*d.*

WE do not know that this work could have been subjected to a better test than that to which we have put it—namely, we have recently had occasion to refer to it in connexion with a case under treatment and have found it practically helpful. The author says that it has for some years been his intention to publish a series of illustrations of the diseases of the Fallopian tubes. The present work is the outcome of that intention. All the drawings are from specimens removed in the course of his own operative work; they are consequently taken from actual specimens, and are accompanied by a clinical history of each case, with the view of furnishing his readers with clearer ideas respecting tubal disease, and enabling them more fully to realise the processes actually taking place in such cases. We can only say that the drawings seem to us to be very useful and accurate delineations, some of the coloured ones being especially so, the artist having succeeded uncommonly well in producing effective pictures of morbid conditions which are true to nature. The author, alluding to the frontispiece representing the normal tubes as they are found in the living subject, takes the opportunity of making a few pertinent observations about this anatomical region. A good drawing of the parts contained in this region, as seen from behind in the healthy adult, affords information which is obviously an essential preliminary to a recognition of the anatomical changes induced by disease, and the frontispiece supplies this desideratum.

In addition to other illustrations there are altogether fourteen plates of a larger size illustrative of Hydro-salpinx, Purulent Salpingitis, Pyo-salpinx simulating Tubo-ovarian Disease, Hæmato-salpinx, Unruptured Tubal Gestation with Apoplexy of Ovum, Ruptured Tubal Gestation, and Primary Carcinoma of the Fallopian Tube. A descriptive text giving the clinical features of the cases in a very pertinent and brief way, together with a summary on Salpingitis and Tubal Gestation, complete the volume. We trust that we have said sufficient as to the nature and contents of this work and of its series of illustrations of the diseases of the Fallopian tubes to indicate its eminently useful and practical character and the opinion we entertain of its merits.

Guy's Hospital Reports. Vol. LI. 1894. Edited by C. E. PERRY, M.A., M.D., and W. H. A. JACOBSON, M.A., M.Ch. London: J. & A. Churchill. 1895.

THIS volume consists chiefly of a series of articles based on cases which have occurred in Guy's Hospital at various times. Mr. L. A. Dunn records the sequel of a case of Fractured Pelvis with Ruptured Urethra, which was reported in Vol. XLIV., and the same author gives an account of a case of Multiple Atrophying Sarcomata of the Head and Neck. An abstract of a paper by Mr. Bryant gives some interesting information concerning temperature after operations. Dr. Hale White and Dr. Chaning Pearce contribute a very interesting article on Empyema following Lobar Pneumonia. Notes and temperature charts are given of twenty-six cases which were treated in the

Digitized by Google

hospital between 1884 and 1894, inclusive, and the authors conclude that this complication has become more common now than in former times. Dr. John Fawcett has made a series of experiments with regard to the Efficiency of Piperazin in the Treatment of Gout, and does not think the drug so useful as many have supposed. Mr. F. Newland-Pedley writes two papers; one is on the Treatment of Suppuration of the Maxillary Antrum, and the other on the Treatment of Congenital Cleft Palate. Dr. Theodore Fisher gives an account of Some Researches into the Pathology of Hypertrophy of the Heart without Gross Organic Lesion. Mr. G. B. Smith discusses the question of Amputation in Senile Gangrene. Dr. Turner writes on Scarlatinal Nephritis and Dr. Silk on the Administration of Gas and Ether. Dr. Pye-Smith reports a case of Bilateral Paralysis of Facial and Auditory Nerves. A list of specimens lately added to the museum and the names of students who have passed examinations or received appointments end the volume, which is from first to last very interesting.

The Life of Sir Henry Halford. By WILLIAM MUNK, M.D. Leyden, F.R.C.P. Lond. London: Longmans and Co. 1895.

THE scholarly and accomplished librarian of the Royal College of Physicians of London has in this book set forth, at the express desire of the above-mentioned body, the life of one of the most celebrated of its members. Henry Vaughan, afterwards Halford, was the second son of James Vaughan, M.D., of Leicester, and was born in 1766. He was educated at Rugby and Christ Church, and from 1786 to 1789 studied medicine at Edinburgh. In 1792 he commenced practice at Scarborough, but at the end of that year started in London on a capital of £1000 borrowed from Lady Apreece, a friend and patient. In 1793 he was appointed physician to the Middlesex Hospital, and probably owing to his "Oxford connexions, his classical attainments, and his pleasing manners," was sworn physician extraordinary to the King before he was twenty-seven. In 1806 he gained great reputation by correctly diagnosing the disease from which the Duchess of Devonshire—Gainsborough's Duchess—was suffering, maintaining, in opposition to the whole of his colleagues, that she had hepatic abscess, and the accuracy of his diagnosis was proved by post-mortem examination. In 1809 he assumed the name of Halford on succeeding to the estate of Wistow and was created a baronet. In 1820 he was elected President of the Royal College of Physicians of London, a post he held until his death in 1844. We cannot here enter into all the details of his long career, of his close association with Royalty—he was physician to George III., George IV., William IV., and her present Most Gracious Majesty—of his services to the Royal College of Physicians, a body in which he took a most sincere interest: for all these the reader must refer to the pages of Dr. Munk's most interesting book.

As a picture of the manners of a bygone age the book is singularly faithful. Take the letter of the Royal College of Physicians in answer to the King's (George IV.) letter stating that the President of the College for the time being should always hold the office of physician in ordinary to the sovereign (pp. 104–5). We should have much liked to hear Thackeray's opinion of it. Again, take the letter of Sir Henry Halford and Sir William Knighton to George IV. dissuading him from attending the funeral of his father (pp. 175–6).

Sire,—We your Majesty's physicians venture humbly to approach your Majesty to implore your Majesty to forego that satisfaction to your feelings which your Majesty attaches to a performance of the last act of filial piety to the late King your Majesty's father. We are scarcely yet relieved from that state of anxiety and alarm which your Majesty's dangerous illness gave rise to and from which your Majesty is only just extricated under the mercy of heaven. We cannot therefore contemplate an indulgence of your Majesty's wishes without absolute dismay, seeing the probability of a relapse in consequence of the exposure of your Majesty's person to the night air in a cathedral, under that anguish of mind which your Majesty was observed by everybody so painfully to suffer at the performance of the same sad ceremony last year.

And we humbly entreat your Majesty to yield not to our wishes only but to those of the whole nation, which would be expressed, we are persuaded, if it were generally known that your Majesty meditated this dangerous effort of respect and piety. HENRY HALFORD.
WILLIAM KNIGHTON.

It seems unkind to remind a son of the satisfaction to his feelings at burying his father, and as the son was observed to suffer "anguish of mind at the same sad ceremony last year" we cannot see why he was so anxious to bury his father again. Well, well, "Sir George Catacomb had the confidence of his sovereign, sir," as Mrs. Frank Berry remarked upon a memorable occasion. With all his faults—and Dr. Munk does not disguise them—Sir Henry Halford seems to have been a capable physician, and, above all, a master of what perhaps we are too prone to forget now—the art of giving a patient ease and comfort as well as of treating the disease itself. Perhaps this book will take the place of that inscription in the Library of the Royal College of Physicians which that body unanimously decided in 1844 to put up, but for which the Library walls still sigh.

LIBRARY TABLE.

The Art of Horse-shoeing: a Manual for Farriers. By W. HUNTING, F.R.C.V.S. London: H. and W. Brown. 1895. Price 3*s.* 6*d.*—IF horses are not properly shod it cannot be because of any lack of directions as to how this necessary act should be performed, as the literature of the subject may now be described as superabundant. In this addition to it, which is professedly written for farriers—horse-shoers, it may be presumed, are meant, for veterinary surgeons are very commonly designated farriers, particularly so in rural districts—the old ground is gone over, and we find a *réchauffé* of the descriptions and directions which have been so often served up, perhaps with the view of making them more palatable each time. They are good so far as they go, because they are founded on common-sense notions of what is necessary to keep the horse's foot healthy and render the services of the animal more efficient and durable, and also because they have the results of a great many years' experience—some of them more than a century old—as evidence of their utility, although they have only too frequently been overlooked or ignored.

Elements of Human Physiology. By ERNEST H. STARLING, M.D. Lond. Second edition. Pp. 454. London: J. & A. Churchill. 1895. Price 7*s.* 6*d.*—This edition of Dr. Starling's useful little manual for the student of physiology has been carefully revised. The author has been prudent in not materially augmenting the size of the volume. What the beginner requires is not so much the newest theories but old and well ascertained facts arranged in due sequence and clearly explained. This work is one of the best of those which aim only at giving the student such a groundwork of physiological knowledge as will fit him to understand and guide him in the practice of medicine, without compelling him to wade through much irrelevant matter which would, perhaps, be serviceable to him if he were qualifying for a professorship.

London Temperance Hospital: Report on Surgical and Ophthalmic Cases for 1894. London: J. Vincent and Son. 1895.—This report is edited by Dr. Leonard Wilde and contains tabulated lists of the various cases which were treated in the hospital. The total number of surgical cases admitted in 1894 was 572, of which 95 were ophthalmic cases. Particulars of more important operations are given as well as abstracts of the pathological conditions in fatal cases.

Digitized by Google

There is also a full report of all the operations on the eye, with details of operations for extraction of hard cataract, from 1888 to 1894, inclusive. In the appendix it is stated that alcohol was not administered to any patient during 1894.

Cutaneous Medicine. Part I. By LOUIS A. DUHRING, M.D. Philadelphia and London: J. P. Lippincott Company. 1895.—This is a systematic work on Diseases of the Skin, which is intended to take the place of the author's "Practical Treatise on Diseases of the Skin," which is now out of print. An attempt is made in this new work to show the broad relations which the functions and diseases of the skin bear to the functions and diseases of the other systems of the body, and in so doing to give due attention to general diseases when local manifestations are the prominent symptoms. Part I. gives a good account of the general anatomy and physiology of the skin, and is made clearer by the presence of numerous excellent diagrams taken from many standard authors. The remainder of Part I. is taken up with general considerations regarding symptoms, etiology, pathology, diagnosis, treatment, and prognosis. There are numerous literary references throughout the work which add much to its value.

Hazelton: a Northumbrian Story. By Dr. WILLIAM MURRAY. Newcastle-on-Tyne: J. McCan.—It is well known that many of the busiest and most responsible members of the profession find their recreation in good novel-reading, and, indeed, that some of them are rather voracious in this respect; but few of them carry the recreation to the further point of writing novels. An instance to the contrary is before us in the shape of a very readable and commendably short novel by Dr. William Murray. "Hazelton, a Northumbrian Story," is redolent of that region, with the fine salmon-fishing rivers of the North Tyne, the Cheviot Hills, and other characteristic scenery. Dr. Murray displays a familiarity with the life of the natives in every grade of society, from the gamekeeper to the squire and the lord. He treats of young ladies and gentlemen in the perplexity of the love period of their lives and the perplexities of their suitors, together with the troubles of their seniors over other and deeper problems which make the interest of good novels. He writes on such subjects as easily as if he had written on them before, or should have done so, and out of the experience which an observing physician has of human life. We commend the story to our readers as one thoroughly sound in its tone and very readable—characteristics constituting great charms in such literature. The Northumbrian dialect may at first sight be a slight stumbling-block to some readers; but Dr. Murray renders it accurately as one to the manner born and guides us safely through the most difficult passages.

Contribution à l'Étude de l'Atrophie Musculaire Progressive, type Duchenne-Aran. Par le Dr. J. B. CHARCOT, Ancien Interne des Hôpitaux. Paris: Félix Alcan. 1895. (*Contribution to the Study of Progressive Muscular Atrophy, type of Duchenne-Aran.* By Dr. J. B. CHARCOT.)—This essay, the first literary venture of its author, is dedicated by him to the memory of his illustrious father. In the thoroughness and fidelity with which the task is executed, and the clearness with which the thesis is expounded, we recognise that the son has inherited those gifts of intellect which have made the name of Charcot world-famous. The aim of his present contribution to science is to re-establish as a distinct clinical and pathological entity that disease with which the names of Duchenne and Aran are indissolubly associated. Twenty years ago "progressive muscular atrophy" was an affection which figured prominently in the nosology, and the connexion of which with degeneration of the anterior cornua of the spinal cord was regarded as a leading example of the trophic influence of the nerve cells of that region. But the advance of neurology led to a remarkable disintegration of the affections included under the common term, and no work did more to this purpose than the demonstration by Professor Charcot himself of the fact that many a case was really due to secondary involvement of the grey matter in a sclerosis originating in the lateral columns. The study of multiple neuritis, of syringomyelia, and of primary myopathic atrophies still further reduced the domain of chronic anterior poliomyelitis, so that not a few of the most distinguished neurologists openly declared that it had no independent existence. Even Professor Charcot himself, his son informs us, was somewhat shaken in his belief in the existence of a protopathic spinal amyotrophy by finding in later years that cases which he had previously considered to be of this order were really of the nature of syringomyelia. Dr. J. B. Charcot, however, produces in this essay arguments and facts which tend in the other direction. He gives a full record of five cases personally observed in the Salpêtrière Hospital, two of which are completed by details of post-mortem examination; and he concludes that the Duchenne-Aran type of progressive muscular atrophy is a morbid entity absolutely distinct from amyotrophic lateral sclerosis. To be sure, he points out that accompanying the nerve-cell degeneration in the anterior cornua there is a zone of sclerosis in the direct pyramidal tract, but he regards this latter, quite reasonably, as being immediately dependent upon the nerve cell lesions. As we have said, the essay is lucidly written and its reasoning well sustained. It is further illustrated by some excellent pathological drawings. We trust that it will prove to be the forerunner of many important contributions to neurology from the same pen.

CHRISTMAS BOOKS.

Messrs. Blackie and Son send us, besides those we mentioned in our issue of Dec. 7th, the following books:

Through Russian Snows: a Story of Napoleon's Retreat from Moscow. By G. A. HENTY.—*A Knight of the White Cross: a Tale of the Siege of Rhodes.* By G. A. HENTY.—Mr. Henty has the faculty of really interesting boys (and many girls too), and he has told his story of Napoleon's retreat from Moscow with such spirit that it is one of the best he has written. It is the story of two boys who were left orphans, one of whom, after being taken prisoner for alleged smuggling and a suspicion of murder, volunteered for the French army on the condition that he would not be required to fight against the English; and the other, holding a commission in the English army, was offered an appointment on the staff of a Russian General on account of his knowledge of the Russian language. They both went through the Franco-Russian war of the first Napoleon and finally met at the conclusion of the campaign. The second story deals with the struggle between Christianity and Mahomedanism and the great part played by the Order of the Knights of St. John against the Turks. The story, which is well told, deals with the first siege of Rhodes, in which the author has no difficulty in finding plenty of incident and excitement to sustain the interest of his readers.

A Thane of Wessex. By C. W. WHISTLER.—This is a well told story, which, although written in a professedly archaic style, does not bore the reader as many modern archaisms do. The subject is the great Viking raid of 845, and tells how Heregar was outlawed on a false accusation of treason. He discovered the war ships of the Vikings, gave warning to his countrymen, and finally by strategy defeated the Danes at the mouth of the Parret, and was thereupon taken into favour again. The account of the battle is quite Homeric in its force and simplicity. Mr. W. H. Margetson's illustrations are good although anachronistic. We are sure

Digitized by Google

there was not any Norman architecture at Glastonbury in 845, nor do we think that the habit of a Benedictine nun in those days was white.

At War with Pontiac. By KIRK MUNROE.—This is a capital story of Indian warfare in America. The hero passes successfully through some thrilling a ventures, being protected by a tattoo mark of the Bear Totem. He finally marries the daughter of Pontiac, the great chief, she being an eighteenth-century Pocahontas, but, luckier than her prototype, she lives happily with the man whose life she saved.

The Tiger of Mysore. By G. A. HENTY.—Any book about India ought to be interesting to English boys, and doubly so when written by such a good story-teller as Mr. Henty. "The Tiger of Mysore" is a tale of the times of Tippoo Saib; the adventures of Dick Holland in the attempt to rescue his father—an enthralling scene with the Tiger in the harem—and the escape from the hill fort being two episodes which stand out among a number of others.

Mr. T. Fisher Unwin sends us:

Dog Stories from the "Spectator." With an Introduction by J. ST. LOE STRACHEY. — This volume consists of selections from the correspondence columns of the *Spectator* descriptive of the intelligence, reasoning power, and sympathy of dogs. The selections are both good and interesting. All of us are fond of animals, boys and girls especially so, we are glad to say, for there is nothing more natural, wholesome, or beneficial than the cultivation of the humane and sympathetic sides of our natures. All who have read the letters that have appeared from time to time in our contemporary will be glad to renew their acquaintance with them in a collected form, and those who have not done so will peruse this volume with a fresh and lively interest.

Among the Gnomes. By FRANCIS HARTMANN, M.D.—The book is a far-off following of Peacock's satires, and though well done in places is, on the whole, heavy.

The Chain of Gold, by STANDISH O'GRADY, is an admirable tale of the adventures of two boys on the wild west coast of Ireland. The shifts to which the castaways are put and their ingenuity in overcoming them are vividly told, and the slight admixture of the supernatural in the story is quite in keeping with the Celtic spirit.

Stories for Ten-Year-Olds. By FRANCIS WILCE SAUNDERS. Series I. London: Swan Sonnenschein and Co. 1895. 2*s.* 6*d.*—We think these little sketches and stories are better suited to those who are over than under ten years of age. Many of them are no doubt clever and suggestive, but to be fully appreciated they seem to us to require a sense of humour and a power of reading between the lines which boys and girls often do not possess, and the style and language are not sufficiently clear, simple, and direct.

DECEMBER JOURNALS AND MAGAZINES.

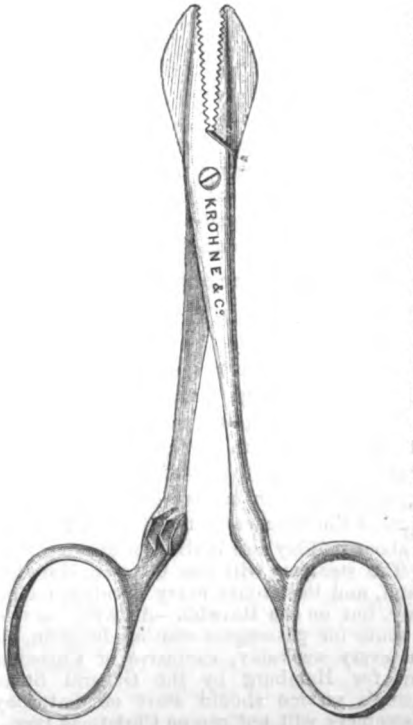
The Medical Chronicle.—Dr. D. J. Leech contributes his paper on "Our Forefathers" which was read at the opening session of the Yorkshire Medical College on Oct. 1st, 1895, and an abstract of which was printed in our issue of Oct. 5th. Dr. Kelynack publishes an interesting series of cases showing the Connexion between Alcoholic Neuritis and Pulmonary Tuberculosis. Mr. E. H. Howlett contributes Notes of a Case of Tetanus following a Gunshot Wound successfully treated with Tetanus Antitoxin.

The American Journal of the Medical Sciences.—Among the many good papers in this periodical are Dr. William Osler's dealing with the Visceral Complications of Exudative Erythema, and Dr. R. T. Hall's upon Craniotomy for Epilepsy. Dr. Louis Starr gives a series of cases of Scurvy occurring in children fed upon sterilised milk.

The Practitioner.—Dr. R. T. Hewlett has an admirable paper upon Antitoxin Treatment.

New Inventions.

A BASIN ENEMA CLIP.

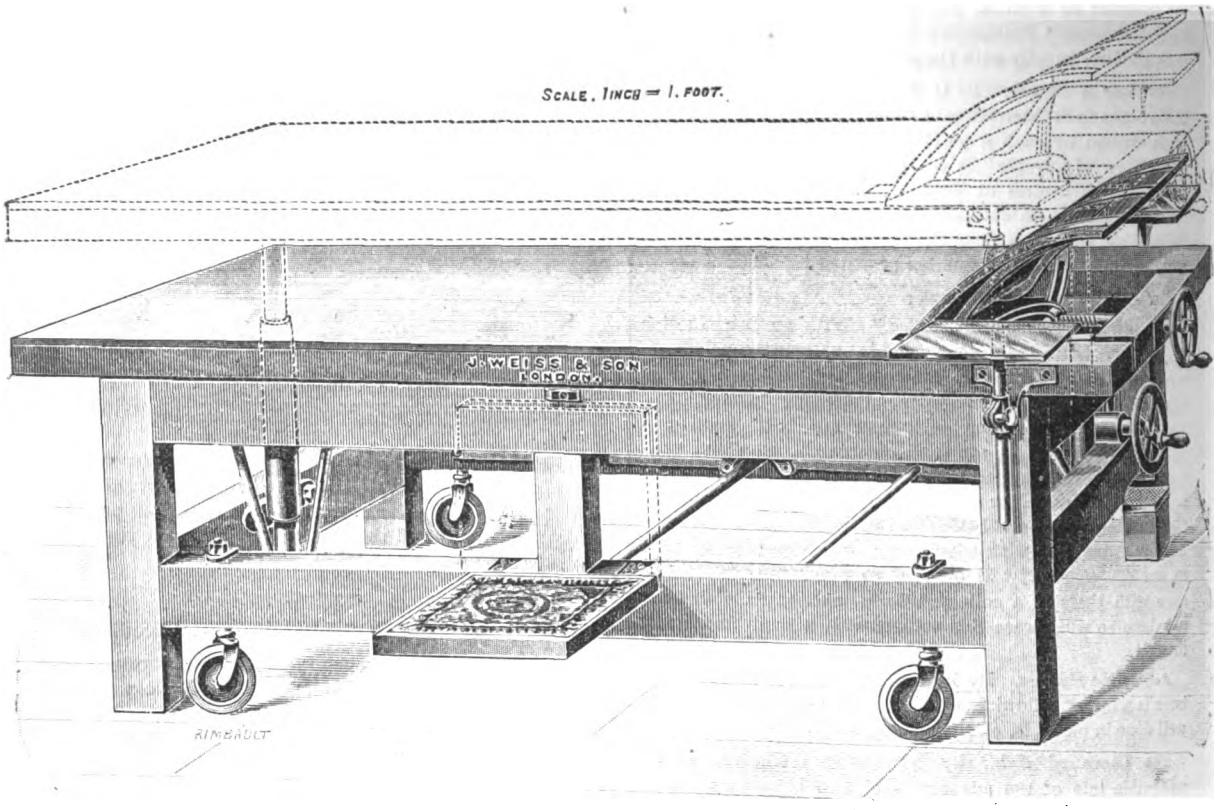


MESSRS. REYNOLDS AND BRANSON, 13, Briggate, Leeds, have sent us an ingenious and useful little appliance, one which will be a real convenience to medical men and nurses. The clip will hold the tail of any enema syringe firmly at the bottom of the basin, beneath the liquid, making the entrance of air impossible. It also has another very great

advantage in acting as a rest for the bone rectal (or vaginal) pipe after the enema has been used, and so avoiding the wetting of bed linen or making a mess on the floor or table. The illustration shows the clip at one-third its size. The price is 6*d.* (post-free 7*d.*), or 5*s.* per dozen.

IMPROVED CLIP FOR LIGATURING VESSELS.

THERE is often some difficulty in ligaturing vessels over the ordinary Spencer Wells'clip, especially in deep wounds. Either the point of the instrument is included in the ligature, or in trying to avoid this the clip is torn off the vessel. In the modification shown in the illustration I have tried to combine the convenience of a tenaculum with the advantages of forci-pressure. A thin, curved flange projects from the blades of the clip in the plane of the handles and guides the ligature over the point. In other respects the clip is unaltered. Frequent trials (for which I have to thank the surgeons of St. George's Hospital) have shown that the instrument works well. The slight widening of the blades seems to involve no practical inconvenience. I am indebted to Messrs. Krohne and Co., of Duke-street, Manchester-square, for the great trouble they have taken in working out the idea.



ARTHUR H. WARD, F.R.C.S.Eng.,
Surgeon, London Lock Hospital; Surgical Registrar, St. George's Hospital.
Hertford-street, W.

TABLE SPECIALLY DESIGNED FOR OPHTHALMIC OPERATIONS.

IN accordance with instructions prepared by the medical staff of the Royal London Ophthalmic Hospital, Moorfields, Messrs. John Weiss and Son, 287, Oxford-street, W., have designed and made a new table for the operating-theatre, having the following among other advantages—viz.: The top of the table is of solid mahogany, 6 ft. by 2 ft., which, together with the frame, can be raised ten inches by means of suitable gearing worked by a hand-wheel, the minimum height being 2 ft. and the maximum 2 ft. 10 in. from the ground. The table is perfectly firm whatever be the level of the top. The leverage is such that the top of the table carrying a heavy man can be easily raised by turning the wheel with one hand alone. The headpiece, on being raised by a screw action, takes the form of a pillow the height of which is adjustable. By means of a foot lever the table can be lifted off its legs on to rubber-tyred wheels to facilitate the movement of the table from place to place with or without its burden. Each side of the table has an adjustable support to carry the instrument trays, &c., also a step to allow of the patient reaching the floor without the height being altered.

CHRISTMAS HOLIDAYS.—The Hook of Holland route of the Great Eastern Railway Company offers exceptional facilities to persons who wish to spend their Christmas holidays in Holland or Germany. Passengers from the midland counties or north of England can travel direct to Parkeston Quay, Harwich, and with the passengers leaving London in the evening arrive at the chief Dutch cities the following morning, while through carriages run to Cologne and Berlin on arrival of the steamers at the Hook of Holland, reaching Cologne about midday and Berlin the evening after leaving London. The steamers will run between Harwich, the Hook of Holland, and Rotterdam every evening, including Christmas Day, but on the Harwich—Antwerp service, which is the best route for passengers visiting Belgium, the steamers will run every week-day, exclusive of Christmas Day. Passengers for Hamburg by the General Steam Navigation Company's service should start on Saturday, Dec. 21st, as the steamers will not run on Christmas Day.—The London and North-Western Company announce that the ticket offices at Euston, Broad-street, Kensington, and Willesden Junction will be open throughout the day from Monday, Dec. 16th, to Monday, Dec. 23rd, inclusive, so that passengers wishing to obtain tickets for any destination on the London and North-Western Railway can do so at any time of the day prior to the starting of the train. Tickets dated to suit the convenience of passengers can be obtained at any time (Sundays and Bank Holidays excepted) at the town receiving offices of the company. On Tuesday, Dec. 24th, a special train will leave Willesden Junction at 2.55 P.M. for Bletchley, Wolverton, Rugby, principal stations on the Trent Valley line, and Stafford in advance of the 2.45 P.M. ordinary train from London (Euston). The 4.30 P.M., Euston to Birmingham, will be divided; the first portion will run express to Coventry and Birmingham, and leave Euston at 4.25 P.M.; the second portion of the train will leave Euston at 4.30 P.M. as usual. The night Irish mail, due to leave Euston at 8.20 P.M., will not leave until 9.5 P.M. The mail steamer for Kingstown will await the arrival of the train at Holyhead. On Christmas Day a special train will leave Euston at 6.15 A.M. for Northampton, Rugby, Birmingham, Stafford, Stoke, Crewe, Manchester, Liverpool, Chester, Ireland, Lancaster, Preston, Carlisle, Edinburgh, Glasgow, &c. The company also announce cheap excursions to Coventry, Leamington, Birmingham, South Staffordshire stations, Wolverhampton, Nuneaton, Liverpool, Warrington, Lancaster, the English Lake District, Manchester, Oldham, Stoke, Chester, North and South Wales, and the Cambrian line, Shrewsbury, Carlisle, Scotland, Ireland, &c.

THE LANCET.

LONDON: SATURDAY, DECEMBER 14, 1895.

THE limits of a medical man's duty to the dependent classes form a subject of great interest and importance, and this has been well handled in an able article by Dr. JAMES WALK in a paper read before the American Academy of Medicine at Baltimore on May 4th of this year. It is obvious that our American *confrères* suffer as severely as we do from over-competition and crowding of professional men, and especially from unjust imposition of gratuitous work. The medical student of to-day has the greater part of his training devoted to the physical sciences. In former times the tyro engaged in professional visits with his preceptor and acquired not only remedial science but the methods of dealing with men and women in their moral, social, and business aspects. The ordinary medical charities, crowded with patients, are not the only outlets for the superabundant philanthropy of the young physician or surgeon. It is a growing notion that the medical man should treat free of charge all the dependents of his neighbourhood. Upwards of 20 per cent. of the population of Philadelphia receive free medical treatment. In the crowded out-patient departments of dispensaries and hospitals what opportunity is there for that careful and systematic investigation of cases which alone is of true clinical value? The wholesale system of gratuitous medical relief pauperises the community. The younger medical men are defrauded of their share in practice, and the whole profession is injured and degraded. The enormity of the evil may lead to a powerful revulsion of feeling, within and without the profession. The article, written in a moderate tone, certainly does not show an encouraging aspect of affairs in America. Any candid observer must assert that in our own country, especially in the large towns and centres of civilisation, matters are little better, though we have good reason to believe that in this country the "special hospitals" are perhaps the most abused.

It is a lamentable fact that the training of many a modern scientific student does little to fit him for the practical duties of his profession, especially in its business aspects. The advice not uncommonly given by senior members of the profession to juniors just emerged as fully fledged practitioners is somewhat as follows: "Now you have passed your examinations, go and learn your profession by acting as assistant." Be this as it may, many young consultants and practitioners are strangely deficient in even that rudimentary business capacity which would be essential towards the successful conduct of any other occupation or profession. The enthusiastic physician or surgeon who occupies years of his life in crowded out-patient departments will assuredly waste his time unless he turns his opportunities for the investigation of disease to account. The crowds of patients, as well as the deficient accommodation, not uncommonly quite prevent this. Of the scores of individuals who occupy his time, and who dub him by the suggestive epithet of the "free doctor," not a few, if closely questioned, would be found to be well able to pay the customary fee for consultation. We do not believe that matters are quite as bad in this country as in America; anyone, however, who perused the addresses of representative practitioners in the ethical section at the recent meeting of the British Medical Association could not fail to be struck with the serious tone which pervaded many of the sentiments uttered regarding such matters as hospital abuse and club practice. The evil is already "sufficiently enormous" in this country to call for the most serious attention on the part of all the younger members of the profession. As regards the matter of hospital abuse, this lies almost entirely in the hands of the profession itself. In this connexion we may recall to our readers the valuable paper of Messrs. GRIFFITHS and HORDER, published in our issue of Nov. 30th. The paper embodied the results of an elaborate inquiry undertaken by these gentlemen into the matter of abuse of medical charities and contains a number of most practical suggestions. We cannot commend the wisdom or *savoir faire* of any consultant who gratuitously gives away his services at a hospital to a patient who can pay him a fee. We do not altogether think well of the medical or business capacity of any family practitioner who allows his patient to drift to a hospital through his tardiness in suggesting a consultation; still less do we approve of the custom, which is alleged to be gaining ground in London, of practitioners sending their patients to hospitals to obtain gratuitous opinions. It is almost an established fact that three-fourths of the accident practice in London is done gratuitously at the hospitals. While no one can be refused first aid at a hospital, be he peer or be he pauper, we would most earnestly urge the surgeons of hospitals situated in fashionable localities of large towns to exercise very close supervision in this matter. So soon as a simple fracture has united, or is safely placed in retentive apparatus, the patient should be dismissed to his own house under the care of his own medical man, or to one of the many excellent private institutions which exist for care and nursing. There is little reason why such cases as wounds of the radial artery or fractures of the bones of the upper extremity, after receiving the immediate aid which they demand, should not at once be consigned to the care of the patient's own medical man, who in his turn may ask the consultative advice of any surgeon he chooses. To treat cases of this nature in well-to-do persons gratuitously is the worst form of hospital abuse. All the junior officers of large hospitals, especially the house surgeons, should be instructed to see into each case and report on it in writing to the secretary of the hospital or other responsible officer. Practitioners in the neighbourhood of a hospital would confer a great boon upon the profession if they reported to the secretaries any cases coming under their cognisance where their patients are abusing the purposes of charitable institutions. We hope that consultants at the hospitals will take these remarks, which are offered in no captious spirit, seriously to heart. We trust also that practitioners will coöperate with them in the duties of self-protection. The hour has arrived when members of our profession should cease to give their time and labour to those who, although they

Digitized by Google

can find money for the theatre or a trip to the seaside, go to a hospital when they are ill. Such persons, who are numerous enough in London as well as Philadelphia, usually take a professional man at his own value and, on one pretence or another, are constantly emulating the daughters of the horse-leech and crying, "Give, give!" So far as teaching opportunities go, benefit would certainly be conferred upon the hospitals by limiting the number of out-patients, and at certain well-known institutions this has already been done. Sufficient material can readily be found among the ranks of the really poor, who alone should share the benefits of charitable funds.

We note with satisfaction that one of our large London hospitals has recently increased its teaching staff—an example which may be well followed by others. If, in addition to increasing the care and facilities in teaching, the medical officers of our hospitals would once and for all set their faces against gratuitous relief to those who have means, they would be helping a reform which could not fail to meet with all support from the rank and file of the profession, and with the approbation of the right-minded section of the public, who would recognise that their charitable bequests were not wrongly used. The growing generation of students would learn a useful and lasting lesson—viz., that, though kindness and philanthropy should ever be practised by every medical man, he should most jealously guard against abuse in these particulars and exemplify throughout his life the adage that every man has a right to expect and receive adequate pecuniary reward for his labours.

To the question what shall we drink, to discuss which at this season of the year seems a little odd, Mr. RADCLIFFE COOKE in the *Times* of the 9th inst., backed by a leading article in the same issue, would reply, cider. With the economic and industrial aspect of the question, which is a very important consideration, we have little to do beyond expressing our entire approval of any movement that is calculated to warm into life and vigour a well-nigh extinct home industry. We turn, then, to consider what are the qualities and special characteristics of cider upon which its recommendation as a popular drink could be based. In this connexion there is little doubt that cider has not been very favourably regarded, because no special care or attention has been paid by cider makers to the exact conditions which would ensure the production from the apple of a uniform and palatable drink. The use of materials that are chosen with little regard to their quality—as, for example, damaged fruit, or fruit looked upon as of no good for any other purpose than cider making—has operated largely against its taking rank on any extensive scale with other better-known beverages. The process of fermentation has hitherto been conducted in a slipshod, rule-of-thumb way, without regard being given to the minutiæ of the process. What wonder, then, that cider has not been popular except amongst a few country people in those counties where it is chiefly produced. Yet there is no reason at all why there should be any uncertainty as to the ultimate condition of cider, any more than there should be of beer or claret. The composition of good cider is not widely different from light claret, except that instead of tartrates and tartaric acid it contains malates and malic acid, the characteristic acid of most fruits, and the proportion of spirit is less.

The average composition of still cider is as follows: 4·88 per cent. alcohol, 0·33 per cent. malic acid, 1 per cent. acetic acid, 4 per cent. sugar; of champagne and effervescing cider, 3·5 per cent. alcohol, 0·35 malic acid, 0·05 acetic acid, 6 per cent. sugar; of bottled Hereford cider, 5 per cent. alcohol, 0·3 per cent. malic acid, 0·1 per cent. acetic acid, 1 per cent. sugar. The latter may be described, like some champagnes, as dry. Success in the making of cider is favoured also by carrying on the process of fermentation like that of lager beer at a moderately low temperature, when the sugar is rapidly converted into alcohol and carbonic acid. Otherwise, if the alcohol be slowly produced, organisms rapidly make their appearance, producing acetous and possibly also lactous fermentation. These are the enemies of the cider-maker, and of course fatal to the production of a palatable drink. It is worthy of remark that the alcohol of well-made cider is, owing probably to the low temperature employed, particularly pure, and on distillation yields a spirit of excellent character and from which very good brandy may be made. It is free from other alcohols and allied products, which doubtless contribute to the stupefying and heavy qualities of strong English beers brewed at comparatively high temperatures. This alone is a fact in favour of cider as a beverage. The fruit acid of cider, however, is not thrown out of solution as the alcohol increases, as is the case with certain wines. The delicate flavour and agreeable fruity aroma of unsophisticated cider are due to the extraction of the essential oils of the pips and skins of the fruit by the alcohol produced, the alcohol itself being rich in compound ethers. It is to malic acid that cider owes its pleasant acidity, and the presence as well of alkaline salts and malates (which produce alkaline salts) gives cider its diuretic and slightly aperient properties. On this account cider would seem to be a useful beverage for the gouty and those who suffer from uric acid deposits, the expulsion of which it is said to favour. But for this purpose, as, indeed, for general purposes, the cider must be sound. If sound and genuine cider be placed upon the market with a guarantee we make no doubt that the demand for it will rapidly increase, and when the public once find out for themselves the really wholesome and refreshing qualities of genuine cider the nasty preparation purporting to be cider will be banished, a home industry will be restored to the position it ought never to have lost, and an agreeable and mildly stimulating beverage will be available which, if consumed rationally, will be found free from the objectionable qualities of many beverages that unfortunately are only too highly held in popular esteem. Sound cider, on the other hand, should possess to an equal degree the refreshing and harmlessly exhilarating properties of genuine light grape wines, the consumption of which abroad, to the exclusion of ardent spirits, has had a distinctly healthy and moral effect upon the people.

WE are sorry for the managers of the Metropolitan Asylums Board. A task at once impossible and ungracious

Digitized by Google

has been assigned to them, and they are getting that plentiful blame which awaits gentlemen in our happy country who undertake such tasks without fee or reward. All sorts of faults are attributed to them. They do not supply an amount of accommodation for infectious cases equal to the demand; they dismiss, or their medical officers dismiss, cases before they are free from infection, and thus give rise to fresh cases of the very diseases for the restriction of which they were elected. They spend money like water to the figure perhaps of half a million a year, and one of their own number has been unkind enough to suggest that some members of the Board, or of its committees, pay ridiculously large prices for sites, and that there is a suspicion of personal profit and advantage in the transactions. We may say at the outset that we have little belief in the truth of these suggestions. It is undoubtedly tempting to men dealing with such large sums of public money and with contracts of such magnitude—and knowing also the difficulty which the Board has in finding a local habitation for its unpopular hospitals—to turn to personal advantage circumstances of which they have early or exclusive knowledge. But, fortunately, in both Imperial and Local administration there has always been amongst us an abundant supply of men of ability and standing who were "above suspicion." And until the contrary is shown by very much more evidence than Mr. ELLIOTT has produced, we shall have implicit confidence in the integrity of the managers of the Metropolitan Asylums Board. Sir EDWIN GALSWORTHY dealt admirably with Mr. ELLIOTT'S suggestions and his demand for an inquiry. He refused to be content with any inquiry by a committee of the Board, and moved an amendment for investigation by the Local Government Board. This was a dignified course, and one that will be entirely satisfactory to the public.

This was by far the least interesting part of the business before the Board at its meeting on Saturday last. The great interest of the meeting was in the complaints from all quarters of the inadequacy of the accommodation provided by the Board, and the pressure put on it to open Gore Farm—now used for small-pox cases—for fever patients. The feeling of dissatisfaction on this subject will scarcely be allayed by the hopeful view of the chairman, founded chiefly on one day's experience, that the decline of the epidemic had set in. Though every application for admission that day—the day of meeting—had been met, the number of cases of fever and diphtheria treated in the hospitals in the last fortnight had been 3562, against 3551 in the previous fortnight. We have no doubt that the complaints from all quarters—from Lewisham, St. Pancras, Bethnal-green, Limehouse, and other boards—are well founded, and we see little reason to hope for any immediate relief or remedy if the present absurd facilities for entering these hospitals by the public are allowed to continue. It is one thing to provide isolation hospitals for the poor or for those who had no adequate accommodation in their homes. It is quite another to invite the public into such hospitals as Parliament has done. We have the greatest misgiving as to the justice or the wisdom of this policy. But it was passed with a light mind by Parliament in 1890, and it is the chief cause of the insuperable difficulties into which the Board has been brought. The representative of the *St. James's Gazette* satisfied himself, on statistical evidence furnished him at Norfolk House, that prior to the new legislation which admitted the public—as distinguished from the poor—to the hospitals of the Board the accommodation was ample, and that this legislation led to a sudden and overwhelming increase in the applications for admission. This is what we have always suspected. The Hon. SYDNEY HOLLAND says, in a letter to the same journal that "if the Board did what it ought to do—provide accommodation for every case of scarlet fever or other infectious disease of like moment in London—it would probably mean the expenditure of a million of money. And what would the ratepayers say to that?" We should say that it would probably mean the expenditure of many millions. That might be a superable objection, for the poor ratepayer is soon silenced. But the wisdom of the policy seems so doubtful that it should not be persisted in till a full investigation of the working of the present system of admission has taken place. Let the public realise that there are hundreds, if not thousands, of cases which can be isolated and treated at home, and which ought to be so treated. The causes of the prevalence of infectious disease need immediate and close investigation.

It is a little disappointing to see a man in Mr. HOLLAND'S position, as chairman of a charitable hospital, say, even with some qualification, "that the Board ought to provide accommodation for every scarlet fever case and other infectious diseases of like moment in London." We should have expected some clearer exposition of the enormous difficulties and cost of such a policy, and some insistence on the duty of all people who can treat their infectious cases at home to do so. We do not blame the hospitals of the Board for the spread of infectious disease. The authorities have shown that the "return" cases which arise from patients prematurely dismissed are not many, and that they keep scarlet fever cases on an average ten weeks and diphtheria cases seven weeks. All the same, it is obvious that there is no obligation on the State to provide isolation for those who can have it in their own homes, and that the loose legislation of 1890 has excluded those for whom isolation hospitals are urgently demanded on every ground of humanity and policy. This matter is urgent, but the most urgent matter of all, and the shortest way to find accommodation for the really proper cases in the hospitals of the Board, is to create safeguards against the use of the hospitals by those who do not need them.

SURGICAL AID SOCIETY.—The annual meeting of the Surgical Aid Society was held at the Cannon-street Hotel on Dec. 9th, the Lord Mayor presiding. The report which was read by the secretary, Mr. R. C. Tresidder, showed that during the year 13,345 patients had been relieved, including 4842 men, 6961 women, and 1542 children. There had been a considerable increase both in the amount of relief afforded and in the number of surgical appliances granted to poor applicants, no fewer than 20,046 such articles having been supplied. The income during the last twelve months had been £10,599 as against £10,256 in the preceding year. The Lord Mayor said that the society had been established thirty-three years, and during that period had supplied 220,600 surgical appliances to needy sufferers.

Annotations.

"Ne quid nimis."

LONDON WATER SUPPLY.

IN conformity with a resolution of the County Council, made on Oct. 22nd, "That the Council having decided not to proceed with the suspended water Bills, and desiring that the Council should be the water authority for London, it be referred to the Parliamentary Committee to report to the Council without delay the lines on which the Government should be asked to legislate," the Parliamentary Committee presented their report at the last meeting of the Council on the 10th inst. It is a very lengthy report, and embodies every phase of the question previously before the water committee. It points out that if the water companies' undertakings were purchased on ordinary arbitration terms London might be made to pay from thirty to forty millions in purchasing the undertakings, and find itself obliged to spend in addition from ten to twenty millions in providing a new supply. In explanation of their action in recommending the Council to invite the Government to deal with the question, the committee point out that the county of London over which the Council desire to be the water authority is only one-seventh of the area the requirements of which the Royal Commission of 1893 said would have to be considered. The Government should, therefore, be asked to constitute by Act of Parliament a public authority for the whole water area, and they suggest taking as a basis the proposal made by a select committee, of which Sir William Harcourt was chairman, that a body be composed of members nominated by the London County Council, the City Corporation, and the home counties, with the addition of nominees of the Local Government Board, and of a sufficient number of coöpted members possessing special knowledge and qualifications. The Act should confer upon the water authority thus constituted full power to purchase the undertaking of all or any of the companies by agreement, and, failing agreement, to determine in what manner and on what conditions purchase shall be effected. The committee observe that no serious attempt has hitherto been made by the Council to negotiate with the companies, and they think that every consideration now points to the desirability of this course being taken without delay. In the event of a purchase not being effected an inquiry into the statutory powers and obligations of the company and the control exercised over them, with a view to make these obligations, &c., more complete, should be instituted; but pending the formation of the water authority the committee suggest that the Council could usefully take steps with a view to facilitating the acquisition of the companies' undertakings. In regard to future supply, the water committee should, they think, bring up its report with the least possible delay. This report only came formally before the Council on Tuesday last, its consideration being adjourned till next week. There will be, therefore, considerable interest attaching to the proceedings of the next meeting.

GEORGE AUGUSTUS SALA.

DURING his forty years of journalistic exertion it would be strange if, among the innumerable topics he took up and laid down the better for his handling, Mr. Sala did not have frequent occasion to touch on the healing art and its practitioners. We know, in fact, that he took special pleasure in watching the fight between medicine and disease, in recording the victories won, or, even when these were indecisive, in noting such advantages as were gained by the hygienic or therapeutic arms. In the columns of the influential and widely diffused journal with which he was connected we can recall many a brilliant article, dwelling on discoveries or incidents attesting the advance of medicine—recall it (let us add) with the more pleasure that it was THE LANCET from which such texts for the day were usually drawn. During the great battle commenced in these columns thirty years ago for Poor-law amelioration, in which the late Drs. Anstie and Netten Radcliffe bore a conspicuous part, we often recognised with gratification the effect our arguments and revelations produced on the lay journalist—on none more than on Mr. Sala, who popularised them and diffused them over an area of the reading public which THE LANCET by itself could not have reached. And as with great questions of social reform so it was with topics of individual or restricted, but striking, medical interest. Some twenty-two years ago, when a "Howard commemoration" was a subject of the day, his leading article on that mighty philanthropist was perhaps the best tribute to him the occasion evoked, recalling in some of its passages the memorable eulogy by Edmund Burke. Again, in his frequent excursions to this or that great European capital—"working-holidays" he used to call them—he rarely omitted to note the standard reached or missed in philanthropic effort or social amelioration. In Rome, for example, he presided at a meeting in aid of the Victoria Home for the rescue and rehabilitation, under British and American auspices, of the little waifs and strays of the Eternal City, and his eloquent, kindly, and touchingly humanitarian appeal was of signal service to the friends of the institution. In the same city or rather its neighbourhood he interested himself in the reclamation of the Campagna by the Trappist brothers at the Trefontane, and his picturesque account of their success won him the gratitude of the devoted men, employed in that all too inadequately supported work. We might multiply instances of his essentially humane and generous nature from our recollection of his coöperation in medical charities, especially in the organisation of the Hospital Sunday movement; but we have said enough, as medical journalists, to warrant our contribution to the mass of testimony borne in his honour by those of other interests—the literary, the dramatic, and the artistic. A conspicuous and popular figure in the public life of the Victorian era, George Augustus Sala will be remembered, long after individual attestation can make itself heard, not only as a humourist and *raconteur* and an accomplished man of letters, but, in the language of Heine, as "a brilliant swordsman in the struggle for the liberation of humanity."

MEDICAL DEFENCE AND QUACKS.

WE are very glad to see that the Medical Defence Union has succeeded in obtaining a conviction against a person named Ferdinand who, besides misrepresenting himself to the general public with regard to his degrees, is also the author of some of the most disgusting and disgraceful advertisements that we have ever seen. The advertisements are written in order to promote the sale of a patent medicine called "ferlandi," which, of course, is a panacea for all diseases under the sun "except rupture and bad cases of cancer, which require special treatment," and this, as we are told later on, consists in the latter case of "ferlandi" combined with cancer pills. Hospitals are designated by the delicate name of "carving saloons," and the public are asked whether these "carving dens are to continue" and whether those who practise in them are to be allowed to associate with respectable people. It is a pity that this contemptible individual does not give us his own definition of respectability, as we imagine it would have to be rather a sweeping and ingenious one if it

Digitized by Google

is to include him in it. The advertisements, however, have their interest, as, in order to prove that hospitals deserve the name of "carving saloons" and other such genteel epithets, many of the same cases are quoted as those which anti-vivisectionists bring forward in support of their allegations. In both cases the method of quotation is the same; fragments of cases are given which would in most instances appear in quite a different light if their full particulars were set out. We cannot do better than conclude with one of Ferdinand's own prayers: "From all quacks and speculators, good Lord, deliver us, our children, and our pets."

ERRORS IN DIAGNOSIS.

THE difficulty which exists in making an accurate diagnosis of many injuries to the head has again been shown at the Vincennes Barracks in a case of fracture of the skull which was not recognised, and was thought to be only a slight injury until the man became rapidly worse and died. Such mistakes must, unfortunately, from time to time occur, although happily they are rare. The rarity of such accidents of diagnosis in London reflects the greatest credit on the care of the hospital house surgeons. It is practically impossible for the public to realise the many difficulties which often lie in the way in these cases. There is, perhaps, no external injury to act as a guide, and too often the patient is in a condition of complete stupor from drink when brought into the hospital; usually he has been found unconscious, and no reliable history of any injury can be obtained. It is, indeed, scarcely to be wondered at if mistakes should sometimes occur under these conditions, although great care may have been taken to avoid them; and more especially so when it is remembered what a very large number of patients are every day brought to our hospitals unconscious from the effects of alcohol alone, and an examination of each one of these has to be carefully made with a view to finding other possible injuries. In all cases in which there is any room for doubt the only safe course for the house surgeon is to detain the patient until the alcoholic intoxication has to some extent passed off, when other symptoms may be recognised.

ANTI-VIVISECTIONISTS AND HOSPITALS.

THE anti-vivisection party are again endeavouring to win the general public over to their side by means of misrepresentations and omissions in the various accounts which they give of experiments. Canon Wilberforce and Mr. Ernest Bell both wrote to the *Times* on Nov. 30th and tried to show that hospitals are the homes of many horrors. Canon Wilberforce gives a list of many cases which have appeared from time to time, and as usual sadly misrepresents them. One quotation is: "Poor woman admitted to a hospital in a dying condition made the subject of constant observation and examination with tuning-forks, &c. These examinations were continued till her death, which occurred twenty-four hours after admission.—*Brit. Med. Jour.*, Oct. 27th, 1883." Now on looking this case up we find that a woman was admitted complaining of difficulty of speech and paralysis, the symptoms of which had lasted three months. A list of her prominent symptoms is then given, such as loss of power on one side of the face, deviation of the tongue, and so on, and then it is remarked that "a watch was heard one inch and a half from the right ear and eight inches from the left, and a tuning fork was heard best on the left side." Let it be observed how differently this is represented by Canon Wilberforce. The torture with tuning forks fades away into the simple act of putting the fork into vibration and asking the woman when she hears it. The woman died from cerebral tumour, and the case was simply examined in such a way that would lead to some hope of a diagnosis being made. One more example of these disgraceful quotations: "Experiment of injecting milk into the veins of a dying patient." This sounds by itself horrible enough, but a full account of the circumstances puts a very different complexion on the case. The author begins by saying that he believes injection of milk is of great value as a substitute for the transfusion of blood, as he had found that in many cases patients' lives had been prolonged by the operation. He then goes on to say: "I have perused most of the literature on the subject and find that many of the operations have been followed by marked success, in some cases by temporary and in others by permanent benefit, but sometimes no good has occurred from the injection (when improperly performed or when performed in unsuitable cases), and the operation appears to have proved fatal in a few instances." Cases: 1. Profuse uterine hæmorrhage; pulse 150; temperature 101°. All signs of impending death; eight and a half ounces of milk injected into median basilic vein. Pulse and temperature fell next day, and patient made good recovery. 2. Two cholera patients moribund. Injection of milk followed by recovery. Several other cases are given of which some recovered and others did not, but let the truth be noted as compared with Canon Wilberforce's misleading extract. Instead of "experimenting" on the patients, the injection is used as a substitute for transfusion of blood and gives the patient a last chance of living, and from the full reports of these cases there is every reason to believe that several lives were actually saved by the operation. No one can object to the anti-vivisectionists quoting whatever cases they choose in support of their doubtless well meaning but mischievous opinions, but those quotations must be made fairly and with due regard to their context. As representatives of an honourable and humane profession we cannot permit an undeserved slur to be cast upon its members, and the merciful work of hospitals to be impaired by enthusiasts who are unable to support their wholesale allegations.

ANTHRAX GERMS AND OATS.

A CASE has been recently tried before the Lord Chief Justice and a special jury in the Queen's Bench Division, which places the position of disease germs in a new and rather serious light. A firm of corn-merchants sued a lighterman and contractor to recover the price of certain Turkish oats. The defendant denied liability on the ground that the oats contained the germs of anthrax, which had caused the disease to break out in his stables, with the result that he lost fifteen horses, some of which were insured, but he counterclaimed in respect to the others. The plaintiffs, however, denied that the oats contained the germs of anthrax, and in proof of this they brought forward evidence to show that they had bought and sold a large quantity of these oats and had received no complaint except the one in question. The oats were said to have been very dirty and should have been cleaned before being given to horses in order that they should not render the animals liable to contract disease. A veterinary professor, who had witnessed extensive outbreaks of anthrax in England, stated he had known contamination to be produced by germs in a cart, and that germs spread very easily by being blown about as impalpable dust. Ultimately the jury found that the goods were unmerchantable by reason of latent anthrax germs, and that the defendant was not negligent in not having cleaned them, though guilty of negligence in regard to not having taken an order for a second supply of these oats off the file. Judgment was entered for the defendant for £280, the value of eleven horses which died in consequence of the first delivery of oats; the value of four horses that perished after the second delivery of oats was agreed to at £100, which amount was finally divided between the parties. The interesting

Digitized by Google

feature in this case is that no evidence was forthcoming to demonstrate that the oats incriminated were infested with anthrax germs, and their presence in this food was therefore a mere supposition, due to horses having succumbed to the disease after feeding on them, while the same kind of oats had been supplied to feed other horses, but no such fatal consequence had followed. Surely it was possible to give decisive proof of the actual presence of anthrax bacilli in the dust of the grain, and knowing that anthrax infection may occur through drinking contaminated water or consuming hay or grass containing these organisms, and in other ways, it does seem strange that the supposition was accepted as if it had been based on actual demonstration. The decision, at any rate if it is to form a precedent, will have far-reaching consequences when applied to the provision of suspected food to man and animals.

TYPHOID FEVER AT LUTON.

SOME weeks ago we drew attention to the epidemic of typhoid fever which was existing at Luton, and suggested that a full and independent inquiry into the sanitary condition of the town would be the best means of checking this epidemic and of preventing another in the future. This suggestion was also made by medical men in the neighbourhood, but the authorities have taken no steps towards such inquiry, and the result is that the fever still persists, and seems likely to do so until some more radical measures are taken to find out the source of infection. The cases have mostly occurred in one quarter of the town, and no doubt there will be found various defects to account for it. Among the deaths we regret to have to record that of a nurse named Allan, who died on Nov. 30th, having contracted the disease in the discharge of her duties. According to the Luton papers the inhabitants of the town are now taking the matter up, and will no doubt insist on a proper inspection being made. Typhoid fever is, to a very great extent, a preventable disease, and any failure to take full and adequate measures in dealing with outbreaks entails very grave responsibility on the authorities.

DISCOVERY OF UNKNOWN TRIBES IN AFRICA.

DR. DONALDSON SMITH, who has lately returned to England after exploring in Africa, has discovered no fewer than fifteen tribes. On hearing this news the question may be asked, What good end is reached by these discoveries? Are the people discovered the gainers—or might it not be better for them to be left in their primitive ignorance? With the benefits of civilisation will, doubtless, be also imported many of its vices. Probably the solution of the problem lies in the mean, and the evil and the good are fairly evenly balanced. Amongst the newly discovered people was a tribe of dwarfs, none of them exceeding 5 ft. in height. In the accounts published as yet the exact nature of the country is not stated, nor are the physical characteristics of the dwarfs described; it is therefore idle to speculate as to how near these pigmies are akin to the forest dwarfs found by Stanley, who are mentioned as having large heads and long beards. If, as is not unlikely, it was thick forest where Dr. Donaldson Smith met them there would be a strong presumption that they might be of the same origin, and to carry the speculation further it may be that in many parts of Africa amongst the dense unexplored forests there live tribes of dwarfs of like race, with like customs and habits. In fact, already there have been found by different travellers in Africa more than one tribe of dwarfs, notably the Batwas, 4 ft. 3 in. in height, and the M'Kabbas, near Lake Ngami, reported as averaging but 4 ft. It will be instructive to hear from Dr. Donaldson Smith a fuller description of the appearance of these diminutive men. How far the origin of the race of dwarfs has been affected by climatic influence is more or less an open question. Probably the comparative absence of light and air accounts for the forest men, as also for the Laplanders; but, on the other hand, this argument will not apply to the Andaman islanders or to the bushmen of Australia. When Dr. Donaldson Smith delivers his address before the Royal Geographical Society he will doubtless enter more fully into details, both with regard to the nature of the country and the appearance and habits of the people.

THE MURDER-MONGER.

AT Warwick Assizes, upon Dec. 10th, Sarah Ann Eden, a midwife, was condemned to death for the murder of a woman at Aston, upon whom she procured abortion and who died in consequence. This was no case of an unmarried ignorant girl in her first pregnancy trying to conceal her shame. For such criminals, wrong as they are, we may have pity, but in the present instance the woman was married and had six children. She first tried, with that indifference to this form of crime which so many women exhibit, to get her medical attendant to perform the operation, and when he refused she went to the prisoner. The crime of procuring abortion is far too common, and it cannot be too strongly impressed upon women that she who knowingly gets rid of her unborn child in this way is morally as much a murderess as the operator, and sins of this nature are not confined to the lower orders, but are only too frequent in the upper strata of society.

TRAUMATIC EPILEPSY AND OPERATION.

IN a recent number of the *Philadelphia Medical News* Dr. John D. Davis relates three cases of unusual interest and importance. The first is that of a man aged thirty, a farmer by occupation and without any history in his family of epilepsy, insanity, or other neuroses, who ten years before he came under observation fell a distance of fifteen feet, striking the back of his head on a piece of wood. Within an hour he was attacked by a severe convulsion, which lasted several minutes. After that he had on an average two convulsions a day, he was seldom free from headache, and had almost constant tinnitus aurium on the left side. He had suffered both in spirits and in appearance, and all the usual remedies had been unsuccessfully tried. The seat of the original injury was over the left occipital region, and it was proposed to trephine in this region in the hope that relief might be obtained. Accordingly operation was undertaken, but the membranes appeared healthy and there was no indication of a cyst or other morbid condition of the brain; but on the inner surface of the skull, about three-eighths of an inch from the trephine opening towards the parietal eminence, it was found that the bone was of almost cheesy consistence All this diseased material was removed and the wound dressed with the most rigorous antiseptic precautions. Convalescence was rapid and the result of the operation most gratifying. There was relief of headache, the tinnitus ceased, and at the time the paper was written, two and a half years after the operation, there had been no return of the convulsions. The second case related is that of a man who at the opening of the World's Fair in October, 1892, received a blow with a chair on the right parietal bone. He was unconscious for several hours and soon began to suffer from severe headaches. He became mentally deranged, suffered from epileptiform convulsions, and lost the use of the left arm and leg. When seen by Dr. Davis about a year after the accident he was suffering from intense paroxysmal headache, frequent convulsions, left hemiplegia, and mental derangement. No good effect being

Digitized by Google

obtained from drugs, trephining was performed over the right parietal bone. The dura mater bulged distinctly, and when it was incised about a couple of drachms of thin pus escaped. The cavity was washed out, and after the operation the patient's condition was materially better. There was, however, a return of symptoms ten days later, but these were relieved by dressing the wound, allowing some accumulated pus to escape. Since then there had been no return of the pain or other symptoms, and the left-sided weakness was much less and was still diminishing. The third case was that of a girl aged twenty-two who had had a fall on the back of her head while skating about sixteen months before she was seen. She was unconscious for several hours after the accident. Headache then became incessant and was increased by pressure on the back of the head. Her mental condition became very unsatisfactory, her appetite failed, she lost flesh, and suffered from about two convulsions a day. Operation was performed, and although there was every indication of very greatly increased intracranial pressure no actual lesion was found. However, three days after the operation the patient ceased to suffer from headache, the mental disturbance disappeared, and she began to gain weight. Eight months after the operation she had remained free from fits. These three cases are certainly remarkable, not only for the success with which they have been treated, but because of the interest which attaches to the different conditions found to be present—in one a softening of the skull at one point, in another an abscess, and in the third increased intra-cranial pressure without obvious cause. Dr. Davis is to be congratulated on the result of his operative treatment.

CAMARAN: THE CAUSE OF CHOLERA TO MECCA PILGRIMS.

COMPLAINTS are gradually accumulating as to the danger of retaining the Island of Camaran as a quarantine station in the Red Sea. It was shown by Dr. Thorne Thorne during the sittings of the International Sanitary Conference of Paris last year that the detention of intending pilgrims from India on that island preliminary to their being allowed to commence the land journey to Mecca had again and again been followed by an occurrence of cholera amongst them, although no suspicion of such disease had prevailed during the long sea voyage from Bombay to the Red Sea; and the verdict of a French physician was quoted to the delegates to the effect that Camaran was an *entrepôt cholérique*. Recent experience goes to emphasise and confirm this view, and reports have shown how utterly unwholesome, and even filthy, are the conditions to which the pilgrims are exposed during their enforced detention on the island. It is quite true that both at Paris and elsewhere promises have been made on behalf of the Sultan as to prodigious sums which His Majesty was just going to have spent on removing all sources of complaint; but promises of this sort now only cause an incredulous smile, and in the meantime it is known that during the last pilgrimage Camaran remained the *entrepôt cholérique* it has always been; soil, air, and water being liable to excremental pollutions of the worst sort. The past history of cholera, in connexion with the Mecca pilgrimage comes aptly to illustrate the mischievous results which this disease-producing quarantine station has led to. Between 1817 and 1866 there was an absence of quarantine detentions on pilgrims landing on the Arabian shore, and during that period cholera only broke out during the Mecca pilgrimage on two occasions—namely, 1835 and 1865. Between 1866 and 1881 a period of observation lasting twenty-four hours was imposed on arrival in the port of Jeddah, and again cholera only appeared during the Mecca pilgrimage on two occasions—namely, in 1872 and 1877. But since 1881, when the quarantine station and lazaret of Camaran were opened, and since which date Indian pilgrims have been compulsorily detained there for a period of five to ten days, cholera has actually broken out during the Mecca pilgrimage on eight separate occasions—namely, in 1881, 1882, 1883, 1890, 1891, 1892, 1893, and 1895. Well may our Mahommedan fellow subjects in India begin to demand the abolition of the compulsory detention of hitherto healthy pilgrims at this *entrepôt cholérique*. That demand is now being raised by those who are primarily concerned; but, under present circumstances, we fear that some money consideration which shall in some form or other make up for the so-called sanitary dues now imposed on the pilgrims will have to be offered before any such result is likely to be attained. In the meantime the Turkish possession of Camaran remains the greatest hindrance to the abolition of cholera in connexion with the Mecca pilgrimage.

INFANTILE MORTALITY AT CARDIFF.

AT the last meeting of the Cardiff Sanitary Committee the medical officer of health (Dr. Walford) was present, and by request read his report upon the alleged excessive infantile mortality at Cardiff. He stated that out of a total number of 608 deaths during the three months of the third quarter of this year 308 were of children under one year of age. Eighty of these were from diarrhœa. The deaths took place principally amongst children who were artificially fed. A discussion on the same subject took place at the meeting of the Cardiff Burial Board, when a medical man who is a member of this board and also of the Sanitary Committee stated that this excessive mortality was due to three causes: first, the deplorable lack of knowledge that prevails in all classes concerning the feeding of infants; secondly, the insanitary conditions in overcrowded districts; and, lastly, infant insurance, with regard to which he was of opinion that the Legislature ought to act.

THE HABITS OF BATS.

A VERY interesting paper on the habits of these curious animals in captivity appears in the current number of *Nature Notes* from the pen of the artist Mr. J. D. Batten, who has for years kept a number of them as pets. They appear to be easily fed on meal-worms, and to be extremely docile and easily managed, although none of them live for more than a few months in captivity. The account both of the waking from natural sleep and of hibernation is of great interest. Speaking of sleep Mr. Batten says: "The bat when thoroughly asleep is dead cold to the touch. If I then took it in my hand ..... it would lie quite still. On putting it to my ear I could hear a throbbing begin, at first very slowly and not very regularly, more than a second between the beats. Gradually the throbbing became quicker and quicker until it was impossible to count the beats; at the same time the warmth of the body was increasing rapidly and the bat quivering visibly. At last the throbbing becomes a continuous whir ..... and the body feels hot to the hand. Then rather suddenly the throbbing quiets down ....., slows somewhat, and becomes almost inaudible. The bat coughs or sneezes, chatters a little with its teeth, and moves about expecting to be fed." The noises heard must be to a large extent from the voluntary muscles. Some interesting observations are given as to the hibernation of bats and their behaviour when roused during that process. In the case of two bats that died during hibernation the spleen was found by Dr. F. E. Batten to be very large, while in one that died just before that stage and in two which died at other times of the year it was quite small. Much information is wanted as to the size of the various organs and the chemical constitution of

Digitized by Google

the tissues in hibernating animals. It is alleged that large quantities of glycogen are stored up even in the connective tissues—in such quantity that the masses of glycogen can be seen in the cells under a moderate magnifying power after staining with a weak solution of iodine. Practitioners living in parts of the country where hibernating animals, such as dormice and hedgehogs, are abundant have the opportunity of making original observations which would be of the greatest value in throwing light on very obscure physiological processes.

MEDICAL WITNESSES' FEES.

AT the Westminster Police-court on Dec. 10th Mr. J. E. Coulson, assistant medical officer of St. George's Workhouse Infirmary, gave evidence in a pauper case and applied to the magistrate for a certificate for his fee. Mr. Sheil refused, saying the petitioner had been sent by the workhouse and must ask the workhouse people for his fee. We do not believe that the "workhouse people" have any legal right to "send" their medical officers as witnesses, and next time such a case arises we should advise Mr. Coulson to refuse to attend without a subpœna and his fee.

RUBBISH.

WE had occasion, in our issue of Nov. 23rd, under the heading "The Friend of Humanity—New Version," to comment upon a letter sent out to publishers signed by Mr. Edward Curtice as managing director of the Newspaper Exchange and Advertisement Clearing House. The letter consisted, it may be remembered, of a proposal to supply the press with a popular medical article every week from the pen of "'Dr.' Allinson, the well-known Hygienic Physician," if certain advertisements of Mr. Allinson's books could be inserted in the columns of the various papers applied to. We have since received from a fellow-editor the following document, which would appear to be a circular letter to the provincial press from a "London correspondent." We have omitted certain reviews and notes on the trial of Jabez Balfour and the *Spectator* dog stories, but otherwise we print the communication exactly as it purports to have left the offices of Messrs. Romeike and Curtice:—

THE JOURNAL OF UNIVERSAL INFORMATION AND ORGAN OF THE LONDON NEWSPAPER EXCHANGE AND CLEARING HOUSE COMPANY.

No. 75. *Saturday, December 7th, 1895.*

I am sorry that my health prevented me publishing the Journal last week, and also that the weather stopped me calling on several big advertising agents to ask payment of long outstanding a/cs due to distant subscribers. I sent a clerk to a well-known advertising agent and he was most indignant and refused to speak to anyone except the principal, who lives 400 miles away, but why should any honest man delay payment, surely he could send a cheque direct. I will call on him myself on Monday.

* * * * * * * * *

I am sorry that some of my friends have taken offence because I sent out Dr. Allinson's advertisement. It should be understood that it is purely a matter of business, and I am paid to send it out. The anonymous scribbler who wishes me every evil wish and will give me a kicking when he meets me, is only wasting his time and stamps.

A few weeks ago I wrote that I had become a patient of Dr. Allinson's, and I am pleased to say that by diet only, and without physic, I am much better for his advice.

I was entrusted with the advertising for the Patti concert, and I think the order was carried out to the satisfaction of those who employed me as they sent a cheque and two stall tickets for the Albert Hall. My wife and I went, and regretted that the many millions in London cannot hear this wonderfully gifted lady. Her encore "Comin' thro' the Rye" was sung with all the witchery and coquetishness of a girl of 16, yet it must be 30 years ago since I heard her for the first time at Covent Garden at a benefit concert of Mr. Harris, the father of Augustus Drurylanius.

* * * * * * * * *

I have accidentally met with a booklet recently published by Messrs. Churchill, from which I think cancer-sufferers should derive much information of a decidedly encouraging nature. It is called "The Conditions of Radical Cure in Cancer." The author, Dr. Herbert Snow, a well-known Specialist on tumours and cancer, discusses the treatment of the latter which he regards as eminently curable by certain novel scientific methods and principles if taken in time. He considers opium, of old termed the "Divi donum," or special gift of God, as by far the best remedy for this fearful scourge we at present possess; and while confessing that it is not an absolute cure goes on to affirm: "Opium is the only drug which markedly checks the growth of carcinomata, and its early employment even when no surgical operation takes place will commonly add years of comfortable life."

Printed and Published by Romeike and Curtice, 359, Strand, London, W.C.

We do not think that the firm of Messrs. Romeike and Curtice will add much to any prestige they may rightly enjoy among those concerned in journalistic work and newspaper production by assisting in the dissemination of rubbish of this class, and we are certain that Dr. Herbert Snow will be grieved to find his name offered prominence in such a place.

THE PHYSIOLOGICAL ACTIVE PRINCIPLE OF THE THYROID GLAND.

DR. SIGMUND FRÄNKEL has made some valuable experiments in the Institute of Medical Chemistry of Vienna on the active principle of the thyroid gland. The results of feeding with animal extracts of the thyroid gland, adrenals, &c., in certain diseases have been most successful clinically, although the exact composition of the remedies has not been thoroughly understood. Several previous attempts have been made to discover the active principle of the thyroid gland, but hitherto without success. Dr. Fränkel experimented with known quantities of cold and warm extracts of the thyroid glands of sheep. The albuminous bodies were precipitated by acetic acid, and by feeding experiments he ascertained that the precipitate had no marked effect, whilst the filtrate that was obtained possessed the well-known properties of the thyroid gland, or, in other words, contained the physiological active principle. The filtrate was then chemically examined. It was first evaporated to a syrup, and on cooling solidified, showing the presence of gelatine derived from the connective tissue of the thyroid gland. By other experiments this gelatine was shown to be inactive. Fresh material was then taken and the albuminous substances and the gelatine precipitated by neutral acetate of lead, and the metal separated by filtration after precipitation by sulphuretted hydrogen. The residue obtained from the filtrate after evaporation was dissolved in alcohol and ether added, when a body was obtained which had the following peculiarities: it was intensely hygroscopic, and was soluble in water and alcohol. The watery solution had a neutral or slightly alkaline reaction, and only applying the usual tests for an alkaloid a positive result was obtained. Dr. Fränkel calculated the empirical formula as $C_6H_{11}N_3O_5$. He has provisionally named the substance "thyreo-antitoxin," as stated last week by our Vienna Correspondent. Investigations are being made clinically with this body, but sufficient time has not elapsed to establish any definite results. In experimenting on animals Dr. Fränkel failed to find the fall of blood-pressure demonstrated by Schäffer upon intravenous injection of thyroid extract, but acceleration of the pulse-rate was well marked. He also found that the hearts of frogs poisoned by muscarin, which had ceased to beat, could again be brought to act by dropping on them a few drops of a watery solution of the thyreo-antitoxin. In animals, too, after the thyroid glands had been extirpated and convulsions and other symptoms had followed, temporary recovery followed subcutaneous injections of a 1 per cent. watery solution of the remedy. These experiments agree with those made by Gley of Paris with injections of thyroid juice. Dr. Fränkel maintains, therefore, that he has demonstrated the isolation of the active principles of the thyroid gland, and that it is a pure chemical body, with well-defined chemical properties and occurring in considerable quantity in the gland. He anticipates that we shall eventually be able to administer this particular antitoxin in exact doses. As he has isolated it the body is odourless, and with a taste which "reminds one of the extract of beef rather than of the thyroid or its extracts." Another advantage he claims for the antitoxin is that we shall be able to assure ourselves of its purity, and

Digitized by Google

that it is free from ptomaines, for a case of poisoning has recently been reported through feeding with a thyroid preparation. It must be remembered also that many of these preparations offered for sale are rendered inactive through faulty methods of preparation.

THE LATE SURGEON-MAJOR PARKE.

A MEMORIAL brass has been set up in the parish church of Kilmore, Ireland, in memory of Surgeon-Major Parke, whose premature death evolved such widely expressed sympathy at the time, both in medical and lay circles. The following is a copy of the inscription: "In Memory of Thomas Heazle Parke, Surgeon-Major A.M.S.C., second son of Wm. Parke, Esq., J.P., of Cloghes House, Kilmore. Born Nov. 27th, 1857; died Sept. 11th, 1893. Beloved and honoured by all who knew him. He entered the Army Medical Staff in 1881; served in Egypt with distinction, accompanying the Bazuda Desert column of the Nile Expedition for the relief of General Gordon, 1884-85. From January, 1887, to December, 1889, he served on the expedition for the relief of Emin Pasha as surgeon. It is as a tribute to his constant gentleness and care for the sick and suffering, and to the splendid services he rendered alike to Europeans and Africans during the three years' march across Africa, that this tablet is erected in grateful and affectionate remembrance by the two surviving officers of the expedition, Henry Morton Stanley, A. J. Mounteney Jephson (lieutenant)." The brass is mounted on a slab of polished marble.

THE FRENCH ARMY MEDICAL SERVICE.

WE recently[1] alluded to the retrogressive spirit displayed by the military authorities in their treatment of the medical staff of the French army, and we regret to observe that the topic is still the subject of unfavourable comment in several of our Parisian contemporaries. The feeling of discontent amongst members of the medical corps is described as becoming daily more and more accentuated, and unquestionably, if the facts now adduced are exact, these neglected, not to say despitefully treated, officers have every reason to be dissatisfied. A writer in *La Revue Médicale*, signing himself Georges Collet, is responsible for the following serious allegations. When, in answer to a telegram from the War Office, General Duchesne despatched from Madagascar his list of nominees for admission to the Legion of Honour he *forgot* the officers of the *Corps de Santé*. The omission having been observed, the General-in-Chief's attention was invited thereto by cable, whereupon he at once sent home a second despatch giving the names of all the medical officers taking part in the expedition! It would, of course, be possible to interpret this extraordinary procedure in a complimentary sense; the General might be supposed to mean that where all had acquitted themselves so meritoriously it was impossible for him to make selections; but, unfortunately, no such flattering explanation can be accepted by people acquainted with the real state of affairs. It was notorious that when the Madagascar expedition was being organised very little attention was paid to the demands of the Medical Director; and throughout the operations administrative medical officers were compelled to engage with the superior staff of the force in never-ending contests whereof the echoes have traversed the seas. The truth is the *Corps de Santé* is on the eve of losing the position it has so laboriously acquired. The decree which overrode the law by removing all transport material from the control of the chief medical officer must be fresh in everyone's recollection. M. Collet's next charge is made on the authority of Dr. Noël, and refers to the remarkable manner in which the military medical element has disappeared during the last few decades from the officers' roll of the Legion of Honour. In order that the discrepancy may be seen at a glance we have constructed the following table from the materials supplied in our contemporary:—

Legion of Honour.	1868.			1895.		
	Total number.	Officers of the Legion.	Knights of the Legion.	Total number.	Officers of the Legion.	Knights of the Legion.
Médecins Principaux, 1st Class	40	36	4	40	30	10
,, ,, 2nd Class	40	26	14	45	11	34
Médecins Majors, 1st Class ...	260	59	200	313	10	253
,, ,, 2nd Class ...	268	—	98	330*	—	77

* Approximate number.

The position of *médecins majors* of the second class is declared by M. Collet to be deplorable. Before an officer of this grade can hope for promotion he must have from twenty to twenty-five years' service and be about forty-three years old. No medical officer can expect advancement in the Legion of Honour until he has served for at least thirty years, and even then he cannot count on it be his career ever so blameless. There are now several retired officers with more than this amount of service, inclusive of from ten to fourteen campaigns, who are not in possession of the coveted rosette. The department had great hopes when General Zurlinden was at the head of affairs that something would be done to improve its position; but he is no longer a Minister, and serious doubts are entertained regarding the friendliness of his successor, M. Godefroy Cavaignac. As we mentioned last week, M. Vigne stated in the French Chamber that the hygienic and medical arrangements in Madagascar were defective, but if the medical officers were treated as M. Collet says, it is not right that they should be made to bear any blame in connexion with the terrible mortality by which the expeditionary ranks were doubly decimated. A mortality of 20 per cent. in a few months should be a warning to all Governments and generals not to neglect medical advice when military operations have to be conducted in a bad climate, or, for the matter of that, in a good climate.

CASTS IN NON-ALBUMINOUS URINE.

A PAPER on this subject appears in the *Berliner Klinische Wochenschrift*, No. 14, 1895, by Dr. A. Kossler. The writer has made a study of the occurrence of casts in urine which does not contain serum-albumin, with special notice of their relation to nucleo-albumin. He accordingly investigated mainly cases of infectious fevers, tuberculosis, and various forms of poisoning, nucleo-albumin being more commonly found in connexion with such conditions than with nephritis. He examined the urine of twenty-nine patients which was free from albumin, and found casts of various forms in the majority of the specimens. Chronic pulmonary tuberculosis yielded the greatest number of positive results; in eighteen cases casts were found—hyaline and granular; and in a few of the cases epithelial casts also. Solitary specimens of blood casts of both varieties, red and white, and of amyloid casts were likewise reported. Two cases of rheumatic endocarditis gave similar results, and one case each of the following diseases—viz., scarlet fever, enteric fever, croupous pneumonia, empyema following pneumonia, and a prolonged case of severe bronchitis, in which the temperature remained high; there were also two cases of phosphorus poisoning and two of a febrile disorder of an uncertain

[1] THE LANCET, Sept. 28th, 1895.

Digitized by Google

nature. As before stated, all the specimens of urine examined did not contain serum-albumin, but the majority of them yielded nucleo-albumin in varying quantity, and the writer contrasts the occurrence of casts in connexion with nucleo-albumin with that of their occurrence with serum-albumin. Various circumstances go to show that the source of nucleo-albumin with casts is renal. Dr. Kossler had opportunities of examining twelve of the eighteen cases of pulmonary tuberculosis post mortem. In none of the cases were there any well-marked inflammatory changes, either diffuse or circumscribed, and he did not find in any of them cell-infiltration and exudation into the glomeruli. On the other hand, he was able to demonstrate changes in the epithelium of the urinary tubules: coarse granulation, well-marked cloudy swelling, and loss of nuclei, all stages of necrobiosis of the cells to the full destruction of the same. But these degenerative changes were not distributed through the whole of the kidney, but were distributed in small patches throughout the tubular structure. The occurrence, therefore, of casts with nucleo-albumin seems to stand quite apart from the ordinary exudative processes in the kidneys; the histological characteristics were entirely those of degenerative lesions of the glandular tissue.

AN ACTION FOR RECOVERY OF FEES BY A DENTIST.

AN important case was recently heard before Mr. Justice Mathew which opens up the question of fees. The action was brought by a dentist to recover fees to the amount of £105 for two small removable pieces of bridge-work, each carrying four teeth. The plaintiff, in support of his case, stated that the defendant had agreed to pay the sum sued for, but this fact hardly seemed to be supported by the subsequent evidence. Amongst other things we notice that the plaintiff stated he practised as a specialist in advanced American dentistry, and that removable bridge-work was never done by any dentist but himself. For the defence Mr. Charles Tomes gave evidence and expressed the opinion that the work was of a very ordinary character; was done by hundreds of dentists both here and in America; and that a fair fee would be about 30 guineas. The result of the case was that the plaintiff was allowed the sum of £30. In reviewing, this action we cannot help thinking that bridge-work is only too frequently used as a means of claiming large sums of money, and the patients, too nervous to face publicity, pay the sums demanded. The more quickly people begin to learn that there is no such thing as dentistry special to a country the less we shall hear of these cases. A few more decisions similar to the above would, we think, have a beneficial effect.

SYRINGOMYELIA IN A CHILD.

IN the *Revue Médicale de la Suisse Romande* Dr. Thomas relates the particulars of a case of this curious affection occurring in a child aged six. The patient went to a dispensary on account of severe and troublesome diarrhœa, but the hands were noticed to be peculiar in appearance. He was an only child, born at full term, but the labour was long and difficult. He had had digestive troubles and a severe burn in 1893. Two years before he was seen—i.e., at the age of four—the mother noticed that he did not seem to have pain when he was burnt. On examination the child was found to be of medium height and thin. There was a moderate degree of lateral curvature with the convexity directed to the left. The hands were large, stumpy, and cyanosed, and in the left hand the terminal phalanx of the index-finger had almost disappeared, while those in the other fingers and also in the thumb had been altered. Similar changes were present in the right hand. There was at least no marked degree of muscular atrophy in the hands and none in the legs, but while tactile sensibility seemed to be normal there was diminution of that for pain and for the appreciation of heat and cold. The knee-jerks were not obtained; there was no incontinence of urine, but loss of control over the sphincter ani. This case is peculiar and interesting because of the youth of the patient and the completeness of the clinical features of the case. An unusual feature certainly is the loss of control over the sphincter ani. But if, as seems likely to be the case in some instances, the condition which we designate "syringomyelia" depends upon a developmental defect in the spinal cord, such a defect of control might be due to a cause similar to, if not identical with, that which produces a similar weakness in certain cases of spina bifida occulta.

THE FORMS OF MUSCULAR ATROPHY.

IN his essay on the Duchenne-Aran type of progressive muscular atrophy (noticed on another page) Dr. J. B. Charcot does good service in presenting in tabular form the numerous conditions under which muscular atrophy arises, although, as he says, any classification in the present state of knowledge must be regarded as provisional. It may be useful to reproduce here the categories which he has formulated under the three heads of "myelopathy," "neuritis," and "myopathy."

MYELOPATHIC GROUP. — A. *Acute Amyotrophies.* 1. Infantile paralysis and adult spinal paralysis. 2. Acute central myelitis. 3. Hæmatomyelia. 4. General subacute anterior spinal paralysis. B. *Chronic Amyotrophies.* I. Protopathic Forms: 1. Progressive muscular atrophy, Duchenne-Aran type. 2. Labio-glossal laryngeal paralysis. II. Deuteropathic Forms: 1. Amyotrophic lateral sclerosis or muscular atrophy, Charcot type. 2. Hypertrophic cervical pachymeningitis. 3. Syringomyelia. 4. Tabes. 5. Various types of central myelitis. 6. Intraspinal tumour. 7. Disseminated sclerosis. III. Special form of family progressive muscular atrophy commencing in the feet and legs and involving the hands subsequently.

NEURITIC GROUP.—1. *Infectious Form: a.* Diphtheria, typhoid fever, &c. *b.* Primary infective neuritis, beri-beri. *c. Multiple* neuritis consecutive to syphilis and tuberculosis. 2. *Toxic Form.* 3. *Spontaneous Form*, neuritis *a frigore*, &c. 4. *Atrophic Form*, dyscrasic or cachectic, as from pernicious anæmia, chlorosis, cancer, diabetes. 5. *Sensory neuritis.*

MYOPATHIC GROUP.—1. Pseudo-hypertrophic paralysis. 2. Juvenile form of Erb. 3. Progressive muscular atrophy of infancy of Duchenne; facio-scapulo-humeral type of Landouzy-Dejérine. 4. Hereditary form of muscular atrophy of Leyden and Möbius. 5. Scapulo-humeral type of Zimmerlin. 6. Femoro-tibial type of Eichorst.

TREATMENT OF SMALL-POX BY EXCLUSION OF THE CHEMICAL RAYS OF DAYLIGHT.

IN September of last year Dr. J. Moir drew attention in our columns to this treatment of small-pox, and we have since received communications on the subject from Dr. Moir, Dr. Finsen, and Dr. Feilberg. Dr. Finsen has recently published an interesting historical account of the Red Light Treatment of Small-pox, the scientific basis on which it is founded, and the method of carrying it out. Dr. Feilberg states that he was at first very sceptical as to the influence of red light on small-pox patients, but, nevertheless, tried its effect on several unvaccinated children suffering from small-pox, and was surprised at the favourable course which the disease took. The vesicles did not suppurate, there was no secondary fever, and no permanent pitting resulted. The essential point for the success of this treatment, according to Dr. Feilberg, is that the patients should come under treatment during the early stages of the disease, shortly after the vesicles have appeared; if the seventh day has been reached suppuration can hardly be avoided. Another important point is that the exclusion of the chemical rays of daylight must be complete and continued until the vesicles have quite dried up. Dr. Moir, whilst admitting that Dr. Finsen bases his treatment on a scientific basis, and notwithstanding the extreme ability displayed both by him and Dr. Feilberg and the care and fairness shown by them in their papers, is still doubtful as to whether their explanations are correct. He admits that he criticises without experiment, but though he has not used

Digitized by Google

identical treatment yet he has given trial to somewhat similar experiments. For instance, he used to employ a solution of collodion and castor oil on the exposed parts to prevent suppuration and pitting, also, for similar reasons, iodine and glycerine solution, the latter particularly apparently meeting Dr. Finsen's chief requirements; but as the result of these and similar trials he still believes that the only distinction to be depended on as to the extent of suppuration and pitting is the presence and quality of the successful vaccination.

"HONOUR TO WHOM HONOUR IS DUE."

UNDER the rubric of "Palmam qui meruit ferat" a controversy has lately closed in the *Times* as to the real authorship of the saying, "He who never makes mistakes never makes anything." The ex-American Minister, Mr. Phelps, did indeed enunciate the aphorism, in a connexion, moreover, which drove its truth effectively home; and other publicists on the platform and in the press quoted it from him as a novel contribution to proverbial philosophy till prior claims were put in for its authorship, and it was assigned (*inter alios*) to the poet Goethe, the Emperor Napoleon, the dramatist Beaumarchais, and Mr. Samuel Smiles. The gist of the aphorism residing in the fact that "humanum est errare" and that the man who most is to be commended is he who errs least often, Napoleon was thought to have anticipated Mr. Phelps when he remarked, "the best general is he who makes fewest mistakes." But by none of the participants in the controversy was it shown that the aphorism is to be attributed to the Father of the Healing Art. In the Hippocratic treatise περὶ ἀρχαιῆς ἰητρικῆς (on ancient medicine) the author reserves emphatic approval for the physician who errs indeed, but who errs only in unimportant matters (τὸν σμικρὰ ἁμαρτάνοντα), and then follows the famous comparison of the practitioner to the pilot—a comparison, as was long ago pointed out by THE LANCET, appropriately addressed to an audience familiar with the difficult navigation of the Greek archipelago. Like all teachers of consummate ability Hippocrates possessed, and improved by practice, the art of condensing the results of observation or reflection in memorable phrases, and the aphorism in question is but one out of many in which he can be shown to have anticipated the wisest of the moderns.

HOSPITAL ABUSE AT BRIGHTON.

DR. WARING, whose communications to us on the above subject have made a wide impression, has returned again to the charge in a paper read before a special general meeting of the Brighton and Sussex Medico-Chirurgical Society on Nov. 26th. He adduced illustrations, for the accuracy of which he vouches, which are very striking. He learns from the reports of the various charities in Brighton that 38,113 tickets were distributed in 1894. If these did not represent 38,113 separate persons or cases, as is alleged, then the claim on the charitable is made on an exaggerated statement. He adduces striking individual instances of abuse in the cases of persons with good incomes, and of whom better things might be expected. He protests very properly against nearly a third of the women of Brighton being attended in their confinement by the midwives of the Lying-in Institution. One of the midwives of the institution has told him that over half the cases could afford to pay. We agree with him that as a rule all first cases should be denied charitable help. As an instance of abuse of a charity he mentions that of a gentleman, living in a large house and subscribing 10*s.* to a dispensary, sending a relative, who lives with him, to the dispensary for advice, and for one or two elastic stockings. It is difficult to tell where the charity comes in here, and the only conclusion we can come to is that the gentleman's conscience must be more elastic than the stockings which he gets for his friend at less than cost price. With equal force Dr. Waring protests against working men in the receipt of large wages dropping a penny weekly into the workman's boxes at railways and other works, and purchasing tickets for the sum so raised for the use in cases of common illness of all their relatives. This is not to help a charity, but to pauperise themselves and to cheat the medical profession. We can only notice another bad case. A patient suffered from cataract. Dr. Waring asked whether he could afford £5. He said he could well, and promised to let him hear soon, Dr. Waring meaning to get a surgeon in Brighton to perform the operation. Some time elapsed and he met the patient with apparently good sight. He had had the operation done "for nothing" at the eye hospital and by the very surgeon whom Dr. Waring intended to ask to operate for the fee which the patient could well afford. There is no morality or gratitude in such action of patients. And there is not much more on the part of the hospital that helps them. If such abuses in the name of charity are not corrected the institutions will die out. Their medical officers should save them by declining to be parties to so great an abuse.

HEALTH IN THE POST-OFFICE SERVICE.

THE Departmental Committee on Post Office matters held a meeting at the House of Lords on Friday last, Dec. 6th, Lord Tweedmouth presiding, when the important evidence of Mr. Arthur H. Wilson, chief medical officer to the General Post Office, as to the health of the employés was heard. From figures which Mr. Wilson gave in illustration we learn that the average number of days' absence from work in the year among the employés in the central office is 8·6, while the average staff numbers 6000 men. As the average number of days' absence from sickness in the country generally is a fraction over 9·0, it will be seen that this figure must be considered a satisfactory one, both from the point of view of the men and of their employer—the country. The average figure representing days of absence from sickness among the sorters was rather high; while in the senior telegraphist class it reached 12·3, a figure accounted for by the chronic illness of a few and not by any generally prevailing bad conditions. With regard to the death-rate in the Post Office the average age of the men in the service is about thirty-five years, and the death-rate is smaller than the general death-rate of the country, it being for the years 1891–94: postmen, 6·3; telegraphists, 4·2; and sorters, 4·1. The employés of the Post Office are known to consider that their average rate of sickness is high and compares unfavourably with the sick-rate of the working portion of the community between the ages of fifteen and sixty-five years. It would appear from Mr. Wilson's evidence that, at any rate during the four years with which he has dealt statistically in his evidence, the Post Office employés as a whole enjoy better health than men of about the same age engaged in many other occupations and professions.

THE WESTMINSTER PLAY.

IF the classics are worth teaching at all they are worth being taught well, and, to this end, the representation of Greek and Roman scenic masterpieces has, from the revival of letters downwards, been practised with satisfactory results, both at home and abroad, in the best organised schools. Westminster has long been distinguished among ourselves for the prominence she has given to such performances, and this year will continue the time-honoured tradition by the representation of the "Andria" of Terence. Exception, not altogether groundless, has, however, been

Digitized by Google

taken to the scantiness of the repertoire from which the plays are drawn. Three of Terence and one of Plautus recur with a frequency almost monotonous, until the scholarly outsider inquires if the school authorities are quite justified in so restricting their choice. Other plays besides the "Andria" or the "Phormio" or the "Adelphi" or the "Trinummus" are now read in good editions at not a few grammar schools, and would, if represented, be quite as effective on the stage as the best of the old favourites. Take, for instance, the "Menœchmi" of Plautus. This is an acknowledged masterpiece, and, besides, gives the reader or spectator a glimpse into the *vie intime* of antiquity not afforded by others of the same class. For one thing, it introduces the medical man as he posed and practised in the period of the Republic, before, that is to say, he was recognised by Julius Cæsar's famous edict as belonging to a liberal profession. Even then the practitioner had a house of his own specially adapted for the admission and treatment of cases, and in the "Menœchmi" he says—

"ego abibo domum
Ut parentur, quibus paratis opus est."

There the patient was under his direction and responsibility, and there also there was in attendance the *personnel* consisting of carriers and assistants at the disposal of practitioner and patient alike. The whole scene, with which the fifth act opens, is most interesting and instructive as an object-lesson in the private practice of Republican Rome, and suggests the further consideration of how far scenic representation might not be made subservient to reproducing for the modern world the characteristic life of the ancient.

"AN EPIDEMIC RELIEF SERVICE."

UNDER the above title we have received from a correspondent, engaged in nursing, a communication embodying some suggestions, in favour of which there is much to be said. She has evidently been impressed in practice with the enormous difficulty which is experienced in many country districts, owing to the lack of proper isolation accommodation, in dealing adequately with epidemics of infectious disease and by the no means infrequent supineness of rural sanitary authorities in the face of serious outbreaks, difficulties which, as she rightly observes, are enhanced in a high degree by the fatalism and ignorance of the poor. She refers to the utterly inadequate manner in which the directions of the medical attendant in matters relating to isolation and disinfection are carried out by the untrained persons into whose care the infectious sick in rural districts so frequently fall, and she is anxious, if possible, to see a better state of affairs brought about. With this praiseworthy end in view she suggests the formation of an "epidemic relief service" for use in outbreaks of infectious disease. Her proposal is that a roll of nurses skilled in the nursing of cases of infectious disease, and willing to be despatched to wherever their services are required, should be kept; a suggestion, in fact, much after the lines of that acted upon during the last cholera scare by the Royal British Nurses Association, and to which we drew attention in THE LANCET of Aug. 27th, 1892. There is little doubt, if the suggestions embodied in our correspondent's communication could be carried out in their entirety, that many lives and much suffering and inconvenience might be spared. It would be in times and places where epidemic regulations under Section 134 of the Public Health Act, 1875, were in force that the suggestions referred to would be of the greatest value; but this raises the question as to what is to become of the nurses enrolled during non-epidemic times. Obviously, if they were otherwise engaged they would not be available at a moment's notice without considerable inconvenience to their patients. The Isolation Hospitals Act, 1893, confers power upon a hospital committee to provide for the training of nurses in the nursing of cases of infectious disease, and this provision is that which approaches most nearly to the proposals made by our correspondent. The expense connected with the carrying out of her suggestions seems to be the chief objection to them; as to their value there can be no question.

OUR Russian Correspondent, as will be seen in another column, announces that the date fixed for the Twelfth International Medical Congress to be held at Moscow is the week beginning Aug. 19th and ending Aug 26th (these are the English dates), 1897. The president (acting) will most likely be Professor Klein, Dean of the Faculty of Medicine in the University of Moscow, and Professor Erisman, who holds the chair of Hygiene, has been elected general secretary. The official languages will be French and German.

THE trustees of the National Portrait Gallery have received from Mr. G. F. Watts, R.A., fifteen oil portraits and two drawings. The portraits are part of the series painted by Mr. Watts with a view of their eventually becoming the property of the nation, and among them medical men will be glad to hear is the face of Sir Andrew Clark in the good company of Matthew Arnold, Robert Browning, Thomas Carlyle, Cardinal Manning, John Stuart Mill, Dante G. Rossetti, the Earl of Shaftesbury, Lord Tennyson, and others.

PROFESSOR HAFFKINE, fresh from his practical work in connexion with the subject, will deliver a lecture on Preventive Inoculation against Cholera in India, on Wednesday, Dec. 18th, at 5 P.M., at the Examination Hall, Victoria Embankment. Members of the profession will, we understand, be welcome to attend.

DR. ARTHUR NEWSHOLME will read a paper on "A National System of Notification and Registration of Sickness" at a meeting of the Royal Statistical Society, to be held on Tuesday, Dec. 17th, at 5 P.M., at the Royal United Service Institution, Whitehall, S.W.

Pharmacology and Therapeutics.

PARACHLOROPHENOL IN LARYNGEAL PHTHISIS.

DR. SPENGLER in his dissertation (St. Petersburg, 1895) shows that parachlorophenol has considerable effect on tubercle bacilli in laryngeal phthisis when locally applied. After having observed its action by experiments on animals, twenty-six patients who were suffering from tuberculosis of the larynx and of other organs were treated, ten of whom appeared to be completely cured. The parachlorophenol was mixed with glycerin in various proportions, and when applied to the ulcerations on the mucous membrane of the larynx was found not only to cause no irritation but to have a soothing effect as well as a cicatrising action, the soothing effect being much more prolonged than that obtained by the use of cocaine. It was found applicable in all classes of cases and so is preferable to lactic acid and even to surgical manipulation. In cases of lupus of the mucous membrane, too, it acted very beneficially. Parachlorophenol was found, by experiment, to have a very energetic microbicidal action on tubercle bacilli, whether in pure cultures or as existing in the sputa of phthisical patients.

CHLORIDE OF AMMONIUM IN PHTHISIS.

Mr. A. Kebbell, M.R.C.S. (Flaxton, York), advocates the use of chloride of ammonium in even advanced cases of pulmonary phthisis. He generally gives it internally in doses of 7½ gr. taken in milk every three or four hours, and finds that it is followed by great increase of expectoration, improvement in sleep and appetite, and diminution of night sweats. He attributes its efficacy—which in his experience "surpasses any drug that I have used or seen used in the treatment of phthisis"—mainly to the

Digitized by Google

facility of expectoration and also, perhaps, to its action on the ulcerated surfaces. He hopes that others will give the drug a trial and report their results. Hitherto the use of chloride of ammonium has been mainly confined to simple catarrhal conditions of the respiratory tract, and its application in advanced tuberculous disease is, we think, novel.

VERATRUM VIRIDE IN ECLAMPSIA.

At the Society of the Alumni of Bellevue Hospital, New York, Dr. Barrows related two cases of considerable interest. The first was that of a young German primiparous woman who had been troubled with frequency of micturition for some time. About a week before her admission her legs had become swollen. The night before her admission on her way to visit her medical man she had fallen down, become unconscious, and had gone from one convulsion into another at intervals of about twenty minutes. The convulsions subsequently became more frequent, occurring every five minutes. On admission her temperature was 105·4° F., and the pulse 126, while her pupils were pin point in size. An ounce of urine was drawn off by the catheter, and this was found to be almost solid albumin and to contain granular and hyaline casts. The uterus was next emptied, the cervix being incised and forceps applied. Two hours after this the convulsions recurred. Two drops of croton oil were administered, and five minims of tincture of veratrum viride were given hypodermically every hour until four doses had been given. In a few hours her pulse became soft and regular, and her temperature was 100°. There was no recurrence of convulsions, and in twenty-four hours 108 ounces of urine were drawn off with a specific gravity of 1015. This contained a trace of albumin with hyaline and granular casts. Uninterrupted recovery took place. The second case was that of a multiparous woman seen on the same day. In her case a similar procedure was followed and with an equally gratifying result. Dr. Barrows, in a few remarks commenting on the cases, drew special attention to the administration of veratrum viride in such conditions. It had been for a long time used in the Southern States, apparently with success, in such cases as those described, and he directed special attention to its effect in promoting urinary secretion and in this way probably controlling the convulsions.

AN ITALIAN TOWN DAIRY.

BY W. W. BALDWIN, M.D.

I AM acquainted with an honest peasant family who have milk and sour wine to sell. They live wisely outside the city limits to escape that last and heaviest burden of taxation upon the poor, "il dazio consumo." This tax, of not under 25 per cent. is levied by our Florentine city government upon every necessity of life that passes any of the gates through the iron barrier drawn about Florence. A fine antique stone portal, with great wrought-iron gate of mediæval workmanship, opens into a picturesque paved courtyard. To the left rises a grey, grim, castellated tower, all that remains of a stately old Tuscan villa. In front of this stands a beautifully sculptured stone well-curb whose decorated iron top, doubtless wrought by the same cunning hand that created the artistic gate, over-arches all like a flower. To the right, encroaching somewhat upon the courtyard, lies a group of dilapidated houses in base stucco, doubtless of modern construction. These serve as tenements to various poor families, but the peasants live safely in the tower like hawks in their nest. The vineyard, with its trailing vines festooned from tree to tree, one of the peculiar charms of Tuscan landscape, leads down through ineffable vistas to a shining stream. The farther bank, covered with silver birches, aspens, and larches, rises abruptly to vine-clad slopes. Sweeping up beyond, like a vision, is one of the transcendent, indescribable panoramas of classic Italy, whose background is the noble-crowned height of Fiesole, uplifted above silver-grey olive groves.

My friend the peasant, for whom I had been waiting while making these observations, then came and conducted me to the cows, objects of my afternoon visit to this delectable nook of Old Florence. The stable upon inspection, with its thick stone wall, appeared to be the foundation for that group of flimsy houses to the right. There was a little wooden door by the side of a fine portal which had been bricked up and plastered over in true peasant fashion. Entering from radiant sunlight into dusky gloom, one could distinguish nothing until a barricaded window had been thrown open. Then a vaulted ceiling with supporting columns and exquisitely carved capitals, remains of frescoes long since irreparably ruined by damp and mould, and, above all, a beautifully proportioned interior, revealed what must once have been a gem of mediæval chapels. In a dark corner, standing knee-deep in stable litter, were two little dun-coloured cows, placidly blinking and eating of cabbage-stalks and other garden débris, truly a not very promising source of milk-supply, even with the help of the customary "elongation" from the well, it being a Tuscan superstition that "to baptise the milk encourages the cow."

"Do you turn your cows out every day in the field?" I asked. "Heaven forbid that I should tempt Providence," answered the peasant. "Some crazy English people once persuaded me to give my cows the freedom of the vineyard, because, they said, air and sunshine are good for milk. The blessed beasts went mad directly, and one, a perfect angel, broke her neck careering about. Truly," remarked he, with fine irony, "every wise man knows that cows require peace and quiet to ruminate prosperously, and the sun was ever bad for milk." Although the little beasts in question had been certified as perfectly well by a competent veterinary surgeon, nevertheless milk elaborated in such stunted, anæmic organisms from rubbish of food, in tainted air, away from sunlight, could not be wholesome. My friend and other peasants of reputed wisdom, moreover, assured me that rude change of immemorial habit invariably induces disease in these cows, which was proof, they thought, of great superiority in the Tuscan town dairy system. As unexceptionable milk, however, was my object, I did not seek to combat invincible prejudice at this time, but proposed, as a compromise, to purchase a "seasoned" Swiss cow upon my own account, the peasant contracting to feed her according to prescribed rule, to give a daily outing, and to strictly observe sanitary laws. A spacious octagonal temple (or antique summer-house?) in the vineyard happily afforded, with certain alterations, admirable stabling.

The problem of storing and transporting this milk unpolluted was most perplexing. One had dark suspicions that the well water was not free from organic infiltration, which subsequent analyses amply confirmed. The rush-covered flasks (*fiaschi*) of thin glass, universally employed to transport milk for immediate consumption, are picturesque, but very dirty, and swarming with bacteria. They are simply given a daily "lick and promise" with water from the nearest well, but never properly cleansed from one season's end to another. A kitchen near the ecclesiastical stable was then visited. Upon rude shelves in the corner were some green glazed terra-cotta receptacles into which the milking is poured and "baptised." An untrapped sink poured its tide of slop water, mixed with organic débris, into a leaky drain which could not be traced beyond the centre of the courtyard. "Here," said the peasant, "everything consumes itself." (These blind drains are popularly called "self-consumers.") In a dark alcove without means of ventilation except through the kitchen was a "luogo comodo" (convenient place), also untrapped. This opened directly into the large, unventilated, common cess-pit under the kitchen window, which was emptied every five or six months, and its contents employed for agricultural purposes. The smells from stable, sink, and cess-pit, together with something peculiar to generations of uncleanliness besides, made a combination too rank for any civilised nose. As might have been expected, this group of houses had been visited again and again by infection, various outbreaks of diphtheria having occurred, and latterly several children sleeping together in a room adjacent to the kitchen were down with scarlet fever. In the several Italian families supplied with this milk I discovered but one recent instance of undoubted infection from its use. A girl five years of age, who had not been exposed in any other way, sickened for a very mild attack of scarlet fever about fifteen days after first drinking it. From her the father contracted the disease and nearly lost his life in consequence. To this interesting case and the epidemic in general, however, I hope to devote a future paper. Here my purpose is to give a simple sketch of the average Italian town dairy. It is true one may not always find such a picturesque environment as at our farm even in Tuscany, but the trail of the mediæval serpent of uncleanliness is in them all. (One may except several

Digitized by Google

large dairies in the vicinity of Florence conducted upon the English system. These are unexceptionable in every respect, and at present supply the foreign colony with pure and wholesome milk.)

Perhaps the spell of antique Florence, slowly disappearing before the jerry-builder, possibly a missionary sentiment in cause of sanitation or personal friendship for the good, honest man, may have been my excuse for choosing this unpromising source of milk-supply. Be that as it may, our Swiss cow having taken possession of sanitary quarters in Diana's temple surrounded by vineyards, with food of the best and drinking-water from an unpolluted spring, our next step was to purchase an appropriate cart and English milking utensils of approved pattern, which are cleansed and sterilised daily. The cart, which stands when not *en route* under a thatched shed near our stable, serves meanwhile as dairy. Occasional unexpected visits are also made at the farm to ensure attention to detail. All this being satisfactorily accomplished, those mediæval horrors of leaky drains, foul kitchen, pestiferous stable, and unspeakable "conveniences" continually reproach one until steps shall have been taken to create there an oasis of sanitary righteousness. The question "Am I my brother's keeper?" will be easier to answer after these poor people have been delivered from the old haunting shadow of pestilence and death.

SANITARY EVOLUTION IN GLASGOW.

IT is not too often our good fortune to have to notice anything from the pen of the accomplished medical officer of health of Glasgow; but whenever Dr. J. B. Russell does appear in print we are prepared to find, not only that he has something important to communicate, but that his subject has been treated in a fashion at once able and refreshing. Unlike most other medical officers of health, on this side of the Tweed at any rate, Dr. Russell abstains from publishing an annual report, with rates of birth, sickness, and mortality, in orthodox form; and this he does from conviction that, except on the sure basis of a frequent census, even the best estimates of population for intercensal years must be so unreliable as to furnish rates which are merely worthless and misleading. In England, as in Scotland, this is well known to be the case, especially where small and rapidly changing areas have to be dealt with. Dr. Russell has, therefore, justification for the exceptional course to which he has for many years consistently and deliberately adhered. It by no means follows, however, that Dr. Russell fails to recognise the value of statistical methods, wherever these can be based on satisfactory foundations. That, on the contrary, he keenly appreciates the need of accurate numerical data as the very mainspring, as well as the test, of public health work, is proved by the excellent and comprehensive three-volume report on the vital statistics of Glasgow, which he issued after the census taking of 1881, the results of which formed the basis of the numerous and instructive tables which illustrate the volumes referred to.

We have just received another important contribution to sanitary literature from the pen of Dr. Russell, entitled "The Evolution of Public Health Administration in Glasgow," the subject being illustrated by the sanitary history of that city in the nineteenth century, with special reference to the period which has elapsed since the year 1854. From the preface we learn that an unbroken record of sanitary operations in Glasgow has been maintained throughout the last forty years. Speaking generally, the first ten of these years represent the period of awakening and groping for an instrument and a method; the remaining thirty represent the period of resolute endeavour, each successive decade exhibiting a stage in administrative progress. The anticipated revision in 1896 of the internal administration of the city, the removal and re-establishment in suitable premises of the sanitary department, and "the sense of quickening life now apparent in the city, which seems to foretell an era of new departures"—these are circumstances which, in Dr. Russell's judgment, mark the present time as especially opportune for a retrospect such as that which is now before us. In order to estimate the magnitude of the task which has been successfully grappled with in these last forty years it was necessary that some idea should be formed of the sanitary state of Glasgow in the first half of this century. Accordingly, Dr. Russell gives in Section I. of his book a review of the history of Glasgow from the commencement of the century down to 1854, Section II. being occupied with the results of public health work since the latter year and with the concomitant progress of hospital administration for the isolation of infectious disease.

Beginning with the opening years of the present century Dr. Russell gives a general survey of the several periods into which he has divided the ninety odd years which have since elapsed, keeping in prominence "a coherent reading of the moral of the narrative." In the years before 1855 the register of burials kept by the wardens of churchyards was the only available source of information as to the number of deaths or their causes. Mortality bills, made up from these sources and published from 1821 to 1832, kept vividly before the community the startling records of those times, when at frequent intervals the city was devastated by epidemics of fever and small-pox. Though typhus fever did not arrest attention specially until 1818, it had evidently been in the city from the beginning of the century. The subsequent history of this pestilence, in Glasgow as in other places, appears to have been like that of an active volcano, periods of deceptive repose alternating with violent eruptions. For short intervals infection smouldered in the "wynds," bursting out into epidemic fury as soon as the influx of immigrants had produced a susceptible population. Small-pox was scarcely ever absent, feeding chiefly on Celtic immigrants and becoming epidemic at intervals as they accumulated. There were three severe epidemics of cholera between 1832 and 1854, and in 1843 more than a quarter of the inhabitants in the poorer districts were attacked by famine fever. The present generation can with difficulty realise what such recurrent epidemics meant in the experience of their forefathers.

In 1837 the death-rate of Glasgow was 41 per 1000, one-fifth of which was caused by "fever" alone, which attacked at least 22,000 people in that one year. In 1847 the death-rate rose to 56 per 1000 living, of whom 10 per 1000 were killed by "fever," which is estimated to have attacked as many as 45,000 persons. It is proved beyond question, and the fact is attested by hosts of competent witnesses, that the sanitary state of Glasgow at the time referred to was at any rate as bad as neglect, prejudice, and ignorance could make it. Eminent medical men were then, as they have ever since been, to the fore in pointing out the dangers which threatened the health of the citizens and in suggesting appropriate remedies. At that period a large proportion of the population lived in dwellings so over-crowded on the soil as to be beyond the reach alike of sunshine and of air, and so confined as to leave no more space than was necessary for mere ingress and egress. The houses were constructed in utter defiance both of health and of decency, and their inmates were so completely deprived of the most primitive means of cleanliness as to have reached the lowest depths of physical as well as moral degradation.

We have not space for a tithe of the details by which Dr. Russsell so vividly pourtrays the wretched conditions existing in Glasgow at the period here referred to—conditions which would scarcely be believed to have been possible in the present century but for the unimpeachable character of the authority who vouches for the accuracy of the description. Still, notwithstanding the urgency of the protests which were addressed to the

Digitized by Google

authorities of the time, it was not until after the year 1854 that even the most elementary measures were initiated to redress the evils thus prominently brought to light. Under the immediate stimulus of the cholera epidemic of 1848 Glasgow had already acquired power to demolish ruinous and dangerous dwellings; but this power was practically a dead letter, and was only enforced in case of houses that could no longer hold themselves upright. As a matter of fact, but little permanent good was done even in these cases, for, in consequence of the want of by-laws, the greed of property owners rapidly covered again the old sites with buildings scarcely superior to those which had been displaced. As Dr. Russell aptly phrases it, "All this was mere scratching of the surface," and it was not until twenty years later that anything effectual was done to improve the condition of the homes of the people. Of sanitation, in the modern sense of the term, there was none. Medical writers of the time relate that the great cholera epidemic above referred to was in full swing before any attempt was made even to disinfect houses or clothing. The late Dr. Sutherland is quoted as testifying to the disgraceful inefficiency of what passed for the sanitary service, and as explaining that the reason why human filth was allowed to accumulate in the "wynds" and "closes" was because this material was the perquisite of the householders, and, therefore, was only removed when the farmers thought fit to fetch and pay for it. In the year 1859 was effected perhaps the greatest and most permanent sanitary improvement ever adopted in Glasgow. In that year the Clyde was discontinued as a source of water-supply, and a splendid service from Loch Katrine was obtained in its stead. Thenceforward a vast improvement was noticeable in the public health, and cholera, at any rate in its epidemic form, practically ceased to be. But it was not until 1862 that a Sanitary Committee was nominated, and not until the following year that the first medical officer of health received his commission. Subsequently a lay nuisance officer, with a small staff of helpers, was appointed to look after the typhus fever epidemic which at that time was raging in Glasgow. In 1870 the first sanitary inspector was appointed, with a subordinate staff of forty-two officers, five of whom were females, at that time a novelty. In 1876 the hospital treatment of epidemic disease was taken over from the infirmary authorities by the municipality, who, five years later, resolved to open their fever wards to all citizens free of charge. In 1883 a new public washing and disinfecting establishment was added to the municipal preventive machinery, the object being, on the removal of an infectious patient, to prevent the spread of disease by purifying the house and all the surroundings of the sick.

In our rapid and necessarily imperfect review of this interesting work we have now followed the history of Glasgow sanitation down to almost the present day. Before closing the book we would notice one omission which the modesty of its author does not permit him to supply. From beginning to end of the 140 pages not a word is mentioned of the part which the medical officer of health himself has taken in the splendid sanitary achievements of the last quarter of a century. The name of J. B. Russell is, however, a household word throughout the public health service, whose members will, we believe, with one accord acknowledge the obvious fact that it is mainly to the energy, ability, and self-sacrificing care of Dr. Russell himself that the vast improvements chronicled in these pages have been effected.

IN Dr. Seaton's summary of notification returns in the administrative county of Surrey we notice that the county was quite free from small-pox during November, Influenza was present in several districts, but apparently does not prevail to a notable extent except in the Frimley district.

PUBLIC HEALTH IN THE CITY OF CHICAGO IN 1894.

CHICAGO, with its population of 1,567,727, is at the present time the second largest city of North America, New York, possessed of a population of 1,957,452, being the only one exceeding it numerically. After Chicago come Philadelphia and Brooklyn with populations of 1,139,457 and 1,055,000 respectively. Some idea of the cosmopolitan character of the people of Chicago may be gathered from the fact that there are in it but 949,092 Americans out of a total population exceeding one and a half millions, and that several of its districts are so distictly foreign as to necessitate the employment of interpreters on the sanitary staff.

In his annual report for 1894 Dr. Arthur Reynolds, the commissioner of health, states that "Chicago continues to be not only the healthiest large city on the American continent, but the healthiest among all cities of magnitude in any quarter of the globe." He considers that the figures given at the official census were too low, but taking these as the basis of calculation the year 1894 yielded a death-rate of but 15·24 per 1000 of the population, and the "phenomenal healthfulness of the city continues to be a theme of incredulous comment by less favoured localities." In a table furnished in the report under review are given the population and death-rate of all the cities of the United States having populations over 200,000, and from this it appears that the rates in the several towns vary from 15·24 in Chicago to 24·88 in New Orleans. Taking now what are called the five lake cities—i.e., Chicago, Detroit, Milwaukee, Cleveland, and Buffalo, all of which are situated in the region of the great lakes and which together contain about 30 per cent. of the aggregate population of the great towns—it is found that their death-rate is but 15·56 per 1000, as compared with a rate of 19·88 per 1000 in the remaining cities. Dr. Reynolds states that an urban rate of less than 18 per 1000 has been pronounced incredible by the highest statistical authority in his country, and he wonders what will now be said as to the aggregate death-rate of the five lake cities. Dr. Reynolds will probably, too, wonder what the same authority will say to the 1894 death-rate of 17·8 per 1000 recorded for the 4,349,166 population of London. The death-rates of the five lake cities are certainly remarkably low, and it will be interesting to know to what their exceptional rates are due; whether, for instance, to any peculiarity of the age distribution of the population, or to the salubrity of their geographical position. The death-rate among the coloured element of Chicago—which amounted last census to 24,889—was during 1894 at the rate of 26·67 per 1000, as against a rate among the white population of 15·05. Violent deaths were responsible for a considerable portion of the mortality in Chicago during last year, and this seems to have been in large part due to the fact that within the corporate limits of Chicago there are over 2000 miles of railroad tracks, with more than 3000 street crossings over which 1400 trains pass daily. In spite of this the corporation does not compel the railway companies to maintain gates at the crossings, or even to employ signalmen to warn passengers of the approach of trains; in fact, one of the leading medical journals has spoken of Chicago as the "most blood-guilty city on earth." The epidemic of small-pox which occurred in Chicago during 1894 was, Dr. Reynolds reports, "the lesson of neglected vaccination," but nevertheless it is very interesting to observe the manner in which, when the consent of the city council had been obtained, vaccination was carried out. In one month no less than 586,500 vaccinations were performed, and in the whole year 1,084,500 out of a population of about 1,600,000. This work was performed by 500 vaccinators, specially appointed. Dr. Reynolds supplies a chart in his report showing the remarkable manner in which small-pox, although obviously in the ascendant, was at once arrested owing to the wholesale vaccination. Dr. E. Garrett, the chief medical inspector of Chicago, states that in his experience the vaccination of nursing infants is a difficult matter, and that they also manifest for a short time after birth resistance to small-pox. The diagnosis of the exanthemata in the case of negroes is said

Digitized by Google

by the same observer to be a very difficult matter, and for this reason all doubtful cases occurring among the coloured population are at once quarantined until the diagnosis is established. Dr. Benson and Dr. Chapman, two of the medical inspectors, in reporting upon the small-pox hospital, state that as a result of their experience they have arrived at the conclusion that there is no period of life at which vaccination may not be safely performed, and that there is no physiological condition in which the human animal can exist which will contra-indicate the performance of vaccination. It is to be regretted that the two gentlemen just referred to do not give more details in respect to this very interesting question. It may be added that Dr. Benson and Dr. Chapman make a practice of washing the arm to be vaccinated with soap and warm water, and, after washing, to rinse with "rather hot water." Dr. Warren, the physician in charge of the Chicago small-pox hospital, which building he considers a disgrace to "the metropolis of the West," records two cases of variola in domestic animals. In one case his own horse developed a typical variolous eruption which passed hrough the papular, vesicular, and pustular stages; and in the second case a cat brought into the hospital wards went through similar symptoms a fortnight after admission.

There are many other interesting subjects in Dr. Reynolds's elaborate report to which we wish we could devote space, but we must limit our further remarks to the water-supply of Chicago and its apparent effect upon the death-rate from enteric fever. Many of our readers have probably fresh in their memories the Report of THE LANCET Special Sanitary Commission of Inquiry concerning the Water-supply of Chicago, U.S.A., which appeared in THE LANCET of April 8th, 1893, so that it will be unnecessary to do more than state that since the date in question some of the intakes in Lake Michigan have been so lengthened as to ensure that all water supplied to Chicago shall be taken in at a distance of at least two miles from the shore. Dr. Reynolds contributes a special report upon the water-supply of the city at the end of 1894, and he states that the chemical and bacteriological analyses which have been made from time to time show that, in the "conservative" phrase of the laboratory director, Dr. Gehrmann, "the character of the water is that of a usable drinking-water." It seems, too, that, after storms followed by winds which tend to carry the shore water in the direction of the intakes, the number of bacteria in certain of the shorter intakes has been excessive, and there have, too, been indications chemically of an excess of organic matter. The water from the four-mile intake has been not merely usable, but a pure water as classified by analysts. There is obviously, Dr. Reynolds observes, need for more four-mile tunnels. Taking now the typhoid fever mortality of Chicago as an index of the purity of its water-supply, it is to be observed that between Jan. 1st, 1890, and Dec. 31st, 1892, at which latter date water was let into the four-mile tunnel, the annual death-rate from enteric fever averaged 11·5 per 10,000 of the population. In 1893, during the first year of using the new tunnel, the rate was 4·18, and in 1894 3·14 per 10,000. The reduction in the typhoid fever mortality was shown by all the wards in the city, and this fact is, Dr. Reynolds considers, in favour of the reduction being due to improved water-supply. A remarkable reduction has also been observed in diarrhœal mortality.

Up to the close of 1892 Chicago had the highest typhoid fever mortality of the several principal cities of the Union—all those having populations of 200,000 or over. In 1894 it ranked tenth amongst the seventeen. This reduction in the typhoid fever mortality is certainly a very striking one, and much of the evidence adduced tends to support a thesis of water-borne infection as an explanation of the prevalence and decline of this disease. Still we must confess we shall await with interest the rates of subsequent years. Other American cities besides Chicago have evinced within recent years some very remarkable fluctuations in their death-rates from typhoid fever. For instance, the city of Detroit in 1890 and 1891 ranked first in the list of large American cities as regards the smallness of its enteric fever mortality, while in the following year it occupied a place sixteenth in the list, rising again in 1894 to the fourth place. Dayton, too, has had its oscillations in this respect, as also has St. Louis. One of the most interesting papers in the Chicago report is by the Chief Smoke Inspector, and it will well repay perusal by those medical officers of health more especially concerned with the smoke nuisance.

A TURKISH ARMY SURGEON.

MR. WILLIAM V. HERBERT, the author of "The Defence of Plevna, by One who Took Part in It," has received a letter from Dr. Charles Ryan of Melbourne, who in 1877 was one of the surgeons in Osman Pasha's army. The following extracts may interest our readers:—

"I saw your book yesterday for the first time and read it with intense interest. I am an Australian by birth. I graduated in medicine from the University of Edinburgh; thence I went to Paris, where I spent a few months at the university; and finally spent the winter of 1875-76 in Vienna. I always had a strong desire to visit the East, and in taking up the *Times* one day I saw an advertisement to the effect that the Turkish Government required thirty surgeons to proceed to the seat of war (the Servian war had just broken out). I obtained an introduction to the Turkish ambassador, and received an appointment at the rate of £200 per year, to be paid in gold, the rank of a major and four rations. I proceeded to Constantinople, where I spent a week, and one fine morning early in June I found myself in the train with a thousand Turks, bound I knew not whither. We travelled together to Tatar Bazardjik, thence we marched to Sofia, where we spent a few days. From Sofia we went to a place five miles the other side of Pirot, where we camped, not very far from the Servian border; thence we marched to Akpalankah, where we spent three weeks, and thence to Nish. After the fall of Alexinatz I stayed in Widdin until Osman Pasha's departure to Plevna.

"I cannot imagine who the long English correspondent mentioned in your book could have been. The only English correspondents that I knew were poor Nicholas Leader, who died in the Shipka Pass a short time afterwards, and poor Frank Power, who was afterwards British Consul in Khartoum, and was killed by the Arabs with Colonel Stewart.

"On the declaration of peace with Servia, Osman Pasha gave a ball, to which none but field officers were invited. We sent to Crayova in Roumania (*fifty miles*) for our supper. I was curious to know where our partners were to come from, and was amazed to find so many pretty girls present, chiefly Grecian, Bulgarian, Roumanian, and Spanish Jewesses, and you know how pretty some of the latter were. Three days before war was declared I hired a boat and paid a visit to Calapat, and spent a most interesting day. I remember well the scene that occurred when the first shot was fired. I was lunching with Colonel Stracey, at a hotel kept by a Polish Jew on the banks of the river, when, without any warning, the guns began to fire. The excitement and the scene which followed are admirably portrayed in your book. This was at 1 P.M. on July 19th, 1877. I jumped on my horse and rode due north, tied up my horse on the left side of the range, and went up to where we had three batteries of artillery in action, and I saw one of the layers, while setting a gun, have his head taken clean off. I was so affected that I turned sick and vomited. A month later I could have seen fifty men have their heads taken off without feeling the slightest emotion. There were only seventeen surgeons in Plevna at this time, and we were working for about forty-eight hours on a stretch. It was our custom, as you are aware, after heavy engagements to dress the wounded and send two-thirds of them in carts to Sofia, leaving behind only the gravely wounded who were unable to travel. With regard to our medical staff, Hassib Bey was, as you state, our head—a very decent old fellow, who took a fancy to me. Most of the doctors were Hungarian Jews; there was one Austrian and one Hungarian called Kronberg. Kronberg was the only man in the whole crowd who had a spark of pluck, the rest were arrant cowards.

"During the second battle of Plevna I rode out continually from the headquarters camp. I was provided with bandages, lint, &c., and lent a helping hand wherever I saw any wounded. The Russians having commenced to flee Hassan Sabri Pasha gave the order for the cavalry to follow them up, and my friend Mustapha Bey waved his sword to me and shouted, 'Come along.' Eventually the order was given by Hassan to retreat, as he was afraid lest our retreat would be cut off, and we galloped towards a field of maize. Never will I forget my sensations. While facing the enemy I had no fear, but now all was changed. When you are in the open and the bullets come hissing past you, you cannot say how close they actually pass; but on this

Digitized by Google

ride I saw the bullets striking the leaves and stems all about me, and for many years afterwards, whenever I had nightmare, it was always that ride through the maize field. On the morning following the battle I rode out to the Grivitza redoubt and saw close by an immense number of Russians dead. They were all stripped naked, and many of them were in the most extraordinary postures.

I took part in the fight at Pelishat (Aug. 31st), our ambulance being placed about three-quarters of a mile behind the fighting. When the troops retired two soldiers, one dying with a wound through his neck and the other with a shattered thigh, were being left behind. The most adventuresome of the Russians were within 200 yards of me, but I carried these two wounded on my horse for about a mile, when the man with the shot through his neck died, and I was able to bring the other man back to Plevna. I also took part in the expedition to Lovdcha (Sept. 3rd). I received no warning, simply jumped on my horse, took my great-coat and a few instruments. When we got within about four miles of Lovdcha we were told that the Russians had taken the place two days previously. I accompanied the cavalry, and we came to a large knoll, on which were thirty or forty walnut trees, and there we met with a horrible spectacle. Some 400 Turkish soldiers in their flight had been overtaken here and killed. Each man had his rifle broken beside him; their faces were slashed, and they were cut to pieces. On the march back to Plevna we passed several deserted Bulgarian villages. Those memorable days in September, can one ever forget them? I had a little desultory fighting on my own account when Skobeleff was taking the two redoubts and the troops were flying in hundreds, and the shrapnel shells were exploding on the Plevna side of the hill. Riding to the redoubt I did my level best to rally the troops. During the night we moved all the wounded who were in the hospitals in the south of the town to the north, and the next morning we had something like 3000 of them lying out in the open near the main road. My house was so close to the Kavanlik redoubt that during the night my horse, which was tied up in the yard, received a bullet wound, and all night long the bullets kept striking the shutters. The dreadful uncertainty of that night is strongly impressed on my memory. The morning broke on a terrible scene. After Tewfik Pasha's glorious success I remember the joyous cry of 'Allah!' given vent to by our troops as they rushed forward. This was taken up by the reserves in the valley below, thence travelling like *feux de joie* all over the lines of Plevna. We were now in a state of siege, and our stock of bandages, medicines, dressings, &c., had run out. We had 5000 wounded to look after. I alone had charge of between 200 and 300 of the most gravely wounded, with only two Iarrabashi, or Turkish surgeons, to assist me. Nothing could have been more terrible than the position in which I was placed: absolutely without remedies or dressings, an hospital which contained five times its proper number of inmates, and nearly all the wounds maggoty. All I could do was to scoop out these creatures with my fingers. I had no beds and no mattresses; the men were lying on the floor in the clothes in which they were shot. More brave, enduring, long-suffering, heroic patients I shall never see again. I was so disheartened at the dreadful misery and my inability to alleviate it that I felt inclined to sit on the steps of my house and cry like a child. The only correspondent we had was Ollivier Pain, a French Communist. As he had no proper firman Osman Pasha sent him back to Constantinople to obtain one, and he returned to Plevna shortly after the third battle, before the taking of Telisch. He it was who wrote that most stirring and noble reply of Osman Pasha to the Grand Duke in which he declined to surrender Plevna. I remained in Plevna until the second week in October. During this time I was worked pretty well to death. The enormous number of wounded we had on hand, and the few medical men, will easily account for that. A few days before the Russians cut off Plevna for the last time by the taking of Garna Dubnik I went to Constantinople, and before I could get back to Plevna it was closed to the outside world. I then went straight to Erzerum, where I served through the siege. There were no correspondents there, and if the horrors of that siege were written people would not credit that such things could happen in this enlightened century. I have as the result of my daily intercourse and my insight into their character the highest admiration for the Turks. I have always thought that a Turkish army commanded by British or German officers would be well-nigh invincible.

"In conclusion, allow me to offer to you my sincere thanks for the intense pleasure your book has given me. It has awakened some of the pleasantest recollections and memories of my life."

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE CASE OF MR. R. B. ANDERSON.

A DEPUTATION from the Civil Rights Defence Committee, introduced by the Earl of Stamford as President, waited on the committee of the Association of Fellows of the Royal College of Surgeons of England on Wednesday, Dec. 4th, 1895. Mr. George Pollock, President of the Association, occupied the chair. The deputation consisted, in addition to Lord Stamford, of Major-General Graham, Mr. R. B. Anderson, Mr. Henry Anderson, and Mr. Walter Rivington. Telegrams and letters regretting inability to take part in the deputation were received from Mr. William Williams, J.P., treasurer of the British and West Indian Alliance, Mr. H. T. Butlin, treasurer of the British Medical Association, Dr. E. G. Younger of the London and Counties Medical Protection Association, and the Hon. Stewart Erskine, Vice-President of the British and West Indian Alliance. Before proceeding to the business of the deputation the hon. sec., Mr. Percy Dunn, read a letter from General Graham conveying the thanks of the Civil Rights Defence Committee to the committee of the Association for having, at the last meeting, adopted a resolution expressing appreciation of the action of the Council of the College in coöperating in support of the rights of a Fellow and Member. A letter was also read from Mr. Holmes to the effect that the published reports of Mr. Anderson's case made it quite clear that he had suffered the grossest injustice as well as indignity—the former at the hands of the Trinidad judges, and the latter at those of the English—and that he ought to be fully and fairly compensated, and that the Association could not be better occupied than in supporting Mr. Anderson in obtaining compensation and the reversal of the illegal sentences and orders against him.

Lord Stamford then briefly introduced the deputation, and called upon Major-General Graham to read a statement as to the measures now being adopted by the Civil Rights Defence Committee.

After thanking the committee of the Association, Major-General Graham expressed a hope that the measures adopted would be confirmed by the general meeting of the Association on the 11th inst., and that the example would be followed by every remaining medical or surgical association or society in the kingdom. In such a hope they had already had much encouragement, several branches of the British Medical Association having organised subscriptions, and some having voted amounts from their funds. The Torquay Medical Society had lately done the same, recommending a vote of £5 from its funds, and organising a uniform subscription of 5*s*. each from members, amounting in all to £18. Besides this, that society had adopted resolutions calling upon Her Majesty's Ministers, Members of Parliament, public men, and public bodies to unite with the Civil Rights Defence Committee in defence of the common rights of all medical men and all British subjects, and had obtained the signatures of its members to a memorial to Commander Philpotts, R.N., M.P. for the Torquay Division. Mr. Cohen, M.P., had come forward in the most generous way and promised his support to the committee. The Council of the British Medical Association had been asked to use its great influence with its branches throughout the country, and the friends of Mr. Anderson in Lincolnshire, his native county, were taking up the matter warmly. By such means it was hoped to enlist the sympathy and coöperation of other public bodies, especially the guilds and corporation of the City of London, than which no public bodies in the kingdom were more interested in standing forward, and being seen to stand forward, in defence of the ancient rights and liberties of Englishmen. They had a special ground to do so in this case, since the

Digitized by Google

rights of one of those guilds, the Worshipful Society of Apothecaries, had been violated, Mr. Anderson being a licentiate and also a silver medallist of that guild, and his licence granted by them under Charter being rendered valueless. Careful and patient methods were essential to success, and only general coöperation and voluntary aid such as had been described could win the contest of truth and justice and law against malice and unlawful oppression. Major-General Graham concluded by asking the Association to appoint a representative on the Civil Rights Defence Committee.

In response to an appeal from Lord Stamford Mr. Rivington supported the proposals of the deputation, and remarked that there had been nothing like the case of Mr. Anderson since the time of James II.

Mr. Gant, who had lately read the papers, stated that he had been filled with amazement and literally bewildered, the history of the case being more like some extraordinary fiction than bare facts ascertained and proved.

Dr. Robert Barnes remarked that it was stranger than any fiction.

In response to questions Mr. Anderson explained that he was not originally singled out for attack, but that the attack by Sir John Gorrie was against all the more respectable portion of the community in Trinidad and Tobago, and that it had been so powerful and overwhelming as to reduce its victims to complete helplessness and submission, so that he became eventually the sole individual able to maintain any resistance. Sir John Gorrie's motive was to figure as the champion of the black people and lower classes. Full particulars of the medical case were given in the first interim report, and in the letter of the three other medical men in Tobago (Dr. Tulloch, Mr. Purser, and Dr. Blance), as well as those of the two other cases amalgamated with it. Mr. Anderson further explained how the general principle involved in the wrongs done to him affected others equally.

Mr. Pollock, on behalf of the committee, undertook to bring Mr. Anderson's case before the Association at its general meeting.

The deputation then withdrew.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Staffordshire County Sanitary District.—The population of the administrative county of Stafford, estimated to the middle of 1894, was 797,101; its general death-rate for the year was 16·2 per 1000 (urban 16·5, rural 15·4), and the zymotic mortality 1·47 per 1000 (urban 1·68, rural 0·97). Dr. George Reid, as heretofore, adheres to his plan of reporting under subject headings, in the place of summarising separately the report of each medical officer of health in the county, a practice common amongst most other county medical officers of health. The sanitary committee of the county council has recently delegated some of its detailed work to three sub-committees, a step which appears to have had the effect of considerably facilitating their procedures. During the year 1894 numerous inspections of water-courses were carried out by the council in its capacity as a sanitary authority under the Rivers' Pollution Acts, and satisfactory progress has, Dr. Reid states, been made in the prevention of river pollution. In connexion with this subject it appears that an appeal on the part of the Staffordshire County Council to the Warwickshire County Council for assistance in obtaining information in regard to the pollution of the river Tame during its progress through Warwickshire did not meet with a very hearty response, and Dr. Reid has therefore been requested to ascertain the facts himself, and to report to the council as to what share the Warwickshire local authorities have in the pollution of the said river. In addition to the inspections of rivers in the county considerable attention has been paid to canals, and the pollutions discovered have been brought to the notice of the canal companies, who bid fair to become valuable allies as regards the prevention of pollution. In the matter of small-pox Dr. Reid regrets that with few exceptions the local reports do not contain such information as regards the incidence of the disease upon the vaccinated and unvaccinated as to enable a full summary to be given, but he supplies the following statement, which is of considerable interest. Of 1356 cases, 1183 occurred among vaccinated and 173 among unvaccinated persons. The deaths numbered 77, of which 23 occurred among vaccinated and 54 among unvaccinated persons, so that the case mortality in the two classes was as follows:

	Per cent.
General case mortality	5·6
Case mortality among vaccinated persons	1·9
" " unvaccinated persons	31·2

The medical officer of Handsworth, in reporting upon some cases of enteric fever which occurred in his district, states that in two cases the evidence pointed to the consumption of mussels as the cause. Unfortunately we are not told whether in the cases in point the mussels were consumed raw or cooked. Dr. Reid furnishes in his report an interesting table showing to what extent the isolation hospitals are made use of in the respective districts. There is, as was to be expected, an enormous difference in the several districts in the percentage of cases isolated as compared with those notified. For instance, in the urban districts where isolation accommodation is available the percentage of isolations to notifications varies from 1·3 per cent. to 90·3 per cent. The divergencies are accounted for in large part by the imperfect accommodation provided in some instances and by the charges for admission which are made in others. As bearing upon this question Dr. Reid hopes that a conference will shortly be held at which the provision of isolation accommodation for the county will be considered.

Bradford Urban Sanitary District.—So long a period has elapsed since we have had the pleasure of noticing one of Dr. Arnold Evans' reports that we were beginning to have doubts as to whether he had continued the practice of issuing annual reports. We have, however, just received those for the years 1893 and 1894 bound together. The most interesting part of the volume is the table relating to the incidence of small-pox in and around the Leeds-road Fever Hospital during the last epidemic of the disease in Bradford, and the history of Bradford's action as a result of the experience then obtained is instructive in a high degree. The broad facts in connexion with the occurrence are briefly these: an exceptional incidence of small-pox occurred around the Leeds-road Hospital shortly after acute cases of that disease were isolated there, an incidence which fell upon the houses in the several quarter-mile zones from the hospital outwards in the percentages of 10·4, 6·8, 2·1, and 1·0, the incidence on the houses in the whole of the borough being 1·6 per cent., on those in the special area 3·6 per cent., and on those outside the special area 0·6 per cent. These remarkable gradations in incidence were best explained, Dr. Evans stated, in a paper he read before the British Medical Association at Bristol in 1893 on a thesis "that the poison was conveyed aerially direct from the wards of the hospital." Owing to this exceptional incidence of the disease around the Leeds-road Hospital use was made of a temporary structure erected at Scholemoor, and on this being ready all subsequent cases of the disease were removed thither. From this time the incidence of the disease around the Leeds-road Hospital began to abate. Unfortunately a disastrous fire, which our readers may remember, occurred at Scholemoor, and the cases had to be returned to Leeds-road—a step which led to a considerable extension of the disease. The structure at Scholemoor was, however, rebuilt and used again for the isolation of small-pox, the outbreak shortly after coming to an end. After this experience the corporation of Bradford seriously turned their attention to the acquisition of a site for a small-pox hospital which should be remote from at least their own population, and they have now acquired a piece of land some twenty-eight acres in extent in an isolated position, where they propose to erect a hospital for the reception of patients suffering from small-pox alone. It should be mentioned to the credit of Bradford that a few years ago the authorities expended a considerable amount of money in an endeavour to provide a small-pox hospital on the lines suggested by the Royal Commission on Small-pox and Fever Hospitals—i.e., one in which all the outgoing air should be sterilised. It is, however, much to be regretted that this experiment was unsuccessful, and the special apparatus provided has now, we believe, been demolished. There were in all 935 cases of small-pox

Digitized by Google

treated in the Leeds-road Fever Hospital, and the protection afforded by vaccination may be gathered from the following table:—

		Deaths.	Death-rate.
All cases	935	100	10·7 per cent.
Vaccinated cases ...	706	36	5·1 ,,
Doubtful cases ...	34	9	26·5 ,,
Unvaccinated cases	195	55	28·2 ,,

From these figures Dr. Evans points out that "(1) if the unvaccinated had died only at the rate of those vaccinated there would have occurred, not 55 deaths, but 10 deaths; (2) if the vaccinated had died at the rate of those unvaccinated there would have been, not 36, but 193 deaths; (3) if all the patients had been vaccinated there would have been only 48 deaths instead of the 100 deaths actually recorded; (4) if all the patients had been unvaccinated there would have occurred 264 deaths in place of the 100 deaths actually recorded."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 5785 births and 3644 deaths were registered during the week ending Dec. 7th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 22·1 to 17·9 per 1000, was again 17·9 last week. In London the rate was 17·3 per 1000, while it averaged 18·4 in the thirty-two provincial towns. The lowest rates in these towns were 10·0 in Croydon, 10·9 in Derby, 11·3 in Brighton, and 12·6 in Huddersfield; the highest rates were 20·7 in Wolverhampton, 23·5 in Manchester, 23·7 in Blackburn, 27·3 in Salford, and 28·9 in Liverpool. The 3644 deaths included 561 which were referred to the principal zymotic diseases, against 548 and 529 in the two preceding weeks; of these, 207 resulted from measles, 109 from diphtheria, 80 from whooping-cough, 66 from "fever" (principally enteric), 54 from scarlet fever, 41 from diarrhœa, and 4 from small-pox. No fatal case of any of these diseases occurred last week in Croydon, Derby, or Huddersfield; in the other towns they caused the lowest death-rates in Swansea and Sunderland, and the highest rates in Manchester, Wolverhampton, Liverpool, Blackburn, and Salford. The greatest mortality from measles occurred in Liverpool, Manchester, Oldham, Salford, and Blackburn; from scarlet fever in Gateshead; from whooping-cough in Bradford; and from "fever" in West Ham, Norwich, Birkenhead, and Newcastle-upon-Tyne. The 109 deaths from diphtheria included 69 in London, 5 in Liverpool, 4 in Wolverhampton, 4 in Birmingham, and 4 in Manchester. Two fatal cases of small-pox were registered in West Ham, 1 in London, and 1 in Oldham, but not one in any other of the thirty-three large towns. There were 87 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 7th inst., against 86, 89, and 79 at the end of the three preceding weeks; 18 new cases were admitted during the week, against 23, 20, and 9 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2805, against 2845, 2807, and 2799 on the three preceding Saturdays; 312 new cases were admitted during the week, against 298, 296, and 325 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 447 to 285 in the four preceding weeks, further fell to 264 last week, and were 194 below the average. The causes of 58, or 1·6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Oldham, Bradford, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Birmingham, Liverpool, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the four preceding weeks from 21·4 to 17·4 per 1000, rose again to 19·5 during the week ending Dec. 7th, and was 1·6 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·2 in Leith and 15·4 in Perth to 24·1 in Aberdeen, and 24·4 in Dundee. The 562 deaths in these towns included 21 which were referred to diarrhœa, 19 to whooping-cough, 10 to diphtheria, 8 to scarlet fever, 6 to measles, 3 to "fever," and not one to small-pox. In all, 67 deaths resulted from these principal zymotic diseases, against 48 and 49 in the two preceding weeks. These 67 deaths were equal to an annual rate of 2·3 per 1000, which was 0·5 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The 21 fatal cases of diarrhœa showed a further increase upon those recorded in recent weeks, and included 5 in in Glasgow, 5 in Edinburgh, and 5 in Dundee. The deaths referred to whooping-cough, which had been 10 and 11 in the two preceding weeks, further rose to 19 last week, of which 12 occurred in Glasgow and 4 in Aberdeen. The fatal cases of diphtheria, which had been 3 and 6 in the two preceding weeks, further rose to 10 last week, and included 6 in Glasgow. The 8 deaths from scarlet fever corresponded with the number in the preceding week, and included 4 in Aberdeen and 2 in Glasgow. The 6 fatal cases of measles exceeded the number recorded in any recent week, and included 3 in Greenock and 2 in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 123 and 107 in the two preceding weeks, rose again to 132 last week, but were 37 below the number in the corresponding week of last year. The causes of 32, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 23·1 to 25·1 per 1000, declined again to 20·1 during the week ending Dec. 7th. During the past ten weeks of the current quarter the death-rate in the city has averaged 24·1 per 1000, the rate during the same period being 18·1 in London and 17·4 in Edinburgh. The 135 deaths registered in Dublin during the week under notice showed a decline of 33 from the number in the preceding week, and included 6 which were referred to the principal zymotic diseases, against 10 in each of the two preceding weeks; of these, 2 resulted from whooping-cough, 2 from diarrhœa, 1 from small-pox, 1 from "fever," but not one either from measles, scarlet fever, or diphtheria. These 6 deaths were equal to an annual rate of 0·9 per 1000, the zymotic death-rate during the same period being 3·0 in London and 1·3 in Edinburgh. The 2 fatal cases of whooping-cough corresponded with the number recorded in the preceding week. The deaths referred to different forms of "fever," which had been 2, 3, and 4 in the three preceding weeks, declined again to 1 last week. The 135 deaths in Dublin last week included 29 of infants under one year of age, and 29 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons were below those recorded in any recent week. Three inquest cases and 4 deaths from violence were registered; and 55, or more than a third, of the deaths occurred in public institutions. The causes of 8, or nearly 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during November in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 13·8 per 1000 of the population, estimated at 4,392,346 persons in the middle of the current year. In the three preceding months the rates had been 9·9, 12·4, and 14·5 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Hammersmith, St. George Hanover-square, Westminster, Stoke Newington, St. Olave Southwark, and Bermondsey; while they showed the largest excess in Chelsea, Hackney, Bethnal Green, Limehouse, Mile End Old Town, Poplar, and Greenwich. The prevalence of small-pox in London showed a marked decline during November, the 32 cases notified during the month including 7 in Camberwell, 5 in Greenwich, 4 in Poplar, and 3 in Limehouse sanitary areas. The Metropolitan Asylum Hospitals contained 73 small-pox patients at the end of November, against 331, 227, and 103 at the

end of the three preceding months; the weekly admissions averaged 15, against 57, 27, and 15 in the three preceding months. The prevalence of scarlet fever in London showed a decline during November; this disease was proportionally most prevalent in Chelsea, Hackney, Holborn, Bethnal Green, Whitechapel, Limehouse, Lambeth, and Battersea sanitary areas. The Metropolitan Asylum Hospitals contained 2690 scarlet fever patients at the end of November, against 2435, 2845, and 2727 at the end of the three preceding months; the weekly admissions averaged 304, against 292, 333, and 263 in the three preceding months. The prevalence of diphtheria in London during the month under notice almost corresponded with that in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Chelsea, St. Martin-in-the-Fields, Mile End Old Town, Poplar, and Greenwich. There were 672 diphtheria cases under treatment in the Metropolitan Asylum Hospitals at the end of November, against 666, 664, and 661 at the end of the three preceding months; the weekly admissions averaged 98, against 80, 101, and 103 in the three preceding months. The prevalence of enteric fever in London showed a very slight decline from that recorded in the preceding month; this disease was proportionally most prevalent in Chelsea, Hackney, St. Martin-in-the-Fields, Strand, and Holborn sanitary areas. Erysipelas was proportionally most prevalent in St. Giles, St. Luke, Bethnal Green, Whitechapel, and Rotherhithe sanitary areas. The 20 cases of puerperal fever notified during November included 4 in Islington, 2 in Fulham, 2 in Lambeth, and 2 in Battersea sanitary areas.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Nov. 30th, the deaths of 6131 persons belonging to London were registered, equal to an annual rate of 18·2 per 1000, against 16·9, 16·0, and 17·5 in the three preceding months. The lowest death-rates during November in the various sanitary areas were 11·3 in Hampstead, 11·6 in Wandsworth, 13·4 in St. George Hanover-square, 14·1 in Lewisham, (excluding Penge), 15·2 in Woolwich, 15·4 in Battersea, and 15·8 in Kensington and in St. James Westminster; the highest rates were 23·0 in St. Pancras, 23·3 in Bermondsey, 24·0 in St. George Southwark, 24·7 in Clerkenwell, 25·0 in St. Saviour Southwark, 25·1 in City of London, 26·2 in St. Luke, and 26·8 in Newington. During the four weeks of November 953 deaths were referred to the principal zymotic diseases in London; of these, 377 resulted from measles, 265 from diphtheria, 80 from diarrhœa, 77 from scarlet fever, 77 from enteric fever, 74 from whooping-cough, 2 from small-pox, and 1 from an ill-defined form of fever. These 953 deaths were equal to an annual rate of 2·8 per 1000; the lowest zymotic death-rates were recorded in Hampstead, Stoke Newington, Whitechapel, Limehouse, St. Saviour Southwark, and Woolwich; and the highest rates in St. Pancras, St. Martin-in-the-Fields, Clerkenwell, St. George Southwark, Newington, and Bermondsey sanitary areas. Two fatal cases of small-pox were registered in London during the month under notice, slightly exceeding the corrected average in the corresponding periods of the ten preceding years; of these 2 deaths, 1 belonged to Newington and 1 to Camberwell sanitary areas. The 377 deaths referred to measles were 167 above the corrected average; among the various sanitary areas this disease showed the highest proportional fatality in St. Pancras, Clerkenwell, Bethnal Green, St. George Southwark, Newington, Bermondsey, and Camberwell. The 77 fatal cases of scarlet fever were 31 below the corrected average; this disease showed the highest proportional fatality in St. Pancras, Holborn, Rotherhithe, and Lewisham sanitary areas. The 265 deaths referred to diphtheria were 105 above the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Kensington, Chelsea, Bethnal Green, Poplar, Greenwich, and Lee. The 74 fatal cases of whooping-cough were 64 below the corrected average; this disease showed the highest proportional fatality in Kensington and Hackney sanitary areas. The 77 deaths referred to enteric fever slightly exceeded the corrected average number; among the various sanitary areas the highest proportional fatality of "fever" was recorded in Hackney, Clerkenwell, Poplar, Greenwich, and Plumstead sanitary areas. The 80 fatal cases of diarrhœa were 12 above the corrected average; this disease was proportionally most fatal in St. George Southwark and Bermondsey sanitary areas. In conclusion, it may be stated that the mortality in London during November from these principal zymotic diseases was nearly 13 per cent. above the average.

Infant mortality in London during November, measured by the proportion of deaths under one year of age to registered births, was equal to 140 per 1000, and was slightly below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Paddington, St. George Hanover-square, St. James Westminster, Marylebone, Limehouse, and Woolwich; and the highest rates in Westminster, St. Martin-in-the-Fields, Holborn, Clerkenwell, St. Saviour Southwark, and St. George Southwark.

THE SERVICES.

MOVEMENTS OF MEDICAL STAFF.

THE following officers have embarked for a tour of service in India:—Surgeon-Lieutenant-Colonel Miller and Surgeon-Major Kerin. Surgeon-Colonel Maxham has arrived at the Cape and taken over the duties of Principal Medical Officer. Brigade-Surgeon-Lieutenant-Colonel Duke and Surgeon-Captains Manders, Hale, and Hayman have arrived in Ceylon. The following officers have arrived from India on completion of a tour of service:—Surgeon-Lieutenant-Colonel Quill and Surgeon-Majors Carleton and Barrington.

ARMY MEDICAL STAFF.

Surgeon-Major-General James Inkson, M.D., is placed on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are announced:—1st Bombay Grenadiers: Surgeon-Lieutenant Moore to officiate in Medical Charge. 2nd Bombay Lancers: Surgeon-Lieutenant Leumann to officiate in Medical Charge. Surgeon-Captain P. W. O'Gorman, Officiating Civil Surgeon of Midnapur, is appointed to act as Civil Surgeon of Singhbum. Surgeon-Captain B. H. Dean is appointed to do general duty at the Bengal Presidency. Surgeon-Captain J. G. Hojel is appointed to be Resident Surgeon, St. George's Hospital, Bombay.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Staff-Surgeon T. E. H. Williams to the *Flora*. Surgeons: S. W. Johnson, M.B., to the *Melita*; and H. F. Iliewicz to the *Flora*, and after to the *Pelican*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Joseph W. Hodgson, M.D., to be Surgeon-Major. Surgeon-Lieutenant James Taylor, M.D., 6th Volunteer Battalion the Gordon Highlanders, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Northumberland Fusiliers: Surgeon-Captain W. B. Mackay, M.B., to be Surgeon-Captain. 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Captain R. S. Gibb, M.B., to be Surgeon-Major, and Surgeon-Lieutenant J. L. Wilson, M.B., to be Surgeon-Captain. 2nd Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Major W. Hammond resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry): William Henry Hender Bennett, M.B., to be Surgeon-Lieutenant.

THE HEALTH OF THE SOLDIER IN WESTERN EUROPE.

Dr. F. Antony, a French military surgeon, has published in the *Archives de Médecine et de Pharmacie Militaires* (tome xxvi., page 142) some very interesting statistical information regarding sickness and mortality in the various armies of Western Europe. The amelioration that has taken place in the vital condition of the soldier during the last thirty years is most remarkable and far exceeds anything of the kind observable in civil life. Everywhere the figures adduced by the compiler denote improvement; but although it is difficult, if not impossible, to institute a perfectly exact comparison between the several countries on account of the different systems in force, we nevertheless note

Digitized by Google

with satisfaction that the advance in salubrity is in no case so well marked or so steady as with us. When considering military mortality (in time of peace) from a comparative point of view there are, according to Dr. Antony, two chief factors which the observer must bear in mind: in the first place, the numerical proportion borne by the armies to the total population; and, secondly, the amount of invaliding. France, for instance, keeps up a force equal to that of Germany, whereas the latter country is the more populous by a quarter, and German medical officers are consequently able to exercise greater discrimination in the selection of recruits. This power to pick and choose is better marked in Austria, where the troops are not half as numerous as in France, and better still in England, where scarcely 100,000 men in all are enrolled beneath the colours. The influence of free invaliding on the death-rate is, of course, obvious. Doubtless Dr. Antony's arguments are sound to a certain extent, but as regards England it should not be forgotten that we have no conscription, and that suitable recruits are not easy to find. Of late matters in this respect have somewhat improved, but, especially in the line, there is still difficulty in securing a sufficiency of eligible youths. The following hospital statistics are interesting as far as they go. To render the information complete the number of men treated *à la chambre* should be shown. 1880-90, admissions to hospital per annum per 1000 of strength at beginning and end of decade: France, 612—618; Germany, 1172—897; England, 829—810; Austria, 995—891; Italy, 833—796. Dr. Antony's statistics of death and invaliding are more elaborate and must represent a vast amount of labour on his part. His final remarks on the subject are noteworthy. "What conclusions are to be drawn from this compilation? It is an incontestable fact that the soldier has a threefold better chance of living now than he had thirty years ago, so long, that is, as he remains in the ranks. It is none the less true, however, that eliminations on account of ill-health have gone up in a corresponding ratio, save as regards the English army, where all figures are indicative of continuous regression. For the other nations the results obtained are perhaps favourable, but approbation in their case cannot be unreservedly given."

,, 1891	10·06	28·5

It is impossible to fill up the invaliding column in the case of Austria, because men sent on temporary sick leave are inextricably mixed with those who are permanently disabled. This observation also applies in a measure to Belgium and Italy.

THE ASHANTI EXPEDITION.

There is not very much to chronicle in regard to the forthcoming expedition to Ashanti. Some of the British troops from this country have already arrived at the Gold Coast, and the Special Service Corps, with a large draft of the Army Hospital Corps, some officers and men of the Royal Engineers, and others embarked on Saturday last for Cape Coast Castle, after having been inspected by the Commander-in-Chief. Lord Wolseley, accompanied by several officers of the headquarters staff, Sir William Mackinnon, the Director-General of the Army Medical Department, and others, visited the *Coromandel*, which is understood to be admirably fitted up with every comfort and convenience. Great activity prevails at Cape Coast Castle. Four thousand native carriers selected from various tribes have already started from Prahsu, about eighty miles distant from the base, all stores having, by Sir Francis Scott's order, to be forwarded there. It is understood that arrangements have been, or are being, made for 10,000 native carriers altogether. The 2nd West Yorkshire Regiment, stationed at Gibraltar, have embarked on board the steamer *Manila* for the West Coast of Africa, where the corps joins the Ashanti Expedition. Great care and attention have been bestowed on the details connected with the equipment of the force and upon the military and medical arrangements of the present expedition based upon the experience obtained in the previous operations which took place twenty-two years ago. The total cost of the last expedition was altogether about £900,000. Among the officers who embarked for Ashanti in the *Coromandel* were Surgeon-Lieutenant-Colonel Blennerhassett, Surgeon-Major Wolseley, Surgeons-Captain O'Callaghan, H. A. Cummins, W. C. Beevor, J. F. G. Burke, G. Wilson, and Hilliard, and Surgeon-Lieutenant C. G. Spencer. The *Coromandel* is expected to arrive at Cape Coast Castle on Christmas Day.

The *Army and Navy Gazette* says: "Some seem to regard the present Ashanti expedition as a very insignificant little affair. Now it may or may not be. Certainly there is one enemy to be fought—viz., a very trying and pestilential climate. In the Ashanti War, under Lord Wolseley, the mortality did not cease at the time of the war, for after leaving the country, within a given period of four months, it is put down to 3·14 per cent. of the strength disembarked. So likewise the present expedition will have results after leaving the country as well as during its stay there."

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The sixteenth distribution of prizes of the school took place at a concert held in the Banqueting Hall, Crosby Hall, E.C., on Saturday, Dec. 7th. The prizes were distributed by Lieutenant-General Moncrieff, and the president of the school, Major Andrew Maclure, occupied the chair. Major Maclure, in speaking of the work of the school during the past year, said that the classes generally had been well attended; a large number had obtained proficiency certificates, bringing up the number of officers who had thus qualified for promotion to close upon 200. Officers from the colonies, including Australia and the Cape of Good Hope, had also joined for courses of instruction. A new feature in the work with regard to first aid classes had been the introduction of lectures on nursing and duties in military hospitals. Lieutenant-General Moncrieff, in presenting the prizes, congratulated the team of the London Rifle Brigade on having carried off by the narrow margin of one point the handsome Challenge Bowl presented to the school by Surgeon-Major-General J. B. Hamilton, M.D., late principal medical officer, Home district. Surgeon-Major H. F. Stokes, chief instructor, also spoke and testified to the able support which he had received from the staff of the school. A capital concert terminated the proceedings. The next class for the training of regimental stretcher-bearers will be held at the headquarters of the "Artists" R.V., commencing at 7.30 P.M. on Wednesday, Feb. 5th.

THE ITALIAN FORCE IN ABYSSINIA.

If the accounts of the Italian reverse in Eastern Africa and of the threatening attitude of a very large advancing Abyssinian army be not exaggerated, General Baratieri's force will require to be at once largely reinforced by troops from Italy. The fighting at Ambalagi appears to have been very severe and to have been mainly brought about by that over-confidence which characterised some of our own movements in Egypt and the Soudan. A detached native force advancing under the command of Italian officers was surprised by a vastly superior number of the Shoan army and compelled to retreat. Later telegrams from General Baratieri, it is stated, allege that Abyssinian forces have

Digitized by Google

invaded the Tigre country and besieged Makalle and Antalo. We have heard nothing of the field medical service now in Abyssinia at the disposal of the Italian force, but it is clear that a number of medical officers, together with hospital stores and equipment, will be required, and these, no doubt, will be sent out with the reinforcements to be despatched by the Italian War Office.

DEATHS IN THE SERVICES.

Surgeon-Colonel Daniel Charles Grose, principal medical officer, North British military district at Edinburgh, on the 7th inst., in his fifty-fifth year. He entered the Army Medical Service in 1864, and in 1865–66 served with the expedition from Aden into the interior of Arabia, was in medical charge of the force at the action of Bir Said, and was present at the subsequent operations. He became a surgeon-major in 1876 and brigade-surgeon in 1890.

THE PASTEUR INSTITUTE FOR INDIA.

Surgeon-Colonel C. Roe, I.M.S., has been appointed honorary secretary of the association for the foundation of a Pasteur Institute in India. It is understood that sufficient funds have been collected to assure the success of the scheme.

Sir William Mackinnon, the Director-General of the Army Medical Service, was recently at Windsor Castle on a visit to the Queen.

On Dec. 3rd 170 invalids arrived at the Royal Victoria Hospital, Netley, from Bombay, *ex* hired transport *Dilwarra*.

Correspondence.

"Audi alteram partem."

"THE CASE OF DR. WIGHT."

To the Editors of THE LANCET.

SIRS,—I was pleased to read your editorial article and also "M.D.'s" letter in THE LANCET of Dec. 7th. I concur entirely with both, and as there appears a possibility of a doubt, Dr. Wight should have had the benefit. Ever since I read the account of the inquest in the daily press of the unfortunate case I have been on the look out for the *post-mortem* report of the injuries, which in my opinion should certainly have been communicated to the medical press, so that the profession might have had an opportunity of forming their own conclusions from a scientific account of the case. No matter how intelligent twelve laymen may be, they are incapable of forming a true opinion from post-mortem details. In this lamentable case it is unfortunate that no evidence was produced for the defence, and if the injury was situated in the posterior vaginal fornix, as stated in your leading article, there is every reason to believe that the rupture was accidental; if the rupture had been lateral, then one could understand how the blade of a forceps would, when carelessly employed, cause the fatal mischief. I take it that very few men have seen such an unfortunate occurrence, and having seen two cases myself I may be pardoned for trespassing on your valuable space. My first case happened in 1878, when I was engaged to attend a multipara whom I had delivered with difficulty some years before. As I had not been paid I said I should require my fee before I went to her again. I heard no more about the case till one morning in September, about 2 A.M., I was called with the message that Dr. C—— required my aid at once. I went, and found my neighbour, who had just succeeded to a practice, had been in attendance some time. She had been in labour several hours, and he had had forceps on and off for two hours, the forceps slipping off each time he tried to bring down the head. I examined her and found an antero-posterior diameter of three inches. I tried the same forceps and then tried my own, but they slipped off. I examined carefully again, and found what seemed to be the head well down, and beyond could feel something like the tip of the shoulder. I went for the perforator and crotchet, and was only away a very short time. On my return I found the head had receded and the fœtus was in the peritoneal cavity. Introducing my hand carefully into the vagina I found it passed through a rent in the posterior fornix or Douglas's pouch, and the uterus was completely separated; I got the feet and succeeded in delivering her in a few minutes. She survived her delivery for thirty-six hours. When did the laceration take place in this case, and who was to blame? We did our best to deliver her, and did not use more force than I used on the previous occasion. The rupture was caused no doubt through trying to bring the head through too narrow a brim, but who would venture on craniotomy before an attempt with the forceps? I feel somewhat strongly, therefore, in Dr. Wight's case that the misfortune which has happened should be put down to criminal neglect when I could understand even the anxiety of such a case causing him to have a dazed appearance. I trust something may be done to lighten the poor man's punishment, because the stigma of being held criminally responsible for what after all may only have been an unavoidable accident must be great in the case of a man who has practised honourably for thirty years.

I am, Sirs, yours faithfully,

Wigan, Dec. 9th, 1895. W. BERRY, F.R.C.S. Irel.

To the Editors of THE LANCET.

SIRS,—Without going into the merits or demerits of this unfortunate case, there is one thing which is not mentioned either in your article or in "M.D.'s" letter—viz., the apparent unfairness of the prosecuting counsel, when opening the case, in drawing the attention of the jury to the fact that the defendant was "more than half an hour" getting the forceps into apposition, thereby implying that such delay was a sign of want of knowledge or κῦδος in the operation. Now it is a well-known fact with obstetricians that in certain cases, especially where the presenting head is a fixture and the pains well-nigh continuous, it is utterly impossible to apply the forceps *cito* and at the same time *tuto et jucunde*, and that the very length of time in applying them may be but a witness of care and of scientific knowledge in the operation.

I am, Sirs, yours fathfully,

W. L'HEUREUX BLENKARNE,
Surgeon to the Leicester Provident Dispensary.

Leicester, Dec. 10th, 1895.

SEQUEL TO A CASE OF TRAUMATIC TETANUS TREATED WITH TETANUS ANTITOXIN.

To the Editors of THE LANCET.

SIRS,—When sending you the notes of my case of traumatic tetanus treated with tetanus antitoxin[1] I had to record that the latest news of the child still mentioned some lameness. This has been since accounted for satisfactorily, though, I confess, unexpectedly, by the removal from the foot of a small triangular piece of china three-eighths of an inch in its longest diameter. The mother of the child writes that "on Friday (Oct. 25th) she complained of the foot being very painful. I examined it and saw a small white thing in the middle of the wound. I tried to take it out with a needle but could not, so put on a poultice of linseed and a little soda, and it took out a small piece of the dish that her foot was cut with at the beginning." As Dr. Neil Fullarton and myself both sought repeatedly with a probe for any foreign body without success, and as the wound had been well poulticed for some days until it assumed a healthy appearance, I was scarcely prepared for this sequel and was, therefore, glad to receive the enclosed letter from Dr. Fullarton.

I am, Sirs, yours faithfully,

Harley-street, W., Dec. 9th, 1895. NESTOR TIRARD.

Dr. Tirard. Blairbeg House, Lamlash, Arran, N.B., Nov. 11th, 1895.

Dear Sir,—I was up Corrie way the other day and looked in to see the little girl, K. W——, who is looking extremely well. No one would ever suppose she had so recently been through such a serious illness judging by her present appearance. You know, of course, about the piece of dish which came out of the wound, and which has apparently been retained under the tendon of the flexor longus pollicis, judging from the part of the wound it came out of, and also from the fact of it only moving out when the child began to use the foot. I am sure you must have been gratified, as I was, with the result of your treatment. I send you this note as I am sure you will be glad to learn of your little patient's complete recovery to health and strength, which she undoubtedly owes to you.

With warmest regards, believe me, yours truly,

NEIL FULLARTON.

THE CAUSE OF GOITRE.

To the Editors of THE LANCET.

SIRS,—I have read with great interest, in THE LANCET of Nov. 9th last, Dr. Gordon Holmes's remarks on the pathogenesis of sporadic goitre. It is curious that, so far as I have read on this subject in the text-books and in the various articles in the medical papers, I can find no reference to the observations of Dr. J. Saint-Leger on the cause of goitre. In his book—"Études sur les Causes de Crétinisme et du Goitre Endémique," published in Paris in 1867—there are some very interesting and carefully worked out observations on the origin of these diseases. He passes in review the various supposed causes and brings forward conclusive evidence against them. He traces the close connexion between goitre and cretinism, and maintains that the number of cretins free from goitre has been greatly exaggerated, pointing out that among cretins there is found a form of goitre which shows very little externally, the swelling of the gland developing laterally and under the muscles; he also adds that *all* cretins labour under embarrassed respiration as if from a mechanical obstruction. I may mention that we found among some of the cases of goitre operated on during my period of residence at the Cumberland Infirmary that the disease showed very little externally, but had grown under the muscles, and in two cases the growth was found embracing the trachea, and the greater part was found posteriorly. As to the cause of goitre, Dr. Saint-Leger maintains that it is found in the drinking water, and after an exhaustive research into the geological formation of the goitrous districts he came to the following conclusions. 1. That endemic goitre coincides with metalliferous soils. 2. That the chief goitre-forming element is sulphide of iron or iron pyrites. This is the most abundant and most frequent element, and the only one which is never absent. 3. That next in order of frequency comes copper pyrites (the double sulphide of copper and iron), and then, but less frequently, the sulphides of lead, arsenic, and antimony.

In support of this contention he brings forward most convincing arguments. It is the small dose of the sulphides frequently repeated that causes the disease. In three mice to which for three months he gave in their food small doses of sulphide and sulphate of iron, he produced very marked swelling of the thyroid, and in others to which were administered other supposed goitre-forming substances no such effect was produced. A very striking instance he quotes from Mr. Clelland's observations:—"In the year 1831 two companies of the 30th Regiment of Native Infantry were placed in garrison at Lohooghal, while two other companies were stationed at Petoragur, a station to the north of Lohoogha having precisely the same altitude and mean temperature as the latter. At the end of three years there was not a single case of goitre at Lohooghal, while at Petoragur there were fifty. The water for the supply of the former station came from the metamorphic clay schist, while that for the latter came from metalliferous limestone containing beds of schist with graphite and iron and copper pyrites."

Another convincing proof brought forward by Dr. Saint-Leger was as follows. Knowing the geological formation of certain districts of France he marked on the map the localities in which there ought to be goitre and then visited them. He found no goitre in the districts where he did not expect to find it, but he did not find goitre in all the places he expected, but in these cases he found that the water-supply was either got from a different formation at a distance or from wells sunk in beds of transported alluvium covering the real geological formation. In all the other districts he found the disease. These observations are very interesting and require more working out in this country. I am at present endeavouring to find out their truth as regards Cumberland and Westmorland, and hope to communicate the results of my research at some future date. Goitre is endemic here, and it is well known that n the mountains of the Pennine range—and, indeed, in other hills in these counties—iron, copper, and lead are found in large quantities, and it would be interesting to find out if these metals are found in other goitrous districts in the country. With regard to Dr. Holmes's remarks on predisposing causes of goitre, my experience here bears out the fact that the disease is most prevalent in females and that it develops generally at puberty, though in some cases in early childhood. I have seen several cases of mother and daughter being affected with the disease. It is interesting to mention, in conclusion, that Paracelsus and other physicians of the sixteenth and seventeenth centuries accused metallic waters of causing the neck to swell, and even mention iron pyrites as a cause of goitre.

I am, Sirs, yours truly,
LOUIS E. STEVENSON, M.B., B.C. Cantab.

Penrith, Nov. 12th, 1895.

"'RETURN' CASES OF SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—A record of the following history, which occurred in my practice some two years ago, may be of interest in showing that subsequent cases of scarlet fever occurring in a family cannot always be interpreted as "return" cases.

A boy at school here had scarlet fever, and when free from infection, as I considered, he returned to his home in Ireland. He having one sister at home who was young and very delicate, his parents resolved that he should go somewhere in the country before joining the family, for prudential reasons. Within three days of his leaving my care the sister fell ill with scarlet fever, although there had been no communication with the convalescent. Now, had the convalescent returned to his home I should doubtless have inferred that the sister's illness was a "return" case of scarlet fever, whereas I have little doubt that she contracted her scarlet fever by travelling in a tramcar within four days of falling ill. It was known that there was scarlet fever in the town in which she resided. In my opinion some of these "return" cases of scarlet fever are doubtless freshly contracted cases arising from travelling in public conveyances—railway carriages, cabs, and tramcars—which are the most infectious of all places—certainly they cause me great trouble. Within the last six months I have traced two cases to travelling in railway carriages, one while travelling to a football match, the other to a funeral.

I am, Sirs, your obedient servant,
Rugby, Dec. 6th, 1895. CLEMENT DUKES.

"'TUBERCULOUS' *vel* 'TUBERCULAR'?"

To the Editors of THE LANCET.

SIRS,—Among your annotations in THE LANCET of Dec. 7th there is one under the above heading. The difficulty and perplexity therein mentioned have long been recognised, and I have publicly and privately suggested a very simple and, to my mind, perfectly satisfactory solution—viz., the use of the word "nodule" for the representation of an object otherwise capable of being called a small lump, and the correlative "nodular" or "lumpy." As you say, custom has hallowed and made inviolate the noun "tubercle," and I would suggest that the time has now arrived when tubercle, tuberculous, tubercular, &c., should be gracefully yielded up to the power of a specific bacillus, and only used to connote its activity, past or present. The old order changeth, giving place to the new, and I maintain that what was excusable in an anatomist in years gone by, to apply the term "tubercle" to any small lump, cancerous, sarcomatous, or of unknown origin, is now no longer so since an all-powerful bacillus has seized upon it for its own. If my suggestion be accepted confusion cannot arise, for if the bacillus be not actually searched for we can still say "a nodule was found (? tubercular)." About three-fourths of the literature of consumption would never have obscured our eyesight, physically and mentally, had the simple words nodule and nodular but been used in the place of tubercle and tubercular where doubt was in the mind of the writer as to the presence or absence of the bacillus.

I remain, Sirs, yours truly,
Christopher-street, E.C. FRED. J. SMITH.

A CASE OF NYSTAGMUS ARISING FROM AN UNUSUAL CAUSE.

To the Editors of THE LANCET.

SIRS,—On reference to text-books I find the causes of nystagmus, or involuntary oscillation of the eyeballs, to be divided into two classes according to the age at which the symptom manifests itself—namely, in early or in adult life. The causes in early life are congenital cataract, corneal ulcer and atrophy of the choroid; whilst in adults, miner's nystagmus and that occurring in locomotor ataxy are the

Digitized by Google

usual forms given. In the case in question it was whilst attending one of the children that I first saw the father, who is a gardener, and noticed that he had nystagmus. I inquired whether he had ever been bothered with his eyes and obtained the following history. Up to the age of twenty-two his eyes were perfectly normal. One evening he was stoking the greenhouse fires and some unignited gas must have accumulated, for on opening the stove doors there was a burst of flame, which scorched his hair and face, and from the effects of which he was laid up for a fortnight. On getting about again he found he could not see as well as before on account of the movement of his eyeballs, and his friends all noticed the change in them. He is now forty-three years of age and tells me he can read perfectly both by daylight and artificial light, and that his eyes do not bother him in the least except in bright sunlight, when he becomes rather "dazed." On examination I find he has horizontal nystagmus, that both eyes act together, and that their movements are perfect in all directions. The oscillation still continues, but is reduced to about 120 a minute, when the eyes are extremely turned either inwards or outwards. The corneæ are clear, and no abnormal signs can be seen about either eye. The pupils act well both to light and to accommodation. With the ophthalmoscope I find the lenses transparent and without any signs of opacity. The discs are slightly injected, but otherwise normal. By retinoscopy + 3 corrects the left eye and + 4·5 the right eye. I have not attempted any treatment, not quite seeing what course to follow, as the nystagmus is now of twenty-one years' standing, and the subject is in perfect health and according to himself has "never had a day's illness." With regard to the pathology I am also at a loss, but suggest that changes have taken place in the nerves or nerve endings in the ocular muscles, due to peripheral neuritis caused by the inflammation consequent on the burns received twenty-one years ago.

The course of reasoning I have pursued is as follows. If a child be born blind and continue so, nystagmus generally supervenes because one of the first acquired coördinate actions is that of the harmonious and accurate movements of the muscles of the eyes, whereby the child learns to look at an object, nystagmus being therefore a defect of coördination. Now the mechanism of coördination is: (1) sensory paths for perception and conduction of impressions; (2) receiving central ganglia; and (3) efferent nerves to carry impulses from centres to motor structures. Failure of coördination may arise from defect in any one of these three structures, for in locomotor ataxy we find the change in the sensory structures, in cerebellar disease it is in the central ganglia, whilst in multiple sclerosis the lesion is in the motor paths. Miner's nystagmus, being due to excessive use and straining of the ocular muscles, is an example of lesions in the motor paths. Nystagmus occurring in locomotor ataxy is due to sensory changes. May not the nystagmus in the case under consideration be due to changes in the nerve endings in the muscles, but whether sensory or motor, or both, I cannot say?—I am, Sirs, yours truly,

A. DUNLEY OWEN, M.R.C.S., L.R.C.P. Lond.

Northampton, Dec. 9th, 1895.

*** This case is one of exceptional interest. There are many other affections besides those mentioned by our correspondent with which nystagmus may be associated, as, for example, with errors of refraction, especially high degrees of hypermetropia, with retinitis pigmentosa in albinos, and with disseminated sclerosis of the brain and spinal cord, with hysteria and with lead poisoning. The pathology of the case may of course be that ingeniously suggested by Mr. Dunley Owen, but we should be inclined to give another explanation to the effect that the shock of the explosion caused a small lesion of the choroid or retina at or near the fovea centralis in one or both eyes, and that the amblyopia thus produced led to the oscillation of the globes. Mr. Dunley Owen does not give the distant vision of the patient.—ED. L.

APOTHECARIES' HALL, IRELAND.

To the Editors of THE LANCET.

SIRS,—The Court of the Apothecaries' Hall, Ireland, would call your attention to an observation made in your valuable journal at page 1468 in reference to the petition presented by them to the General Council of Medical Education for the appointment of additional examiners in surgery, in which it is stated "Irish opinion was much divided on the Council." The facts are as follows:—There are in all seven Irish representatives. Two recorded their votes for the Hall. One spoke most strongly in favour of the request, but was urgently obliged to leave before voting. Two other Irish members of the Council were absent, but wrote letters expressing their opinions that the examiners ought to be granted. The two Irish votes given against the Hall were by two Fellows of the Royal College of Physicians, Ireland.

I am, Sirs, faithfully yours,

ROBERT MONTGOMERY, M.R.C.S., Secretary.

Mary-street, Dublin, Dec. 9th, 1895.

*** Our account and Mr. Robert Montgomery's are in accord.—ED. L.

MIDWIFERY TRAINING FOR STUDENTS.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to the fact that in your report of the proceedings of the General Medical Council[1] I am represented as saying that the Council have recommended that every student should be required to attend three months' practice in a lying-in hospital and conduct twelve cases of delivery under the direct supervision of a registered practitioner. The recommendation itself which I quoted is to the effect that either attendance at a lying-in hospital *or* presence at twelve midwifery cases should be required, and it is only stipulated three of the twelve should have been conducted personally under the direct supervision of a registered practitioner.

I am, Sirs, yours truly,

Mosley-street, Manchester, Dec. 9th, 1895. D. J. LEECH.

"THE ADMISSION OF WOMEN TO THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—Having to-day seen, for the first time, a letter signed "Albert Morton" in your issue of Nov. 16th, on the "Admission of Women to the Royal Colleges of Physicians of London and Surgeons of England," I beg you to allow me, though somewhat late, to comment on one passage contained in it, for an assertion that goes uncontradicted is sometimes supposed to be admitted. The paragraph is as follows:

"Dr. West justly says: 'What had women done for midwifery, which for a century and a half was entirely in their hands?' I would go a great deal further, and say that the modern medical women are doing more to degrade and lower the standard of the profession than any body of medical men have ever done, for they are at the present time seeking to attend midwifery for a fee of 5*s*., and for aught I know for even less than that. Does this show that there is any great and growing demand for the services of medical women even for members of their own sex?"

Now is Mr. Morton sure of the accuracy of his *facts?* It is always difficult to prove a negative, but I believe if anyone took the trouble to inquire he would find that no medical woman in practice in England has ever taken less than a guinea as her minimum fee for a midwifery case. Mr. Morton's mistake is probably founded on the fact that in certain maternities officered by medical women, to which a system of training for women students is attached, there exists a rule requiring the out-patients to pay 5*s. to the funds of the hospital* on registering their name for attendance, instead of receiving cards entitling them to be attended free, as is the usage of those hospitals in connexion with which men students undertake similar work. The object of the rule was partly to avoid pauperising a new district, partly to limit the number of cases undertaken, as the supply of women students is also limited. The sum of 5*s*. was fixed upon in the belief that no one could possibly mistake it for a doctor's fee. It may or may not have been judicious to adopt this change of method, but at any rate the question involved is not "Do women doctors degrade the profession by taking lower fees than men?" but do they degrade it by insisting that even students' work, when supervised by fully qualified doctors, should be to

[1] THE LANCET, Dec. 7th, 1895, p. 1474.

Digitized by Google

some extent paid for instead of given without any payment at all? I am, Sirs, yours sincerely,

MARION RITCHIE,
Hon. Sec. of Clapham Maternity Hospital and St. John's Maternity, Battersea.

Dec. 10th, 1895.

"SHOULDER BRACES."

To the Editors of THE LANCET.

SIRS,—Some years ago[1] I protested against a well-known surgeon recommending a new form of shoulder strap for stooping, &c. In THE LANCET of Nov. 23rd I find you have given, most probably inadvertently, a paragraph describing still another form of shoulder brace under the description of ——'s "Anti-stoop." The trade in these useless straps must be enormous to judge from the profuse way in which they are being advertised, just as if they were "cure-all" pills. For many years I have taught that shoulder straps do far more harm than good; employing them tends to develop the muscles which draw the scapulæ forwards, so that when the straps are left off the sufferer is more round-shouldered than ever. Allow me to quote the opinion of the late John Shaw of the Middlesex Hospital, one of the most clear-headed writers on orthopædic surgery I have come across. He says in his book:[2] "The effect which the instrument (shoulder-brace or common back collar) produces in ordinary cases may be easily comprehended. If the shoulder-blades be brought close to the spine by the straps of the brace and kept constantly so, there can be no use for the several strong muscles which pass from the spine to the shoulder-blades. They must consequently waste and become nearly useless, while those on the forepart of the chest, being excited to resist the straps, will become increased in power, and hence, when the strain is taken off, not only will the shoulders fall forward as in a delicate person, but the muscles on the forepart of the chest will predominate over those by which the shoulder-blades should be held back and pull the shoulders forwards."

I do not think any impartial surgeon would controvert John Shaw's sensible remarks written seventy years ago.

I am, Sirs, yours faithfully,

Queen Anne-street, W., Nov. 25th, 1895. BERNARD ROTH.

"THE WIDOWS OF MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—I have read the article on "The Widows of Medical Men" in THE LANCET of Dec. 7th, and beg to submit the subjoined statement. Like most of the licensed houses and registered hospitals—of which it is one—the Holloway Sanatorium receives voluntary boarders, but it does not lay itself out for them, only 37 of its 380 inmates residing as boarders at St. Ann's Heath or at the Brighton branch. Of these 37 boarders some are without means and one on the free list, others are unfitted for home care, and only a small proportion could be available for boarding with doctor's widows. In 1894 the average weekly cost of each inmate was £2 1*s.* 10*d.*, the average weekly payment now made by each boarder is only £1 11*s.* 5*d.*, which in some cases includes clothing, seaside trip, and other extras. The Holloway Sanatorium boarders are of no pecuniary advantage to the hospital, nor would they be so to G.B.R. and others like herself. The sanatorium can only accommodate 400 inmates: 279 patients and boarders were admitted in 1894, and 267 were discharged. Many of those discharged were placed, on my recommendation, in private care. If G.B.R. is a suitable person I may be able to help her.

I am, Sirs, yours faithfully,
S. R. PHILIPPS, Medical Superintendent.

St. Ann's Heath, Virginia Water, Dec. 11th, 1895.

"THE DEGRADATION OF MEDICAL PRACTICE."

To the Editors of THE LANCET.

SIRS,—Whilst endorsing on the whole your leading article on "The Degradation of Medical Practice by Commercial Companies,"[1] it must not be lost sight of that these insurance and medical societies (vulgarly called "death and the doctor" clubs) are by no means the only offenders against the well-being and honest independence of the medical profession. Take, for instance, the older friendly societies—e.g., Oddfellows, Foresters, &c.: these originally were, as they still are in some parts of the country, for the "brethren" only, but of late years the wives and children have been admitted as "dispensary" members of such societies, and that, too, without any medical examination as to their fitness to become members. This has been doubly hard on the medical profession, as formerly such wives and children were one's private patients, and the members themselves gave one very little trouble, for, as a general rule, it is an exception for a man to suffer from hysterical and fanciful ailments like a woman, or to be subject to "catching complaints" like a child, and of this nature is a large percentage of the cases which take up a medical man's time with his "dispensary" work, whether it be that of a (so-called) provident dispensary or of the "dispensary" members of the older friendly societies. I have used the words "hysterical" and "fanciful" in no invidious sense, it being self-evident that man, being out and about at his daily work and thus having more change of scene, has less time for introspection, a fruitful source of hysteria, &c., to which woman is more prone by reason of her more circumscribed environment and from the more monotonous duties of the home, which confine her so much indoors. "Man for the field, and woman for the hearth," as Tennyson has it.

I have the fortune (or misfortune?) to practise in one of the most club-ridden towns in England, so much so that there is scarcely a general practitioner in it who is not a "club doctor" of some sort or kind, even those living in the most aristocratic parts of the town not disdaining such medical—I should say pecuniary—aid to their practices, and quite half the number of practitioners are dispensary medical officers. This is, perhaps, scarcely to be wondered at when it is stated that the especial difficulty in this town is that, on the one hand, there is such a large preponderance of the artisan class of population, and, on the other hand, the number of fresh medical men starting in practice steadily increases out of all proportion to the monetary value of the population. This is altogether a most unsatisfactory state of things, and if the well-being and *amour propre* of the medical profession are to be in any way improved, or even retained, some *modus vivendi* must be arrived at. One way would be the extension of the dispensary system, only with a sliding scale of payment for members, to be arranged according to their income or to the rental of their houses. Then, again, all dispensary committees should consist either altogether of the medical officers themselves or they should have a preponderating voice in the management. By these means would be reduced to a minimum that most crying abuse of most dispensaries and clubs—viz., the want of care that generally characterises them in refusing to admit as members those who are in a position either to be private patients or at any rate to pay a much larger capitation fee than they do under the present *régime*. I remain, Sirs, yours faithfully,

Leicester, Dec. 4th, 1895. A LEICESTER PRACTITIONER.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—It is in accordance with the best traditions of THE LANCET that grievances in the profession should be freely discussed in its columns. No one in his day did more yeoman service to the profession than the level-headed, hard-hitting Founder of your journal, and the name of the one-time Doctor-Member for Finsbury and Doctor-Coroner for Middlesex should ever be remembered with respect, especially by the general practitioner of medicine. It may be questioned, however, whether it is altogether wise that the internecine misunderstandings of the profession should be so constantly dragged before the public to the amusement of the cynic and the indifferent, and to the pain of all who respect the interests and dignity of the profession. One of the most distinguished consultants of the day, himself for long a general practitioner, once remarked to the writer that in throwing mud at the profession one inevitably besmirched oneself. When a wrangle degenerates into the pot calling the kettle black we know that argument and reason have been

Digitized by Google

abandoned, and temper and abuse are in the ascendant. The grievance of the general practitioner used to be that the specialist took work from him, and more recently he seems to have discovered that he robs the public. Although, no doubt, particular instances are thus indignantly and anonymously pointed at, the impression conveyed to those not fully conversant with the circumstances is that the charge is a general one, and a profession second to none in honourable distinction is thus lowered in the eyes of the public. The secret of these misunderstandings seems to be that the altered conditions of the profession by the mere force of evolution are not sufficiently taken into account. The hard-and-fast line between the consultant and the private practitioner no longer exists. Let us free our minds from cant and recognise an increasingly palpable fact. The "consultant" has in no way degenerated from his gold-headed stick prototype, but the "visiting apothecary" of the old school is as extinct as the dodo. I do not speak of that stratum in the profession which sells what brains it has for sixpence and throws in the physic, but of the physician or surgeon in private practice. A natural consequence of the improved education and status of the general practitioner is that the purely consultant opportunities of the consultant have been very materially diminished. Is there, then, still to be a class of consultants? And if so, how are they to come into being? In the pre-Napoleonic French army a man required to have at least four generations of ennobled ancestors before he could become a candidate for commissioned rank. Is it to be required of the budding consultant of the twentieth century that he should be born in the purple or set out in life with a competent income? If not, how is he to live? Only a very limited number of men can become attached to teaching hospitals, and thus trust to the future good offices of past students; while without the material which a hospital affords no one can become worth consulting in any department except one—namely, obstetrics, in which many general practitioners are quite as much specialists as those who pose as such. This does not apply to gynæcology. Those, then, who have not assured them a former-pupil *clientèle*, and also are in a position to conscientiously regard their advice as worth having in consultation, must give evidence of it by publication—that is, by appeal to a larger professional public than that of a single school. Now, a man cannot have a consulting reputation with the profession and no reputation with the public, and if the public in the exercise of their liberty of action consult such a one *unintroduced* by a fellow practitioner, what is the consultant's duty: to shut the door in the face of this public and starve, or to practise his profession and put on weight? It is not difficult to choose between these alternatives, and no one hesitates to choose the latter unless he finds it to his advantage to do so. This situation, however, necessarily leads to friction, and how is this to be avoided? In my opinion, by ceasing to emphasise a distinction between the rank and file of the profession which is being gradually but certainly obliterated; by throwing down artificial barriers to the development of the special practitioner from the general practitioner; and by impressing the meanest member in the ranks of the profession with the belief that, like the post-Napoleonic private soldier, he potentially carries a field-marshal's baton in his knapsack. Given a fair field and no favour, it will only be a very ill-conditioned person who can object to the natural consequences of the ensuing contest. I have ventured, Sirs, to express my convictions so fully as I have had some opportunity of studying by experience both sides of the question.—I am, Sirs, yours faithfully,

Dec. 10th, 1895. IN TOTO PARS.

"THE PRIMARY EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—In Professor Fawcett's letter on this subject in THE LANCET of Nov. 23rd he makes a misleading statement when he says that two hours are devoted to Practical Anatomy at the London University examination. The actual facts are these. The candidates are each given a part to dissect for two hours, but of this two hours a quarter of an hour is spent in a *viva-voce* on bones. At the end of this time the candidates are taken to another room, whence they go in turn to another *viva-voce* in soft parts. As far as a candidate can judge, the dissection is of no use, as any man with a little skill in dissecting and less anatomical knowledge could easily perform the task. Conversation is free and unchecked all the time. As you say in your annotation, the London examination is much more severe and thorough than that of the Conjoint Board, but I do not think it is fairer to the student. How can a man do himself justice after two hours' dissecting, and perhaps another two hours' waiting in a bare and dismal room, without recreation or refreshment of any kind, and most likely in a state of extreme nervousness? Then, when he is thoroughly exhausted in mind and body, he is questioned minutely on various regions of the body. This is no imaginary picture—I speak from bitter experience. As far as a candidate can judge the time *is* limited, as every quarter of an hour a bell rings and a fresh batch of candidates takes the place of the old ones. As regards the results of the Conjoint Examinations Professor Fawcett well describes them as "startling." It is a well-recognised fact in provincial schools that it is impossible to foretell who will pass. I have known very able men, who have passed examinations quite as hard at their own universities, who have been ploughed in one or more subjects at the Conjoint examination, much to the disgust of themselves and friends.

I am, Sirs, yours faithfully,

Nov. 25th, 1895. F. S. J.

THE BATTLE OF THE CLUBS.—XIII.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1460.)

THE ROYAL VICTORIA DISPENSARY AT NORTHAMPTON.

NORTHAMPTON is distinguished among all other towns by possessing one of the largest and, in a way, one of the most successful provident dispensaries of England. Here, if anywhere, the question of club practice has been fully discussed, though it must be confessed the result is far from satisfactory. To judge from printed reports and the rules laid down there is little to complain about; but to judge from the conversations of the junior practitioners in the town the complaints are numerous and a very bitter feeling exists. The actual position of affairs can, however, only be rendered intelligible by, at least, a brief historical retrospect. The Royal Victoria Dispensary was founded in 1845 to commemorate the visit of Her Majesty the Queen to Northampton. A sum of close upon £1000 was then raised by donations; thus, in its initiation the institution was distinctly a charity. At the cost of £800 a building was purchased, and another £200 were spent to convert this house into a dispensary. Some persons then urged that medical aid should be given gratuitously to those who were too poor to join the benefit societies and the sick clubs of the town. Others maintained that this class was already well provided for by the tickets which subscribers to the General Infirmary were able to give away and by the Poor-law Union. Then it was pointed out that many respectable working men felt degraded by having to beg for infirmary tickets; that the loss of time in getting these tickets sometimes entailed great aggravation of illness or even loss of life. Again, it was stated that the wives of working men were only in one or two instances able to obtain from benefit clubs the attendance, during their confinement, of competent medical men. For these various reasons it was decided to work the institution on provident principles—that is, to make the members subscribe. Mr. John Becke, solicitor, was appointed honorary secretary, and has been throughout the most active worker in the organisation of this great institution. In several pamphlets, speeches, and documents he has defended the institution; and, in answer to the objection that it might injure the interests of the medical profession, he has expressed his

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Aug. 24th, 1895, Brussels; (2) Aug. 31st, 1895, Brussels; (3) Sept. 21st, 1895, Portsmouth; (4) Sept. 28th, 1895, Portsmouth; (5) Oct. 5th, 1895, Eastbourne; (6) Oct. 12th, 1895, Lincoln; (7) Oct. 26th, 1895, Lincoln; (8) Nov. 2nd, 1895, Grimsby; (9) Nov. 9th, 1895, Bexhill-on-Sea; (10) Nov. 16th, 1895, Hull; (11) Nov. 23rd, 1895, Hull; (12) Dec. 7th, 1895, York.

Digitized by Google

doubts that such was the case, but has added that if these interests were opposed to the well-being of a large number of the poor the interests of a higher and richer but less numerous body must give place to those of the poorer. Mr. Becke, however, and others also, contend that medical men were rarely paid by the poor they attended, and that the medical officers of the Poor-law boards received very inadequate stipends. On the other hand, by the provident system medical men would be ensured payment, and poor families would not be ruined by serious illnesses. Then diseases were aggravated and preventable deaths occasioned because many people postponed seeking medical advice till a great emergency arose. They resorted to the dispensing druggist, the advice of some friend, or to quack medicines, rather than incur the cost of proper medical attendance. Members of a provident institution could, on the contrary, and without extra cost to themselves, obtain advice early, and thus the evil might be nipped in the bud. This, also, was very advantageous to the community at large in cases of infectious disease, as there would be a better prospect of taking the necessary precautions in time to prevent the disease spreading. For these various reasons the first rule was worded as follows: "The object of this institution is to enable the working class to ensure for themselves and their families efficient medical advice and medicine during illness by their own small periodical payments, with the assistance of contributions from the more opulent. The free members shall consist of working persons and servants, their wives and children, not receiving parish relief, and being unable to pay for medical advice in the usual manner." The payment used to be 2*d*. a week for a family, 1*d*. a week for persons above and ½*d*. for those under fourteen years. Now the weekly charge is 3*d*. for families and 1½*d*. for persons above and 1*d*. for persons below fourteen years. Domestic servants pay 5*s*. a year. The fee for confinements is 10*s*.

In a pamphlet giving a history of this institution Mr. Becke relates that there was much discussion as to the number of medical men to be appointed. "The late Mr. Smith of Southam, whose opinion was certainly entitled to great respect, thought it ought to be thrown open to every medical practitioner in the town who wished to join it. I and others believed that by thus dividing responsibility we should greatly diminish the efficiency of the medical staff, that some would join simply because they did not wish to see their names omitted, but to whom the remuneration would not be an object and all labour distasteful; that if the number of officers was limited and the appointments subject to competition, only those would seek for the appointments who were anxious to obtain them and who were ready to do the work." These arguments were met by a sort of compromise, and six medical officers were elected; but in the first year one and in the second year two of them resigned. This confirmed Mr. Becke in the opinion that the number of medical men to be engaged should not be more than the institution could afford to remunerate adequately. All those who worked for the institution should make good incomes out of the work, and this end has certainly been well realised, so well, indeed, that it has caused strong dissatisfaction among the other practitioners. That the compromise described above should have proved a failure was very natural, for it could not satisfy either party. It had all the disadvantage of creating a privilege, but the privilege when obtained was not worth having. The fairest method would have been to throw the dispensary open to any fully qualified practitioner who chose to enrol himself as one of its medical officers. It would then be no special privilege or honour to be included in the list of medical officers, so that it is difficult to see why a medical man should enrol himself if he did not mean to attend the patients. But even if this had occurred in one or two instances the patients would very soon have found out those practitioners who had not their hearts in the work. A little experience would have shown who were the medical officers to whom this club practice was of consequence and who were prepared to give it the necessary time and attention. Young and energetic men would then have had a fair chance of coming to the front, and could not complain that a privileged monopoly has been created. It is true that in those days it was not foreseen that the institution would grow to its present size and importance. There are now 7751 paying members and families, and this I was assured may be taken to represent more than 20,000 persons who are entitled to receive medical aid from the Royal Victoria Dispensary. The income for the year 1894 was, for readmission fees, fines, and cards, £384 7*s*. 9*d*. The subscriptions of the free members amounted to £3184 16*s*. 4*d*., and the midwifery fees to £152 2*s*. 6*d*. Altogether the total payments made by free members amounted to £3596 10*s*. Out of this sum, £2682 14*s*. 3*d*. was paid to the five medical officers who are now attached to the dispensary. What remained was for the most part devoted to defraying the working expenses, purchasing drugs, &c. I have heard no complaint that profit is made out of the medical men.

The friends of the institution argue that it has rendered a great service to the medical profession, as otherwise the profession would never have received the £2682 which the institution has collected and paid over to its medical officers. The medical men who are opposed to the institution urge that a portion of this money is obtained from persons who can well afford to pay proper fees, and that a class of privileged medical men have been created who receive large incomes in exchange for no service, inasmuch as they pay a much smaller sum than they receive to their assistants, who do all, or nearly all, the work. Is it right that more than £1000 a year should be paid to a prominent medical man who does not do the work but devotes himself to a lucrative and extensive private practice, consigning the club patients to his two assistants? These assistants, though duly qualified, certainly do not cost their employer anything like the sum he received from the Royal Victoria Dispensary. I would haste to add that the medical officer in question enjoys the highest reputation, is excessively popular throughout the town, and that not a word has been uttered against him. But a principle of club management is at stake which it should be possible to discuss without casting the slightest reflection on the high honour and unimpeachable reputation of an individual or individuals concerned. The question is simply whether it would not be better to divide the £1000 or more paid annually to one single medical officer, who cannot, and does not, see the patients, among four or five junior practitioners, to whom it would be a Godsend, and who have all the time necessary to devote themselves personally to the patients. Then, again, could not the members of the institution protest that they pay too much? The experience of Northampton shows that it is possible for one single medical officer to derive from these subscriptions more than £1000 a year and get the work done by two assistants for less than £500 a year, thus pocketing, as middleman, at least 50 per cent. of the sum paid by the subscribers. In the face of these figures, which are available to all, why should not the members of the dispensary propose to reduce their subscriptions by one-half, and offer £250 a year to each of the two assistants who are really doing all the work? Several medical men at Northampton were strongly of opinion that it was not right for medical officers to receive large incomes from what was partly a charity and then farm out the work to assistants. The charitable donations, it is true, have singularly fallen off. They only amounted to £91 last year, but they have been much more considerable in times past, and the dispensary itself was started with the £1000 collected as charity money. It is not generally supposed that large incomes are to be made out of such benevolent institutions; and it can be urged that the benevolence of such institutions would be twofold if they not only provided medical aid to the poor, but also a better opportunity for young and rising practitioners to gain experience and the means of existence.

There next comes the wage limit question. In this respect the Royal Victoria Dispensary is head and shoulders above the friendly societies and the medical aid commercial companies, because its authorities do most emphatically recognise the necessity of a wage limit. The rule says that members shall consist of "working persons" who are "unable to pay for medical advice in the usual manner"; and that those who wish to become members "shall leave particulars as to his or her name, age, residence, and occupation at the dispensary." Mr. Charles Becke, who is now acting in his father's stead as honorary secretary, informed me that the committee of management meet every Friday evening and are open to receive any complaints, and would investigate at once any case where a person was receiving medical aid when he could afford to pay the usual fees. They were happy to receive information on such points from any source. When such persons were discovered they were made to leave the institution as recipients of medical relief,

Digitized by Google

but were asked to subscribe as donors and patrons. The committee also visited candidates to see that they were not too well off to become members; but the best proof of their sincerity in this matter could be found in their refusal to amalgamate with the friendly societies. Some years ago, before the friendly societies and benefit clubs federated together so as to establish the dispensary of their own now located in Sheep-street, they proposed that the Royal Victoria Dispensary should take the matter in hand. This was a brilliant offer, for it would have brought in many thousand members. Nevertheless, it was refused because, on inquiry, it was proved that many of the members of the friendly societies were not artisans and working men. It is, as already shown, against the rules of the Royal Victoria Dispensary to admit middle-class persons. Yet in the early history of this institution the difficulty of drawing a hard-and-fast line was keenly felt, consequently the following by-law was adopted: "That it is the opinion of this committee that all artisans and labourers, working as journeymen, should be considered as proper persons to be admitted without reference to the rate of wages which they may be receiving; and that the circumstance of the wives of any of them keeping a shop (excepting beer-shops or public-houses) shall not operate as a disqualification, but that no person filling the situation of a foreman or earning his living solely by keeping a shop should be admitted, it being also understood that no widow or single woman keeping a shop shall be considered as included in the disqualification." Mr. Becke recognises that objections can be made to this rule. Many artisans earn quite enough to pay for medical advice, but it is difficult to minutely examine the condition of a family, and a man with high wages but a sickly wife or relatives to support may be very hard pressed. The matter must be left to the discretion of the committee and for the medical officers to report if they find anyone in good circumstances claiming medical aid. Taken altogether, these rules show that there is the desire to prevent abuses, but has the effort been successful? The medical officers of the Royal Victoria Dispensary on whom I called recognised that there might be some abuses; but, if so, they were in any case contrary to the rules. They also pleaded there were abuses in all institutions, and one of the medical officers pointed to a drawer which he declared was full of the documentary evidence he had accumulated setting forth the abuses prevalent at hospitals. These medical officers were also under the impression that, whatever fault might be found with the Royal Victoria Dispensary, there were far greater abuses at the dispensary set up by the friendly societies. One medical man thought that not only were persons possessing good incomes receiving medical aid from the friendly societies, but sometimes the medical man was cheated by patients turning up for whom he had never been paid. This occurred to him at least three times in the course of a year when he was a club officer. On taking the patient's card and comparing it with the list given him by the club or friendly society, he would find that the patient was not on his list. The patient had paid his subscription, but the medical officer had not been credited with the amount.

On visiting several practitioners who were not connected with the Royal Victoria Dispensary, I found that their view of this institution was far less favourable. After denouncing the Royal Victoria Dispensary as a monopoly worked by assistants, they pertinently inquired why, if the wage limit was so strictly applied, so few persons were refused admittance during the course of the year. When I remarked that, in any case, there were abuses with regard to the wage limit at the dispensary of the friendly societies, a practitioner with whom I was speaking replied that he more frequently came across abuse of the Royal Victoria Dispensary. The latter had an altogether higher class of patients; the friendly societies came next; and the lowest class of all were those recruited by speculating financial companies who threw in medical aid as a bait for securing life insurances. From the window of his surgery, overlooking the villadom of Northampton, he pointed out a row of pleasant houses in which he declared many members of the Royal Victoria Dispensary lived. Personally, he was acquainted with a member of this dispensary who was a greengrocer who had retired from business, and who, when not satisfied with the advice obtained from the dispensary's medical officer, very freely gave guinea fees to a consulting physician. He knew also a fishmonger and poulterer who belonged to the dispensary, and he attended an inebriate tradesman who had not been compelled to resign his membership. This man did not like to call the medical officer of the dispensary when he was suffering from the consequences of his insobriety, and then readily gave a 3*s.* 6*d.* fee, to say nothing of the money he squandered in drink. Yet, in spite of the rule that tradesmen are not eligible, and in spite of the wage limit, this man was kept on the books of the Royal Victoria Dispensary. He considered that the dispensary greatly injured the prospects of private practitioners, not merely by failing to apply their own rules and wage limit, but by their readiness to attend from beginning to end any case of illness for 6*s.* 2*d.* The rule is that, if a person is ill and wants to join the dispensary, he must pay 1*s.* for a month's subscription, 2*d.* for his card, and a 5*s.* entrance fee—total, 6*s.* 2*d.* Thus even the improvident, who have not joined the dispensary when in good health, can for this comparatively small sum avoid calling in a private practitioner. This constitutes a terrible competition. People of restricted means, who call in a medical man, invariably find some neighbour who reproaches them for needless expenditure, since, they urge, all that was necessary could have been obtained from the dispensary for 6*s.* 2*d.*

Such are the main arguments brought forward on both sides by the friends and foes of this great institution. I have only one fact to add. According to the printed report 73,811 consultations were given during the year 1894. As the payment of the five medical officers who, with their assistants, did this work amounted to £2682 14*s.* 3*d.*, this gives an average of over 8*d.* per consultation. I have not yet met with another similar institution which paid its medical officers anything like so high an average per patient seen.

Northampton, December, 1895.

(To be continued.)

ACTION OF THE NORFOLK AND NORWICH MEDICO-CHIRURGICAL ASSOCIATION.

Everywhere we note a determined intent on the part of medical men to withstand the encroachments of the clubs and to promote social and professional intercourse as much as improve pecuniary status by combining for purposes of general protection and co-operation. We welcome these manifestations, for in many cases—of which our articles under the heading of "The Battle of the Clubs" have detailed several—the remedy for existent evil is in the hands of the local profession, if they will seek it in mutual goodwill and apply it with solid firmness.

The position of medical men holding appointments under certain societies has been under the consideration of the Norfolk and Norwich Medico-Chirurgical Society, a body of 120 gentlemen, and the members present at the last monthly meeting, which was held on Dec. 3rd, were unanimous in their opinion that some step should be taken to discourage the canvassing and touting for patients by agents representing clubs, and a resolution to this effect was passed. As an outcome of this resolution the following circular letter was issued by Dr. Thomas J. Compton, the hon. sec. of the society, to the members in his official capacity:

"Heigham Hall, Norwich, Dec. 4th, 1895.

"Dear Sir,—At a fully attended meeting of the society, held at the Norfolk and Norwich Hospital on Dec. 3rd, the report of the Council in reply to Mr. Belding's question: 'Are the medical officers of the Liverpool Victoria Friendly Society included in the strictures passed by the Norfolk and Norwich Medico-Chirurgical Society on medical men holding medical aid appointments?' was received and adopted, and the members were unanimously of opinion that the Liverpool Victoria Legal Friendly Society comes within the meaning of Law VI. 'as unbecoming and unprofessional for any member of the profession to lend his name or to associate himself in any way with such a society'; and it was resolved that the decision of the members should be made known, at an early date, to each member of the society by circular. Law VI. reads as follows:—

> VI.—Any registered medical practitioner who shall be adjudged guilty of and persist in unprofessional conduct, as defined by the code of rules adopted by this society, shall be ineligible to be a member of this society.

"The rules adopted by the society are those formulated by Dr. Styrap, with clause appended with regard to Medical Aid Associations, defined as associations formed as trade speculations, carried on by lay proprietors for the purposes of deriving pecuniary profits from the earnings of members of the profession, and pushed by means of advertisement; or by the employment of paid canvassers who tout and solicit the patients of other practitioners; and that it be deemed unbecoming and unprofessional for any member of the profession to lend his name or to associate himself in any way with such societies or clubs.

"Yours faithfully,

"THOMAS J. COMPTON, Hon. Sec."

Rule VI., which is quoted in the circular letter, has been recently passed as one of the laws of the society in the hope that the medical officers of the associations therein described

Digitized by Google

may recognise the possible ill that may accrue to the profession by lending their assistance to such institutions; and already we understand that several members have signified their intention of relinquishing all connexion with clubs which derive pecuniary profits from the earnings of the profession. The members of the Norfolk and Norwich Medico-Chirurgical Society, in taking this action, fully recognise the necessity of medical aid being essily procurable for those who are unable to pay the usual medical fees, and it is their intention to organise at once a scheme under which this object can be attained, while the medical men remain their own masters. It only remains for us to express our warm appreciation of the action of the society, and our conviction that its results must be satisfactory. Success is assured from the first if the local medical men stand by each other in their intent to help the poor.

We have also received from the Medico-Ethical Association of Fermanagh a copy of their new rules and code of ethics. Upon these we shall comment next week, space to-day only permitting us to congratulate those instrumental in welding together the practitioners of the neighbourhood in the manner indicated by the formation of the association.

THE ASHANTI EXPEDITION.

(FROM OUR SPECIAL WAR CORRESPONDENT.)

I AM sure you will be much interested to learn that we have travelled so far safely, and, what is more satisfactory, that the contingent and all on board our ship are quite well.

On leaving Liverpool we had a strong north-north-west wind, very cold at times, and experienced a nasty rough sea till we were off Ushant. The wind, however, decreased, and sea moderated considerably after leaving this point. Three days after quitting England we enjoyed the luxury of a calm day, which was seized upon as an opportunity to clear up and shake down a bit after the severe dressing we had received; but the brief respite was soon followed by a strong southerly headwind, which, by driving up a nasty, topping cross sea, caused serious discomfort to all on or below decks. Much to the relief of all, the weather toned down on Nov. 29th and proved a great comfort to the sea-sick folk, so much so as to permit even the greatest sufferers from *mal de mer* reappearing in their seats at the dining table. The colonel commanding has now decided to disembark the expedition at Cape Coast Castle instead of Accra, in consequence of the surf being very bad at the latter place. I would also say that, so far as I can ascertain by report, verified by personal inspection, the food served out to the men so far is satisfactory, ample in quantity as well as excellent in quality. The water is much discoloured by iron oxide, in consequence of the bad shakings the iron receptacles have received during the rough weather, and was looked upon by Tommy Atkins as something very bad and likely to produce fever; but after obtaining advice and being satisfied that the fluid was quite pure enough for drinking purposes the soldiers have taken kindly to their allowance ever since.

The day's runs were as follows: Nov. 24th, 244 miles; Nov. 26th, 235 miles; Nov. 27th, 175 miles; Nov. 28th, 198 miles; Nov. 29th, 248 miles; Nov. 30th, 244 miles.

SS. *Bathurst*, at sea, nearing Grand Canary,
Nov. 30th, 1895.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Recent Assizes.

MR. JUSTICE COLLINS concluded, on the 5th inst., an assize which will be memorable for the number and gravity of the cases tried. Four prisoners are now in H.M. Prison, Walton, under sentence of death, the juries having convicted each of wilful murder. In addition to these, two other prisoners were sentenced to fourteen and twelve years' penal servitude respectively for manslaughter. In the former case the grand jury ignored the bill for murder, but found a true one for manslaughter. The prisoner pleaded guilty; he was a labourer who had killed his wife under very aggravated circumstances, Mr. Justice Collins observing that it was the worst case of its kind he had ever tried. Both parties were given to intemperance, but the prisoner repeated his violence again and again after intervals, until the poor woman sank exhausted. In the other case, the prisoner O'Callaghan was an unqualified assistant to the surgeon whose son he murdered under shocking circumstances. As is too often the case, the local press made it appear that the prisoner was a fully qualified medical practitioner, which is not true. Much to the surprise of many who heard the trial the jury found a verdict of "Manslaughter," but the judge showed his sense of the enormity of the crime by the sentence he pronounced.

The Criminal Law Amendment Act and Early Pregnancy.

There were a large number of cases of felony and misdemeanour under the Criminal Law Amendment Act, 1885. In one case where the prisoner was charged with misdemeanour the girl, who was only fourteen years and five months old, was delivered of a fully matured child on Nov. 2nd last, and in another case the girl, though only fifteen, was several months pregnant. It is significant of the effect of new Acts of Parliament in creating new offences that prior to the Act of 1885 neither of these cases would have been a criminal offence; while before the year 1875 what may be termed the "felony age" was under ten, and the misdemeanour age above ten and under sixteen. As it is well known that the majority of females do not attain puberty till the age of fifteen, the provisions of the more recent Act have reasonable grounds for their enactment. There is much to be said in favour of extending the age from sixteen to eighteen.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary: Election of Pathologist.

DR. T. BEATTIE has been elected pathologist at the Royal Infirmary. He is an excellent man for the post. Formerly the members of the honorary staff were appointed by the governors and canvassing was allowed; but as this involved considerable expense, and was troublesome to both the candidates and the electors, the system was altered. Now the honorary staff are elected by the house committee, the consulting staff, and, in addition, by a selection committee consisting of thirty governors who are not otherwise connected with the management of the institution, and canvassing is forbidden. The house committee consists of thirty-two members, and there is at the present time a consulting physician and a consulting surgeon, making the constituency sixty-four. Of these sixty-four votes only thirty-eight were recorded last week. It may be taken that on every election the house committee, of which the eight members of the staff are members, will vote, so that practically the house committee has in its hands the election of the honorary staff. Many will say this is as it should be, for the house committee knows most about the requirements of the institution and takes the greatest interest in its management. There are, however, two sides to the question, and when thirty outside governors were appointed to take part in the election of the honorary staff it was certainly never contemplated that, as on this occasion, less than half of them would record their votes. If canvassing is not to be allowed it is obvious that, under the present system, candidates who have had no connexion with the infirmary, opposed by those who have, are still further severely handicapped. Other hospitals have changed their method of electing the honorary staff in the direction the Newcastle Royal Infirmary has, and it would be interesting to know whether they are satisfied with the result. The method of the election of the honorary staff is certainly a very important matter to a hospital and to the public.

Newcastle-on-Tyne, Dec. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Lord Rector's Address at Edinburgh University.

LORD JUSTICE GENERAL ROBERTSON, Lord Rector of Edinburgh University, delivered his rectorial address in the Synod Hall on Friday of last week. The hall was crowded

Digitized by Google

by students and others, and the chair was occupied by the principal, Sir William Muir. The Lord Rector began by thanking the students for the honour they had done him by electing him, and reminded them that he was the first Lord Rector who had been elected by the votes of female as well as male students. The traditions of the University were Scottish, and some of them even local; but while still retaining its patriotism it had become in the highest degree cosmopolitan. A moiety of the students are drawn from England, Ireland, Australasia, Canada, and India, while no local partiality has prevented the chairs being filled by the best of the distinguished men of all seats of learning who have desired them. This showed that the true ambition of Scotland was not to be satisfied with a commerce of the mind limited to their own land. The body of undergraduates constitutes a living appeal to the imperial sentiment of the community in which they live. If with sober pride they may believe that the training of the University attracts men from afar, let it not be forgotten that prestige must not be slept on. The credit of all colleges incessantly fluctuates, and is only maintained by achievement and prowess. He referred to a movement on foot for encouraging research by enabling picked men who had shown scientific insight to stay awhile in the University and prosecute investigations. Looking to the prosperity of the University, they need not merely the very best machinery for acquiring the very best skill in all the professions, but here, as everywhere, it is the forward policy, the shining feat, that captivates mankind. And he hoped that some wealthy Scotsman would link his name in imperishable honour with the scientific future of their country by endowing research. Referring to the fact that that was probably the last time an important university function would be held in a hired hall, he took for his next words the words on the roof of the McEwan Hall: "Wisdom is the principal thing; therefore get wisdom: and with all thy getting get understanding." Other good gifts the University had to bestow, but this was the gift of her right hand. It was not professional skill, or scientific knowledge, or literary accomplishment, although all were instruments towards this attainment: it was the balanced mind, the candid disposition, the educated view that perceives the relations of things, that is alive to analogies and not innocent of irony, that does not expect to find all things in categories, and all black or white, that is reverent to what is great and disaffected to what is smug. Not in mental acquisition, but in mental habit is wisdom found. The University is also the nursing mother of culture, and her sons its champions. In its pristine meaning culture included appreciation of form and love of the beautiful, but the crown and flower of all education was intellectual magnanimity. Hence in the choice of studies wise men, if their leisure be small, will go to the main streams of thought and action. However interesting may be the by-ways of history, the curiosities of literature, and the eccentricities of criticism, it is not there that magnanimity will be learned. He then proceeded to speak of the public value and public duties of disciplined intellect. If he had at all sketched the qualities of the educated mind, its capacities for the comprehension and furtherance of national interests stood apparent. In proportion as the mind of a country is driven away or withdrawn from interesting itself in the State and serving the State, that country is weakened and human progress is stunted. In urging the duty of educated men, he spoke not only of active participation in politics, for more direct and subtle agencies were at least as potent. What was required was that the light of knowledge should be turned on the path of this self-governing people and the best aid given by the best minds. Every man's life had its patriotic side, and his responsibility is not lightened, but increased, by the degree of his mental equipment. There is due to the State a tribute or excise out of cultivated intellect, and at present he doubted if the State got its due. He spoke thus because he had an immense desire for the success of the system of popular government now established among them. That success must depend on the prevalence of reason in its counsels, and he did not believe that British householders were hostile to reason or disinclined to avail themselves of the best informed guides. He considered the pessimist view, which was that the many were ignorant, poor, and selfish, and would overbear the men of light. He thought all that highly fallacious, and argued against it, showing if it would ever be so it was because the men of reason and intellect had accepted the game as up. It was one of the reassuring signs of the times that plain speaking and courage were increasingly popular. He used the term pessimist to describe the desponding and disaffected tone about popular government which is not unknown in university circles, and which unquestionably tends to deprive the State of what is its due. He suggested that it was the duty of men of culture to take more part than they do in current affairs. They ought to take their proper place, but they will only get it if they realise the condition—the very natural and quite tolerable condition—of popular government, and more or less of all governments: "If thou wilt be a servant unto this people this day, and will serve them, and answer them, and speak good words to them, then they will be thy servants for ever." He next dwelt upon the necessity of a better, improved, more liberal, and more steady public opinion; and said that questions which were sure to come up in the future should be faced so that events should be moulded and developed beforehand. He referred particularly to the subject of Socialism. It would be said that the performance of what he described as the part of educated men in the State depended on a high standard of public spirit, and he assented to it. Why should there not be such a standard? And if to the attainment of it some further effort be required, where better and to whom could an appeal for such effort be made than here and to them? He had a right to address them, undergraduates of a great university, as children of the light and children of the day. As the personal possession of culture was the condition on which alone the service of which he spoke could be rendered to the State, he did not wish to divert their attention from the studies to which they were at present pledged, but rather to suggest another and a nobler reason for their strenuous prosecution. Whatever their future might be, they must not lose sight of the State or regard the ambiguous problems of political progress as outside the ambit of their influence. There was not an intellectual life well led, not a book well written, not a discovery made, that might not by some conscious regard to general enlightenment be invested with a double beneficence. The address was listened to with close attention.

Extension of the Edinburgh Royal Infirmary.

The managers of the Edinburgh Royal Infirmary have finally decided to recommend that the proposed extension of the infirmary should be at once proceeded with. The complete scheme of extension is estimated to cost £100,000, but it is proposed at present only to go on with half that amount. The new buildings will occupy the site of the old Sick Children's Hospital and the land to the north of it to the east of Lauriston-lane. The extension is much needed, for during the greater part of the year there is a much greater demand for beds than can be supplied.

The President of the Royal College of Physicians of Edinburgh.

Dr. J. Batty Tuke has been elected to the Presidential chair in succession to Professor Gairdner. Professor Simpson has been renominated Vice-President.

The Edinburgh Medico-Chirurgical Society.

This society met last week. Dr. Craufurd Dunlop read a valuable paper on investigations he had made on the presence of Oxalic Acid in Urine; and Dr. G. A. Gibson read a record of a series of interesting cerebral cases which had been operated upon with variable success.[1]

Outbreak of Typhoid Fever at Dunbar.

A considerable outbreak of typhoid fever has occurred in Dunbar, and is causing interest because of a difference of opinion as to its probable cause. This is one of the districts in which caravan hospitals are being tried, as was mentioned in THE LANCET at the time.[2] One of these was being used for cases of typhoid fever and, according to one statement, was so placed that a cesspool for its use drained into a small stream, the water of which entered directly or indirectly into the water reservoir for the town. The other statement is that the water of a loch in connexion with the water-supply was bad, evidence of this being found in the fact that many dead fish have been discovered in it. The expert opinion seems to be at variance and appears to have got mixed up with the question of the suitability of caravan hospitals. The

[1] A report of the proceedings will be found on another page.—Ed. L.
[2] THE LANCET, May 25th, 1895.

Digitized by Google

site upon which a caravan hospital is placed is necessarily one of great importance, but an error in this particular should hardly be allowed to discredit a scheme that is at least deserving of a fair trial.

Dec. 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mater Misericordiæ Hospital.

THE interesting case of intestinal stricture in which Mr. Coppinger a month ago established a lateral anastomosis between the ileum and transverse colon has progressed favourably. As will be remembered from the brief notice of this operation which appeared in THE LANCET of Nov. 23rd, a Murphy button of aluminium, imported from Chicago by Messrs. Fannin and Co. of this city, was made use of. Now, it has recently been discovered that aluminium is soluble in alkaline saline solutions, a fact which is said to have taken the French naval engineers recently by surprise, and to have caused the destruction of some of their modern torpedo-boats. The metal seems very stable, and is certainly no more prone to oxidise or tarnish under ordinary conditions than gold or silver, but it dissolves with effervescence in even a dilute solution of potash. Under these circumstances, and in the absence of any reports dealing with the matter in the medical journals, the behaviour of the button in this case was noted with considerable interest. It only appeared on the eighteenth day after operation, and seemed little the worse for its long sojourn in the intestine or for the work which it had successfully performed. Its two parts, however, were found to be adherent, as if soldered together, and although steeping in ether, boiling in oil, &c., were tried, it was found impossible to unscrew the instrument or to separate its halves. I would suggest that the next surgeon who places an aluminium anastomosis button in a patient's lower intestine should have it carefully weighed before and after use, and that he be prepared for any effect that the absorption of the alkaline salts of that metal might possibly produce.

City of Dublin Hospital.

Ligature of the second portion of the left subclavian artery was successfully performed by Mr. Henry G. Croly at this hospital on the 3rd inst. The patient suffered from a traumatic aneurysm which overlay the third part of the artery and rendered operation impossible in that situation. Some of the outer fibres of the anterior scalenus muscle were accordingly divided, and a ligature of kangaroo tendon applied round the bloodvessel in its second portion. The patient is doing well on this the eighth day after operation.

Dublin University Biological Association.

At the opening meeting of this association, which was held on the 5th inst. in the New Building, Trinity College, Dr. Alfred R. Parsons, the incoming President, read a very interesting paper on Modern Tendencies in the Treatment of Disease. It was listened to by a large and appreciative audience, which included the Presidents of the Royal Colleges of Physicians and Surgeons, and the President of the Royal Academy of Medicine, Ireland. The latter—Dr. James Little—contributed an able speech to the discussion which followed, while Professor Purser, Sir C. Nixon, and Dr. C. E. Fitzgerald proposed or seconded resolutions.

The House of Industry Government Hospitals.

Mr. James Wilson Hughes, who was well known and esteemed in medical circles in Dublin, died on the 9th inst. The deceased gentleman filled the offices of secretary for more than thirty years to the Richmond, Whitworth, and Hardwicke Hospitals, as well as to the Westmorland Lock Hospital and St. Mark's Ophthalmic Hospital.

Epileptic Patients in the Belfast Workhouse.

The Local Government Board have sent a communication to the Belfast board of guardians pointing out that, while they consider it proper that epileptics should be classified in a separate ward where they can receive the special attention necessary to their condition, they think it undesirable that such a ward should form part of the lunatic department. Simple epileptics—that is, epileptics whose mental condition in the intervals between their seizures is sound—should not be associated with the insane who happen also to suffer from epilepsy. The Local Government Board hope that the guardians will separate the epileptic ward intended for simple epileptics from the lunatic department of the workhouse. A sub-committee of the guardians have also been considering this question, and on the same day as the letter from the Local Government Board was made public this sub-committee in their report to the board of guardians recommended that a cottage hospital should be provided for the accommodation of the epileptics on a piece of ground adjacent to the lunatic department, where at any time they could have the advantage of the advice of the resident medical officer.

Sanitary Powers for Portrush.

At a meeting of the Portrush town commissioners, held on Dec. 4th, a resolution was carried to the effect that a petition be presented to the Local Government Board to have the town of Portrush constituted an urban sanitary authority. Portrush is the leading summer health resort in the North of Ireland, and at present the two main factors of a town from a health point of view—the water-supply and the sanitary arrangements—are not controlled by the town commissioners. These matters are managed by the Coleraine board of guardians, many of whom reside a long distance from Coleraine, and it is naturally felt by the town commissioners who live in Portrush that people residing there would take a much greater interest in the condition of the place, hence they are anxious that an urban sanitary authority should take charge of the town. There is all the more necessity for this being done at once, as during the past summer there was a strong feeling existing among those who resided at Portrush that both the water-supply and the sanitary arrangements of the place might be improved.

Certificates in Lunacy Cases.

At the weekly meeting of the Lisburn board of guardians, held on Dec. 3rd, the chairman read a letter from Mr. Jefferson (dispensary medical officer), in which he said that in a certain lunacy case (named) he filled in the usual form certifying that the person was a dangerous lunatic, and also a copy to be forwarded to the Lunacy Commissioners in Dublin. When the resident magistrate at Lisburn read it he ordered Mr. Jefferson to be sworn. The latter declined, as he said his certificate was sufficient, and added that he would take the oath with pleasure if the magistrate would show him the law compelling him to be sworn. This the resident magistrate declined to do, and Mr. Jefferson left the court. The chairman also read a letter from the Local Government Board stating that Section 10 of 30 and 31 Vic., cap. 118, only requires a medical officer to certify a person to be a dangerous lunatic. There is nothing in the section as to his giving sworn evidence, and the guardians would do well to consult their solicitor in the matter. Mr. Jefferson deserves the thanks of the profession for the manly and dignified stand he took in this matter.

The Rate of Speed for Ambulances.

The city coroner of Belfast and the police committee are at present at variance on the question of the speed at which the ambulance carriages should be driven. Formerly these most useful vehicles were allowed to go at a quick rate if summoned to a street accident, but of late they are only allowed to go at a trot. A jury at an inquest some time ago condemned this slow rate of progression, but, notwithstanding, at an inquest held on Dec. 6th a member of the fire brigade (who take charge of the ambulances) said that they could only trot, as the coroner put it, "to save human life," while to save property they are allowed to gallop. The coroner having expressed himself strongly on this matter at the inquest on Dec. 6th in reference to the death of a man who was rescued from the water at the quay, and who was subsequently taken by the ambulance to the Royal Hospital, the jury added a rider to their verdict in which "they strongly protested against the action of the police committee of the corporation in preventing the ambulance from proceeding at a rapid pace on its work of mercy to save human life, while it permitted the fire brigade to gallop to save property."

Charge of Infanticide: the Frenzy of Parturition.

A case tried at the Cork Assizes last Saturday is of considerable importance from a medico-legal point of view. A domestic servant, only seventeen years old was charged with the murder of her child. In a small loft over the room in which the prisoner had slept the body of the child was found The head had been cut off and the arms were tied together

Digitized by Google

with handkerchiefs and clothes belonging to the accusedr Mr. Falvey of Tralee, probably alluding to the smallness. of the pelvis, stated in evidence that the circumstances under which the birth occurred must have caused the girl frightful suffering, and he believed that owing to her great suffering she would become unconscious of what she was doing. Mr. Denny of Tralee gave similar evidence, and the judge in summing up said that, if the jury thought that the prisoner from the condition of her mind was not guilty of the murder, he took the responsibility of directing them that they could come to the conclusion that she was guilty of the offence of concealing the birth of the child. The jury after half an hour's deliberation found the accused had committed the act charged against her, but that she was insane, so as not to be responsible, according to law, for her actions at the time that the act was done. His lordship then ordered the prisoner to be detained as a criminal lunatic until her Majesty's pleasure with regard to her should be made known.

The Proposed Amalgamation of the Mill-street and Kanturk Unions: Important Government Project.

The guardians of the Millstreet Union have been for some time desirous of amalgamating their union with the Kanturk Union and of converting the Millstreet workhouse into an auxiliary lunatic asylum. The Local Government Board sent one of their inspectors to hold an inquiry on the subject, and they have informed the Millstreet guardians that they do not at present feel at liberty to sanction the proposed amalgamation, as the Kanturk guardians are entirely opposed to it. In the course of their letter the Local Government Board made the very important statement that "the Government have under consideration the propriety of adopting a general scheme of amalgamation in connexion with a better system of the classification of the poor in workhouses." The proposals of the Government are anxiously awaited, as a rearrangement such as is suggested would be likely to result in an amelioration of the lot of many of the poor people who are obliged to seek the shelter of the workhouses, and the taxpayers would hope for a considerable retrenchment of establishment charges.

The Belfast Nurses' Home and Training School.

At the annual meeting of this medical institution, held on Nov. 29th, it was reported that the year 1895 was its most auspicious one as regards its most vital interests as a training home—viz., its connexion with the Royal Hospital. The board of management of the Royal Hospital early in the year agreed to furnish a room in the hospital for the lady superintendent of the Nurses' Home, and, subject to their existing rules, to give her the complete control of the nursing of the hospital and the general cleanliness of the wards. Further, the Royal Hospital board arranged that the ladies of the Nurses' Home committee should in turn act as orderlies in the hospital, invested with their authority to visit not only the wards but the hospital generally, and to report directly to them on any subject they should consider necessary or desirable. In a very able speech, made by Professor Cuming in moving the adoption of the report, he said the arrangement made between the Nurses' Home and the Royal Hospital had his entire concurrence. As he pointed out, the interests of the two places (the Royal Hospital and the Nurses' Home) were concurrent, and everything that tended to improve the one tended also to improve the other. Professor Cuming spoke in very feeling terms of the great loss sustained by the hospital and the Nurses' Home in the death of Dr. Ross, a man who had left an example to his colleagues that it would always be well to profit by—the example of a man who was strictly devoted to his duty and who was unfailing in his regard for every form of misery and distress.

Dec. 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Budget of the Paris Hospitals.

IT may interest the friends of such institutions as my own dear old Guy's Hospital, which, owing to depreciation in the value of agricultural property, have to struggle against bad times, to be placed *au courant* of the sum asked for annually by the Assistance Publique for the maintenance of the hospitals of Paris. For the coming year the total expense is fixed at the enormous sum of 49,275,296 fr. 50 centimes, or nearly £2,000,000. The total number of days spent in hospital in 26,307 beds by patients during 1895 was 9,068,000, these beds including those found in hospitals properly so called, infirmaries, *maisons de retraites*, and divers foundations. The hospitals strictly so denominated represent 12,750 beds, with 4,517,000 days spent therein by patients. The salaries of the administrative *personnel* (*chef* and *employés de bureaux*, *directeurs des hôpitaux*, &c.) attain, together with sundry accessory expenses, the total of 2,196,310 fr. The medical *personnel* absorb 768,400 fr., thus apportioned:

132 physicians	198,100	francs.
63 surgeons	80,400	,,
14 accoucheurs	19,100	,,
253 internes (medicine and surgery)	184,100	,,
21 pharmacists	114,000	,,
153 internes en pharmacie	107,600	,,
18 dentists	10,200	,,
38 midwives (*sages-femmes*) ...	42,300	,,

Then come, in addition, the director, demonstrators, and *chefs de laboratoire* of the Anatomical School of Clamart, who collectively receive 12,600 fr. Accessory expenses, comprising 125,000 fr. for indemnity to externs of out-of-the-way hospitals, and 99,000 fr. paid to the newly created *assistants de consultation* (young medical men who replace hospital physicians and surgeons in the out-patient room), reach 335,468 fr. The nursing department costs 1,973,550 fr., this department being made up of 71 nuns, 249 male and female superintendents (heads of wards), 624 sub-superintendents, 354 extra superintendents, 390 first-class male and female nurses (*infirmiers* and *infirmières*), and 2742 ordinary nurses (male and female). The drug department costs 1,370,000 fr., and surgical instruments, apparatuses, and dressings involve an expenditure of 1,154,035 fr. Some idea of the costliness of modern materials for the dressing of wounds may be gathered from the under-mentioned details:

Carded wool	80,000	francs.
Ungreased cotton wool ...	76,000	,,
Ordinary cotton wool and peat	700	,,
Muslin	215,000	,,
Iodoform gauze	57,000	,,
Salol gauze	14,000	,,
Carbolic gauze	3,000	,,
Oiled silk	46,000	,,

The commissariat department absorbs nearly 6,000,000 fr., 1,000,000 fr. going for bread, 3,290,000 fr. for meat, and 1,400,000 fr. for wine.

Is Gastro-intestinal Antisepsis realisable?

We know that since the researches of Bouchard and the late Dujardin-Beaumetz the disinfection by means of drugs of the gastro-intestinal canal has become quite a common therapeutical practice, especially in France. The most common method of attaining this result is to prescribe a mixture (in *cachet*) of salicylate of bismuth and benzo-naphthol or β-naphthol. But is the cleansing result as satisfactory as the authors of this method would have us believe? Dr. Bardet asked this question on the 27th ult. at the Société de Thérapeutique, and adduced some facts that appear to negative the value of the much-vaunted and seductive method. The test of the efficacy of these antiseptics is the deodorisation of the stools, the diminution of their maximum of toxicity, and a like diminution of the degree of urinary toxicity. Now, Dr. Bardet denies that deodorisation means an anti-ferment action. Besides, fœtidity of the fæces is not necessarily indicative of putrid fermentation, which rare event is almost exclusively met with in biliary retention. He maintains that the deodorisation (so called) procurable by the use of intestinal antiseptics is in reality only a masking of the odour, this being proved by their powerlessness to attenuate the fœtor of really putrid fæcal matter, and because such deodorisation cannot be obtained by the employment of even powerful (non-aromatic) antiseptics such as mercurial salts. The bacteriological experiments of Dr. Bardet lead him to believe that the diminution of micro-organisms in the fæces brought about by the administration of naphthol, &c., is not real, and that Baczkiewicz is mistaken on this point. The culture on plates of previously diluted fæcal matter passed by four individuals before and after the prolonged administration of a daily dose of four grammes of benzo-naphthol yielded invariably an equal number of colonies. The change in urine toxicity is, according to Dr. Bardet, not a fair test, that being dependent on other concomitant agencies. He concludes, then, that local or general antisepsis of the alimentary canal by

Digitized by Google

means of salol, naphthol, or benzo-naphthol is an impossibility. He adds that their decomposition in the intestines is far from being a constant occurrence, for they frequently accumulate or are voided unchanged. Dr. Bardet does not, however, deny that favourable results are sometimes yielded by the method, but he is certain that the usual explanation of this action is not the true one.

The Sanitary Condition of the French Army in Madagascar.

The *Médecine Moderne* states that according to a letter addressed from Madagascar on Oct. 10th, to the *Tablettes des Deux Charentes*, the sanitary condition of the expeditionary force for the entire campaign was at that date as follows: deaths, 4000; in hospital, 6000; unfit for service (éclopés—lame), 3000. This left 2000 men fit for service out of a total of 15,000. But is there not some exaggeration in these figures?

Dec. 10th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Army Medical School.

THE centenary of the Army Medical School (Friedrich Wilhelms-Institut) was celebrated with great display on Dec. 2nd. A case of small-pox having occurred on the premises, it was considered inadvisable to conduct the ceremonial proceedings there, and they accordingly took place in the great hall of the University, where the leading army and naval surgeons and many old pupils assembled from every part of the empire. Prince Frederick Leopold, represented the Emperor, and delegates of the Government, the University, and the army were also present. The opening speech was delivered by General-Staff-Surgeon Dr. von Coler, the chief medical officer of the army, who pointed out that the kings of Prussia, and at a later period the emperors of Germany, always attached much importance to a well-trained army medical staff, and he then gave a short historical account of the medical service of the army. The results of recent improvements in practical surgery had been conspicuously shown during the last wars, but the development of practical hygiene was not less important. By improving the hygienic conditions of the army the amount of invaliding had been reduced by 42 per cent. since 1868, and the mortality by not less than 57 per cent. The lives of 2000 soldiers had, in fact, been saved by hygienic measures; for the deaths in 1894 were 2000 fewer than they must have been if the rate of mortality had been the same as in 1868. Following Dr. von Coler the Minister of Public Instruction congratulated the Army Medical Staff, saying that medical science in general was much indebted to them, since men like Professor Virchow, the late Professor Helmholtz, and others had been pupils of the Army Medical School and had begun life as army surgeons. The Rector of the University and the Dean of the Medical Faculty then spoke on behalf of their respective corporations. Finally, the Minister of War, General Brousart, read an imperial order, by which the Army Medical School was henceforth to be called the Emperor William Army Medical Academy. A reorganisation of it is also contemplated, details of which will, in course of time, be published by the War Office.

The Training of Military Surgeons.

The German method of training military surgeons is quite different from the British system, according to which all candidates for the medical service of the army are already duly qualified practitioners and in possession of a degree or diploma before their special military training is commenced. In Germany, on the other hand, the young men enter the Army Medical School at the beginning of their period of study; they board in the college free of charge, receive an allowance, and are trained in the University at the expense of the War Office. For every year they have been in the college they are obliged to serve two years in the Army Medical Staff. Although these students are under military jurisdiction—and, in fact, are military men—they wear no uniform whatever and possess almost the same academical freedom from restraint as the civilian students, attending together with them the lectures of the professors of the University, fulfilling the same curriculum, and passing the same examinations; they, however, may not choose their lectures or professors at their own discretion, but must attend where they are ordered. Besides the lectures at the University, additional courses are held for them in the college by the army medical officers on duty there, and during the final stage of their study instruction in military surgery and medicine is given by special military teachers. The college has the largest medical library in Germany, containing more than 50,000 volumes, good laboratories, and collections for the exclusive use of the students. After having taken their degrees and qualifications the pupils are appointed as army medical officers. But there are further advantages in store for them; the offices of clerk and dresser in the Charité Hospital are exclusively reserved for the pupils of the Army Medical School, and according to the regulations of this hospital the majority of the assistant physicians and surgeons must be army medical officers. The cause of this singular rule is twofold—namely, that the Army Medical School existed long before the University was founded, and that the Charité Hospital was originally of a purely military character. The great preponderance of the Army Medical Staff in the Charité Hospital and some other medical institutions belonging to the Government has always been regarded with some anxiety by the other members of the profession, and the military medical students are not universally liked by the civilian students, who complain that they are excluded by them from many of the better appointments.

Employment of Army Medical Officers in Civil Hospitals.

Since the above was written the medical profession has again been surprised by an announcement in the lay press relative to the employment of army medical officers. According to the plans of the Government a number of them will henceforth be appointed as assistants in several university and municipal hospitals, not only in Berlin, but also in the provincial towns. They will, as a rule, hold their appointments for six or twelve months, and will then be replaced by a new series. Arrangements have already been made by the Government with the boards and chief medical officers of some hospitals, and a large number of them are said to be very favourable to the innovation. The hospital boards will in this way save the salaries hitherto paid to their civilian assistant medical officers, as, of course, the Government will bear the expense of the new scheme. The army medical authorities, in explanation of their action, declare that the surgical training of the army medical staff is of supreme importance, especially in time of war, and that the military hospitals do not afford sufficient opportunity for surgical practice. This may be perfectly true, but the civilian population also has a just claim to the services of well-trained civilian surgeons. The number of hospital appointments in this country is very small, and only a few medical men are fortunate enough to be selected for them. If a portion of the appointments be reserved for army medical men the interests of the civilian profession will undoubtedly suffer, and it seems highly desirable that the legal advisers of the provincial medical boards (Aerztekammern) should give their views on this question.

Primary Actinomycosis of the Lungs.

Dr. Heusser, of Davos, Switzerland, has recorded in the *Berliner Klinische Wochenschrift* a case of primary actinomycosis of the lungs. In November, 1894, there was sent to him by Professor Lichtheim of Königsberg a lady who had fallen ill in April with all the symptoms of acute pleurisy. She had been in hospital under the care of Professor Lichtheim, and paracentesis was performed, by which 600 c.c. of serous fluid were drawn off, but the fever nevertheless continued. In the expectoration, which was scanty, no tubercle bacilli could be found. The patient was first sent home to the country, where she was expected to recover, and afterwards to Davos. There a slight infiltration of the right upper lobe and a cavity in the right lower lobe were diagnosed. In the expectoration, however, to the surprise of the physician in charge, instead of Koch's bacilli, typical actinomycetes were discovered. Although at first the case seemed to be hopeless the general state of the patient eventually improved. The fever very soon disappeared, the patient's weight increased 7·7 kilos. (= 17 lb.), and the infiltration of the lungs became apparently less. Nevertheless, actinomyces fungi, together with numerous streptococci, were still found at the time of her departure from Davos. It has for a long time been said that the climate of Davos is favourable to the arrest of tuberculosis, and according to Dr. Heusser this case seems to prove that it also tends to check the development of actinomycosis. He hopes that a residence on the mountain may be beneficial in cases of actinomycosis in other parts of the body.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Quinine in Italy.

I HAVE before me the Bill drawn up by Signor Boselli (Finance Minister) for the better regulation of the sale of quinine—a Bill which, if it become law, will prove of no small advantage to the profession, and, through the profession, to the public. In Italy about 16,000 persons annually die of malarial fever; about 3000 communes are unprovided with pharmacies at which prescriptions can be made up; and the average price at which quinine can be obtained by the public is 500 lire (£20) the kilogramme, while the State procures it for the army and navy at only 60 lire (£2 8*s.* 4*d.*) the kilogramme. It is worth remarking, moreover, that where malaria is most prevalent commerce is non-existent and the population is of the poorest—in other words, precisely where the bane falls heaviest the antidote is not to be had. His Excellency Signor Boselli proposes to remedy this condition of things, disclaiming in advance all intention of creating a State monopoly. He would concede to the firm or firms which purvey the drug the simple right to avail themselves of the shops in which are sold and retailed articles of a privileged character (*generi di privativa*)—like salt or tobacco, for instance. These shops are disseminated throughout the kingdom to the number of 27,000, are found in the humblest communes, and, being in direct contact with the public, can make quinine accessible to all. They are subject, moreover, to Government surveillance, which can repress every possible abuse. On payment of a small sum they can acquire the right to sell the privileged article, and Signor Boselli makes it obligatory on them to have on sale either the sulphate or the hydrochlorate of quinine or both—the hydrochlorate being the more energetic, and the sulphate the more commonly in use. The quality will be of the utmost purity, any adulteration being visited with rigorous penalties. The drug, whether sulphate or hydrochlorate, is to be sold in circular tablets, which can be easily swallowed, each tablet to be enclosed in a capsule to ensure perfect preservation. The price will be fixed at a sum which even the very poor can command—a price uniform throughout the kingdom for the sulphate and hydrochlorate respectively, so that three grammes of the sulphate will cost 50 centimes (5*d.*), and two grammes of the hydrochlorate also 50 centimes. There is little doubt that the Bill will become law, and as little doubt that it will prove a mighty boon to the Italian lower orders. Nothing can exceed the confusion and irregularity under which quinine is now sold. At Milan, for instance, it may be had for 25 centimes the gramme; at Florence, on the other hand, the same quantity costs double, sometimes treble, that sum. But even more important than the question of cheapness is that of purity. Every English physician practising in Italy knows to his cost the difficulty of procuring genuine quinine. For years it was sold, even in pharmacies of repute, adulterated with 60 per cent. of cinchonidine. Now there is a prospect of getting a pure and effective article, and the sooner Signor Boselli's Bill passes through committee and is entered on the statute-book the better for the practitioner in Italy and the public under his charge.

The Health of the Pope.

His Holiness is so far re-established in health that on several of the bright, dry, exhilarating days we have been enjoying lately he has been able to take carriage exercise in the Vatican gardens. These outings are timed for midday, when the warmth is greatest, and have included a visit to the Tower of Leo IV. and to that stretch of the gardens which is cultivated under His Holiness's direction.

Dec. 10th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Sanitation in Moscow.

THE following notes relating to the sanitary condition of Moscow, gathered during a brief stay in that beautiful city, may be of interest. The population of Moscow when the last census was taken in 1889 was about three-quarters of a million; it is at present reckoned at something just under a million. The city is rapidly growing, and it is calculated that in a few decades the population will be double what it was at the last census. The exact death-rate of Moscow is not easy to ascertain in the absence of more exact knowledge as to the present population, and it is not stated even approximately in the annual health reports of the city. It appears, however, that the mortality is really something like 35 or 37 per 1000 living. This high death-rate is partly, but not wholly, explained by the large number of deaths among children in the Foundling Hospital. In the last annual report for 1893, of the 27,067 deaths which occurred in the city, 3034 were of infants in the Foundling Hospital. These deaths are generally excluded from the mortality statistics, and with justice, as the large majority of children brought to the hospital are born outside Moscow. They are only kept in the hospital for one month, and are then put out to nurse in various villages; the number of children who annually pass through the hospital varies from 16,000 to 20,000. But even after these deaths are excluded from the general mortality, the death-rate remains at something just under 30 per 1000.

The water-supply of Moscow is at present in a stage of transition. Two years ago a new system of supply was opened; pipes were laid down, and a constant supply to each house afforded in something like one-third of the city. The remaining houses still obtain their water by means of barrels brought round on small hand-carts. The water they receive is, however, the same as that supplied directly to the other houses, the barrels being filled from large underground cisterns, of which there are several in different parts of the town. The water distributed is therefore ultimately from the same source for the whole of Moscow. This source is at a distance of some ten versts (seven miles) from the city boundaries. It consists of Artesian wells, forty in number, covering a considerable area of ground near the village of Muititsch. The soil there is for the most part clay. The water is brought in cast-iron pipes, two feet in diameter, to the Alexéiefski pumping works, about one mile from the city barriers. There is here a small underground reservoir capable of holding 300,000 vedros (a vedro is 2·7 gallons; this is therefore some 810,000 gallons). Thence the water passes to the Krestofski water towers within the city barriers. There are two towers, each 128 feet high. At the top of each is a reservoir of cast iron holding 150,000 vedros. As the daily supply to the city is between one and one and a half million vedros, the water in all these reservoirs is changed several times in the day. The water is distributed to the city from the towers by a pipe twenty-eight inches in diameter. This, as all the other cast-iron pipes, is "processed" inside by one of the tar processes for protecting iron. If the present population of Moscow be a million, the daily water-supply is only about three or four gallons daily per head. To increase this extremely small water-supply is a problem now occupying the municipal authorities. The present source at Muititsch is capable of supplying considerably more than it does at present, and to still further supplement this it is proposed to take water from the Moskva river some distance above the point where it enters the city. It is hoped that in this way it will be possible to supply seven vedros (nineteen gallons) daily to each person. The water from the river is said to prove, on examination, to be of remarkable purity. Like all rivers, however, it has the disadvantage that there are a number of villages along its banks, from which much objectionable matter must inevitably reach the water. The present water-supply is entirely unfiltered; the water, from the chemical and bacteriological points of view, is, nevertheless, of a high degree of purity. Before leaving the subject of the water-supply, it is worth noting that the distributing pipes have to be laid at least ten to twelve feet below the surface on account of the intense cold in winter. In the great frosts of the winter of 1892–93, even at this depth, a large number of pipes were split by the cold. Ninety degrees of frost (−58° F.) occurred on more than one occasion.

Up to the present time there has been no system of drainage in Moscow, the old and objectionable cesspool taking its place. The authorities have, however, already begun to execute a scheme for the sewerage, first of the central third of the city, and ultimately of the other two-thirds. A network of underground pipes already exists for the carrying away of rain water. There are strong grounds for suspecting that a great many houses have connected their drain pipes with these; it is certain that sewage in some way gains access to them. From the frequent and unusually large openings at the edge of the kerb-stone into these pipes a constant, excessively foul-smelling, visible

Digitized by Google

steam is seen to arise during frosty weather—that is to say, during half the year. It undoubtedly arises invisibly during the other half. It is this that has gained for Moscow the reputation among visitors of being a "smelly" city. At present it is impossible to deny that the charge is well founded, but the new system, if thoroughly carried out, should do much to remove the reproach.

The system adopted is the "separate system," in which one set of pipes will carry the rain water and another the sewage. The latter vary from six inches to seven feet in diameter, the smaller pipes being of earthenware and the larger of brickwork. The best method of ventilating and flushing sewers and drains has been the subject of prolonged consideration. Over three years ago three engineers to the city authorities were commissioned to visit Germany, Switzerland, and England to obtain the latest information on this question. In England they visited London, Wimbledon, Croydon, Oxford, Reading, and Dover. A full report of their labours was issued in Moscow after their return. I am indebted to M. Semenof, who was a member of this Commission, for most of the details here given of the new drainage system in Moscow. The same question was dealt with by another Commission under the presidency of M. Erisman, Professor of Hygiene in the Moscow University, and their very full and instructive report has been issued during the past few weeks. It contains, amongst other things, an account of exhaustive experiments upon the effect of extreme cold, such as occurs in the winter here, upon the usual arrangements for ventilating drains and sewers. The sewage matter will be conducted, under the new system, to a large area of land obtained for the purpose by the municipality, about twelve miles from the city. This area measures 1000 desiatins, or 2700 acres. The sewage will be disposed of on the principle of broad irrigation.

It will be seen from the above notes that, while the present sanitary condition of Moscow leaves much to be desired, extensive schemes of reform are already initiated. The coronation of the Emperor, which is fixed for May 6th (18th) next, and the International Medical Congress, which is, I learn, to be held here in August, 1897, will probably prove powerful stimuli to the rapid execution of these schemes.

The Twelfth International Medical Congress.

I have just learnt from Professor Erisman, the general secretary to the Congress, that the date fixed for the next International Medical Congress is the week beginning Aug. 19th and ending Aug. 26th (New Style), 1897. The official announcement will very shortly be sent to the English press. The Emperor has given his Imperial sanction to the Congress, and the Grand Duke Sergi Alexandrovitch, the governor of Moscow (and grandson-in-law to Queen Victoria), has granted it his patronage. The nominal president will probably be the Minister of Public Education; the acting president will almost certainly be Professor Klein, the Dean of the Faculty of Medicine in the University of Moscow. Professor Erisman, who holds the chair of Hygiene, has, as already stated, been elected general secretary. The meetings of the Congress will be held in the theatres and laboratories of the University Clinique, the so-called *klinitcheski gorodok*, or clinical townlet. Papers and discussions must be in either the French or German language; Russian has been excluded lest the Congress should become national rather than international, and English on the grounds that it is a language little used or understood by other than Englishmen.

Moscow, Nov. 24th (Dec. 6th).

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Dean Case.

IT cannot be said that the *dénouement* of the Dean case will add to the prestige of the medical profession, but rather will enforce the old proverb about "the cobbler and his last." It will be remembered that Dean was found guilty by a judge and jury of poisoning his wife, but that popular clamour induced Parliament to appoint a Royal Commission to reinvestigate the case, the Commission consisting of two medical men and one lawyer. The medical portion found that there were doubts as to Dean's guilt, and he was pardoned in consequence. The legal member dissented from the report of the Commission. Then the prosecutor for the Crown made a sensational statement to the effect that the solicitor for the defence had admitted that Dean had confessed his guilt, and Dean and his solicitor were arrested on a charge of conspiracy, and Dean was also charged with perjury. The druggist who sold him the poisons was discovered, the solicitor admitted that Dean had confessed, and Dean then himself admitted his crime, was found guilty of perjury, and is now undergoing trial, with his solicitor, for conspiracy. The medical problem still remains that Dean gave his wife both arsenic and strychnine, but she only exhibited symptoms of arsenical poisoning.

The Diagnosis of Leprosy.

In October, 1894, a supposed case of leprosy was sent from Rockhampton to Brisbane, with a certificate from two medical men that the patient was suffering from leprosy. He was there examined by four practitioners, and from serum expressed from a tubercle on the thigh the bacilli of leprosy were obtained, and the patient was sent to the leper lazaret at Dunwich. In July, 1895, as some improvement had occurred in the patient's condition, the Colonial Secretary instructed Mr. Pound, the Government bacteriologist, who is not a medical man, to examine the patient. He reported that he could find no bacilli, and the Colonial Secretary transferred the patient to another lazaret at Peel Island. At the August meeting of the Queensland Branch of the British Medical Association the action of the Colonial Secretary was discussed and criticised adversely. It was pointed out that as Mr. Pound was not a medical man and had no clinical knowledge of leprosy to enable him to select serum from proper situations for bacteriological examinations, his negative results were of no value, and the following motion was passed unanimously: "That, whereas a bacteriological examination forms an important part of the medical examination of a suspected leper, it is necessary that such bacteriological examination should be conducted by, or carried out under the immediate supervision of, a qualified medical practitioner."

Conference of Medical Staffs of the Hospitals for the Insane, Victoria.

In October was inaugurated the first of a series of conferences, which it is proposed to hold annually in Melbourne, of the medical staffs of the various hospitals for the insane in the colony. The subjects discussed were: 1. The training and examination of attendants and nurses, and their registering. It was decided that, in conjunction with the scheme of teaching of attendants now adopted, examinations should be held, and the results should largely influence promotions. 2. The equipment of the metropolitan asylums with apparatus for the prosecution of pathological work, and the appointment of a pathologist was approved. 3. It was decided to make a series of collective investigations on the subject of general paralysis of the insane, which was becoming increasingly prevalent.

Quacks and Indecent Advertisements.

Reference has been made in previous communications to the extent to which quackery flourishes in the colonies. Every newspaper is crowded with quack advertisements, which grow bolder and more indecent every year. The Medical Defence Association of Victoria recently waited on the Chief Secretary and urged upon him the necessity of introducing a Bill into Parliament to suppress such advertisements, and the various medical societies have passed resolutions in favour of such a Bill being passed. The quacks do not get it all their own way, however, in Victoria. One of them was recently charged with offences against the Medical Act, in that he pretended to be an apothecary and prescribed outside his open shop. It appeared that he was called in to see a woman who was suffering from an ovarian tumour. He, however, denied that she had a tumour and prescribed for her. She grew worse, however, and was subsequently operated on at a hospital with a fatal result. The first charge was held to be proved, and the quack was fined £5. He subsequently sued the husband of the woman for the value of the drugs supplied, but lost his case.

Nov. 6th.

ACCIDENT TO A MEDICAL MAN.—Last week whilst returning from seeing patients, Dr. T. Evans, the medical officer of health of Newquay (Cardiganshire), and his groom were thrown out of a dog-cart; both had a miraculous escape, but the horse had to be killed owing to the injuries it had received.

UNIVERSITY OF LONDON.—M.B. EXAMINATION.—The following have passed the under-mentioned examinations for honours (October, 1895):

MEDICINE.

FIRST CLASS.

Crookshank, Francis Graham (scholarship and gold medal) University College.
Salter, Alfred, (gold medal), Guy's Hospital.
Abrahams, Bertram L., B.Sc., University College.
Gillies, Sinclair, St. Bartholomew's Hospital.
Cook, John Howard, University College.

SECOND CLASS.

Shaw, Harold Batty, University College.
Cook, Albert Ruskin, B.Sc., Cambridge University and St. Bartholomew's Hospital.
Handley, William Sampson, Guy's Hospital.
Dimsey, Alfred, University College.
Harnett, Charles John, Guy's Hospital.
Sowry, George Herbert, St. Bartholomew's Hospital.
Pugh, William Thomas Gordon, Middlesex Hospital.
Walton, Herbert James, St. Bartholomew's Hospital.

THIRD CLASS.

Eastes, George Leslie, B.Sc., Guy's Hospital.
Every-Clayton, Leopold E. V., Guy's and London Fever Hospitals.
Rodocanachi, A. J., B.Sc., University College.
Thomas, Thomas Morrell, Guy's Hospital.
Sinigar, Harry, Mason College.
Despard, Rosina Clara, London School of Medicine for Women.
Hull, Charlotte Elizabeth, London School of Medicine and Royal Free Hospital.
Brook, Sydney Wilkinson, Owens College and Manchester Royal Infirmary.
Bodman, John Hervey, University College, Bristol, and St. Bartholomew's Hospital.
Traill-Christie, Margaret Marion, London School of Medicine and Royal Free Hospital.

OBSTETRIC MEDICINE.

FIRST CLASS.

Gillies, Sinclair (Scholarship and Gold Medal), St. Bartholomew's Hospital.
Handley, William Sampson (Gold Medal), Guy's Hospital.
Hopton, Ralph, Yorkshire College.
Cook, Albert Ruskin, Cambridge University and St. Bartholomew's Hospital.
Every-Clayton, Leopold E. V., Guy's and London Fever Hospitals.
Salter, Alfred, Guy's Hospital.

SECOND CLASS.

Cook, John Howard, University College.
Pugh, William Thomas Gordon, Middlesex Hospital.
Rodocanachi, Ambrose John, University College.
Bodman, John Hervey, University College, Bristol, and St. Bartholomew's Hospital.
Jewell, William Henry, Guy's Hospital.
Sowry, George Herbert, St. Bartholomew's Hospital.

THIRD CLASS.

Coleman, James Jordan, Guy's Hospital.
Dimsey, Alfred, University College.
Shaw, Harold Batty, University College.
Vellacott, Philip Northcott, Guy's Hospital.
Despard, Rosina Clara, London School of Medicine for Women.

FORENSIC MEDICINE.

FIRST CLASS.

Harnett, Chas. John (Scholarship and Gold Medal), Guy's Hospital.
Gillies, Sinclair (Gold Medal), St. Bartholomew's Hospital.
Abrahams, Bertram Louis, University College.
Salter, Alfred, Guy's Hospital.
Sinigar, Harry, Mason College.
Nicholson, T. Goddard, B.Sc., St. Thomas's Hospital.
Shaw, Harold Batty, University College.
Kirton, Reginald Gower, London Hospital.

SECOND CLASS.

Handley, William Sampson, Guy's Hospital.
Eastes, George Leslie, Guy's Hospital.
Hardenberg, Edward Fras. H., Guy's Hospital.
Hunt, Tom Harold, Owens and Yorkshire Colleges.
Pearson, Maurice Grey, B.Sc., St. Bartholomew's Hospital.
Vellacott, Phillip Northcott, Guy's Hospital.

THIRD CLASS.

Despard, Rosina Clara, London School of Medicine for Women.
Crookshank, Francis Graham, University College.
Cook, Albert Ruskin, Cambridge University and St. Bartholomew's Hospital.
Brook, Sydney Wilkinson, Owens College and Manchester Royal Infirmary.
Edmunds, Percy, James, B.Sc., University College.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Dührssen, *privat-docent* in Midwifery, has been granted the title of Professor.—*Budapest:* Dr. Janny, *privat-docent* in Surgery, has been granted the title of Professor.—*Innsbruck:* Dr. J. Nevinny has been promoted to the Ordinary Professorship of Pharmacology.—*Kiel:* Dr. K. A. Bier has been appointed Extraordinary Professor of Surgery.—*Palermo:* Dr. G. Rummo of Naples has been appointed Professor of Clinical Medicine; Dr. A. Monti of Pavia has been appointed Professor of General Pathology.—*Cracow:* Dr. B. Wicherkiewicz of Posen has been appointed to the chair of Ophthalmology.—*Munich:* Dr. Ludwig von Stubenrauch has been recognised as *privat-docent* in Surgery.

FOOTBALL CASUALTIES.—On Saturday last, during a match between two local clubs on the Bishop's Wood estate, Highgate, a player fractured his left leg.—In a match between the Cheltenham College and Clifton teams, a member of the latter team sustained severe contusions, and was admitted to the Cheltenham Hospital.—On Monday last, in the progress of a match at Tralee, a player, aged twenty-three years, after a scrimmage fell and died immediately.

TESTIMONIAL TO A MEDICAL MAN.—On Dec. 7th a meeting of about 300 friends and patients was held at the Lordship-lane Hall, Dulwich, S.E., to present Mr. John Rand, F.R.C.S. Eng., with his portrait on the occasion of his retirement from practice. The chairman, Mr. Matthew Wallace, J.P., said "this meeting and presentation were the result of a spontaneous expression of feeling showing the great regard, affection, and respect which were felt for Mr. and Mrs. Rand, not only in his professional but in their social and public life during the twenty-six busy years of their residence and work in Dulwich." The excellent portrait was the work of Mr. W. H. Margetson of Coventry Park.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Almeida Couto, Professor of Clinical Medicine in the University of Bahia.—Dr. Jas. E. Garretson, Emeritus Professor of Surgery in the Medico-Chirurgical College of Philadelphia.—Dr. Popoff, Extraordinary Professor of Physiology in the University of Dorpat.—Dr. Chas. F. Hersman, Professor of Clinical Medicine in the Missouri Medical College, St. Louis.—Dr. A. de Cerqueira Pinto, formerly Professor of Organic Chemistry in Bahia.—Dr. Bourienne, Professor of Clinical Midwifery in Caen.—Dr. Teichmann, formerly Professor of Anatomy in Cracow.—Dr. Ludwig Rütimeyer, formerly Professor of Comparative Anatomy in Basle.—Dr. H. Schmid, *privat-docent* in Odontology in Prague.

DIPHTHERIA IN LONDON.—The week ended Dec. 7th saw fatal diphtheria in London once again greatly in excess of the decennial average for the forty-ninth week. Last week the registered deaths in London numbered 69, as compared with 61, 69, and 63 in the preceding three weeks. The decennial average for the week in the years 1885–94 was exceeded by 25. The weekly average of deaths from the diseases in London during the period, Oct. 5th to Dec. 7th, was 65, as against 19 for the same period ten years ago. In the forty-ninth week of 1892 the registered deaths reached a total of 58, this being as many as 27 in excess of the decennial average 1882–91, and also the highest total on record. It will thus be seen how great have been the strides made by the disease of late. The deaths last week were all in young persons aged under twenty years. The sanitary areas credited with the largest share of the deaths were Greenwich with 8, Lambeth with 6, Hackney and Islington each with 5, and Camberwell and Clerkenwell each with 4 deaths. The malady seems to have shown some little disposition to diminish in amount, but not in intensity. Last week 114 cases were admitted to hospitals of the Metropolitan Asylums Board, against 104, 103, and 86 in the three preceding weeks; and the patients remaining under treatment on Saturday last numbered 694, as against 678, 688, and 691 on preceding Saturdays. The northern union of Edmonton and the West Ham Union had each of them experience of fatal diphtheria last week.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE EMPLOYMENT OF UNQUALIFIED ASSISTANTS, ETC., AND THE RESOLUTIONS OF THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—In the advertising pages of THE LANCET (Nov. 16th, 1895) a notice, printed under the heading "Important Notices," a series of resolutions which have been from time to time passed by the General Medical Council in regard to "covering" unqualified persons and the employment of unqualified assistants, and which with your kind permission I would like to ask those of your readers who are more intimately acquainted with the matter to make clear to me.

In making this inquiry I may mention that my attention has been more fully drawn to the subject by the comments which, on various occasions, you have made in your esteemed paper about this custom, &c. When reading these I always ask myself what the objects of the resolutions of the General Medical Council are if these are not applicable to the very abuses which they are intended to defeat, with the result that I invariably find myself divided between two opinions—viz., either that the Council purposed the resolutions to be good jokes, or else to be laws enforceable and binding on all qualified members of the profession, but impracticable for want of definition; in fact, laws in name, but not in reality. To find out whether or not one, or other, or any, of these views is right, or if the resolutions are of any value whatsoever, considering the way in which very many qualified practitioners utilise without let or hindrance their unqualified assistants in the working of their practices and in opposition to the apparent intention of the resolutions, is what I wish to draw attention to.

In the first of the resolutions which were passed by the Council on Feb. 27th, 1888, the opinion is expressed that "A registered medical practitioner would render himself liable to the censure of the Medical Council in case of the employment of an unqualified assistant in the practice of medicine, surgery, or midwifery on behalf and for the benefit of such registered practitioner, either in complete substitution for his own services or under circumstances in which due personal supervision and control are not, or cannot be, exercised by the said registered practitioner." This law, as you may observe, was not accompanied by any attempt to make a formal definition of the "misconduct in question," nor were the remaining laws, enacted at the same time, construed in any sense so as to enlighten anyone as to their real meaning, or for the guidance of such persons as might feel disposed to lay cases of reasonably suspected infringements of them before their compilers for inquiry and judgment. If the resolutions are real, what wonder is it that unoffending practitioners, anxious for their own preservation and of others, seem so apathetic and indifferent in trying to bring this evil to an end, when they are handicapped by the Council's indefinite resolutions. For example, does the resolution sanction, or will the Council infallibly censure, a registered practitioner who, when going away on his holidays, say for a month, leaves his unqualified assistant to absolutely carry on and conduct his practice in his absence, or who allows his unqualified assistant, without any kind of personal supervision whatsoever, to treat patients all through their illnesses, and to "do surgery" both at home and at branches, and to sign "club" and other certificates (not death certificates), &c.? Also, is it justifiable for a public vaccinator to depute his unqualified helper to perform all or any of the public vaccinations and then return the certificates of such vaccinations as having been done "successfully by me"; or for a medical officer of health to send his unqualified assistant to inquire into the causes of and to inspect cases of, infectious diseases notified by colleagues in his district; or for a principal to notify infectious diseases seen only by his unqualified assistant and then pocket the fee for doing so?

As to "covering," which is vaguely stated to be doing, or assisting in doing, or participating in doing, "any act which enables any unqualified person to practise as if he were duly qualified," what guarantee is there that a practitioner is liable to censure, or will be censured, who signs death certificates for patients seen only by his unqualified assistant, or for the latter to "fill in" in case of death occurring during his principal's absence from home on holidays, the principal, of course, having never visited the patient during his lifetime, or who merely "looked in" just before death, so as to be in a position to sign the death certificate if necessary, or who, when called into consultation by a "quack," meets him? Further, what of the unwritten prescribing, compounding, and booking of medicines by unqualified assistants?

In enumerating these acts I do not pretend to exhaust all the cases which might be brought forward in support of my charge of obscurity with which some of the principles on which our profession is based are enveloped. Sufficient, however, for my purpose have I quoted to show practically what a dead letter the resolutions of the Council are. I think the time has come for the sufferers to assert themselves and to try to compel by every fair means possible the Council to specify the misconduct in question.

Some persons will doubtless say, Why not forward reports of cases of suspected misdoings to be dealt with by the Council? Well, that course, I understand, has been pursued over and over again with a negative result, until now the mere mention of doing such a thing elicits the stock phrase, "Oh, what is the use of doing it, the Council won't do anything in the matter." If such an assertion be true, and is due, as stated, to a dislike to open the ball in any quarter lest by doing so persons in "high places," influential brethren and others holding important positions, &c., might in the general melée have to be assaulted, the sooner such a hugger-mugger policy is ended the better. Such a line of reasoning is suicidal. If every man cannot have his full pound of flesh by the present Council upholding consistently its own enactments—our rights and privileges—let us who are desirous of sustaining the character of our calling at least make an effort to rouse the Council from its slumbering, or else try if its members cannot be replaced by more practical men, and by men who will have the courage of their convictions.

I am, Sirs, yours faithfully,

Liverpool, Nov. 18th, 1895. R. HILL SHAW, M.B.

FLAGRANT ADVERTISEMENT.

To the Editors of THE LANCET.

SIRS,—For at least two years the enclosed advertisement has appeared weekly in the *People* newspaper. The label (also enclosed) is taken from a bottle of medicine supplied by the physician. The dispensary has painted upon the wooden portion of the front: "Dr. Fisher, M.R.C.S. L.R.C.P." The wire window-blinds are inscribed: "Ear, Liver, and Nervous Disorders." On looking through the window, may be seen two framed diplomas, and a notice—"This is not a free dispensary." No one resides upon the premises. In the neighbourhood a qualified gentleman named Fisher, holding the diplomas M.R.C.S. Eng., L.R.C.P. Ed., and L.S.A., does reside, as will be seen by referring to the Medical Directory.

I should be glad of an opinion from you as to whether it is justifiable for any medical man to issue such labels as the one I enclose, stating his fees. As to the advertisement in the newspaper I have named, I need say nothing.

I am, Sirs, yours faithfully,

Dec. 10th, 1895. OBSERVER.

*** We subjoin the advertisement, which, it will be seen, does not mention the name of the medical man, but gives the address, while the medicine label gives the same address and the name. We consider the whole to constitute what our correspondent has called it—a case of "flagrant advertisement," but we find no Dr. D. Fisher in the current Medical Directory or Register.—ED. L.

[*Advertisement.*]

NERVOUS DEBILITY DISPENSARY,
268, CITY-ROAD, E.C. (on the Canal Bridge).

NERVOUS DEAFNESS, Dyspepsia, Noises in Head, Loss of Vigour, and Genito-Urinary Diseases, &c., especially treated. THE PHYSICIAN attends 11.0 to 12.0 and 7.0 to 9.0; Sundays, 11.0 to 12.0 only. Weekly Subscription, 1s. to 2s. 6d. ADVICE AND MEDICINE BY POST.—"A genuine and successful institution."—MEDICAL REVIEW.

INFANT MORTALITY.

C.O.H.—The only possible method for the calculation of infant mortality, that is, of deaths under the age of one year, in any locality during any given period is to ascertain the proportion which such deaths bear to the births registered in the same locality during the same period. Any excess in this calculated proportion over the rate of 100 per 1000, or 10 per cent., represents excessive infant mortality in a small town. It should, however, be remembered that in a small population a month is far too short a period for the calculation of a trustworthy birth- or death-rate. The Registrar-General does not calculate or publish rates of infant mortality for any small towns; but in his quarterly return is invariably published the rate of infant mortality in each of a hundred English and Welsh towns, not one of which, however, has a population less than 30,0000 persons. This return also gives the mean rate of infant mortality in each quarter in England and Wales, and in England and Wales exclusive of the 100 large towns separately dealt with.

CORRESPONDENT sends us the following advertisement from the *Scotsman* of Dec. 10th:—

DOCTOR wanted at once for a country district where a large practice is obtainable. Applications, with testimonials, to be sent to A., 9, Scotsman Office, Aberdeen.

He considers, as we do, that for a medical man to post testimonials of his fitness to undertake a practice to an anonymous individual at the office of a newspaper would be a most ill-advised proceeding.

Dr. G. H. Broadbent's communication has been received and shall have our attention.

A. R. H.—The subject of this letter is not worth powder and shot.

THE CLIMATE OF THE EAST COAST OF AFRICA.

To the Editors of THE LANCET.

SIRS,—Can any of your readers let me know quickly if it would be an unhealthy voyage from Port Natal along the East Coast of Africa to the island of Zanzibar? Myself and some friends, one a delicate person, propose to make the trip, and we would probably be there in March next. We would coast it in a large steamer, calling at Delagoa Bay and Beira, these two places at least. If there would be any considerable danger to health from fever or any such causes, we would give up the idea. If you could kindly let me know I would be exceedingly obliged, as we find a difficulty in obtaining reliable information on this point.

I am, Sirs, yours respectfully,

Dec. 10th, 1896. VOYAGER.

"ADVERTISING."

To the Editors of THE LANCET.

SIRS,—Referring to the accusation brought against me by an inquiring gentleman of Canonbury, I shall be glad if you will publish the following: The cards copied in your journal were sent by me to the members of a society (club) to which I am the medical officer, and to no one else. It is therefore quite untrue to suggest that they were 'circulated freely," as they were addressed to the members of this society only (the Hebrew Tontine Benefit Society)—i.e., to my own patients, and enclosed in envelopes.

I am, Sirs, yours obediently,

Houndsditch, E.C., Dec. 13th, 1895. M. BERNSTEIN, M.D.

A. B.—It is doubtful if our correspondent could recover his fee in a county court, though he has undoubtedly been treated badly. How far he would have a good case legally would depend upon the exact way in which the arrangement was made and the amount of clear proof that he could bring in support of its existence. While sympathising we are strongly of opinion that whatever the circumstances no such action should be brought.

"THE BRITISH MEDICAL BENEVOLENT FUND."

To the Editors of THE LANCET.

SIRS,—May I ask you kindly to allow me to acknowledge through your columns the following additional donations to the British Medical Benevolent Fund?

Mr. Raland...	£1	1	0	"A Friend," per Dr. Barnes of Carlisle ...	£100	0	0
Mr. Herbert Allingham	2	2	0				
Dr. Gervis...	10	10	0				

I am, Sirs, yours faithfully,

W. H. BROADBENT.

84, Brook-street, Grosvenor-square, W., Dec. 11th, 1895.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Will any of your readers tell me which is the best form in which to administer strychnine hypodermically for snake-bite? It is very insoluble, and the necessary dose would mean a large quantity of fluid. What has been found the best dose?

I am, Sirs, yours truly,

Dec. 9th, 1895. ZAMBAAN.

MEDICAL ADVERTISEMENTS IN AUSTRALIA.

CANCER and TUMOURS.—A wonderful and natural remedy for cancers and tumours. Pamphlet on the subject post-free on receipt of 4*d.* in stamps. References.—Apply, A. M'Kee and Co., City Medical Hall, Adelaide-street, Brisbane.

DISTRICT MEDICAL CLUB, 515, Elizabeth-street, N., Market-buildings, daily 2 to 3 and 7 to 9 P.M. All diseases treated. Advice and medicine, 2*s.* 6*d.*—Dr. Maloney, surgeon.

ELECTRIC PILLS.—For Nervous Debility, Weakness, Incapacity, Loss of Vital Power, &c. (Dr. Laseurs, M.D., Paris, one of the Greatest Specialists in the world). Electric Pills are the most speedy and the most powerful remedy in the world. One box will be sufficient, and in even the weakest, the oldest, the most shattered, works a miracle, while perfectly harmless, leaving no bad after effects. Guaranteed never to fail. Worth their weight in gold. Price, 10*s.* 6*d.*, post free, from the sole agent, W. PARSONS, Chemist, 68, Bourke-street, E. Melbourne.

NERVOUS DISEASES! SYPHILIS!! VIRILITY!!!—Dr. L. L. SMITH, L.S.A. Lond., the only legally qualified medical man advertising! To those suffering from early practices. To those about to marry. To those married yet childless. To the Nervous. To the Prostrated. To those who have lost all energy. To those suffering from loco motor ataxis and paralysis. To those suffering from cerebro spinal irritation. To the Impotent!!! To those whose blood contains impurities. CONSULT DR. L. L. SMITH, 41, Collins-street.—Fee by letter, £1. Personal Consultation, Mornings and Evenings. Fee, £1 1*s.*, including two days' medicine.

NERVOUS SUFFERERS.—A new discovery; the very worst of cases; all nervous secret disease.—Jason, Box 124, G.P.O., Melb.

SURGEON LANGSTON, M.R.C.S. Eng., 121, Collins-street East. Every man who is weak, nervous and debilitated should consult this reliable old surgeon, over forty years' experience. Nervous and Physical Debility, Exhausted Vitality, Premature Decline, and all diseases and weaknesses of men. Consultation free, expert treatment, inviolable secrecy, and certain cure. Hours, 10 to 4 daily. Monday, Wednesday, and Saturday evenings, 7 to 9. SURGEON LANGSTON, M.R.C.S., 121, Collins-street, Melbourne.

THE POOREST MAN in the country can write to us and receive by return mail (free of charge) in a plain, sealed envelope, full directions for a speedy, permanent, and private home cure for all nervous and debilitating diseases.—Address to Foreign Novelty and Agency, P.O. Box 347, Sydney.

The above extraordinary advertisements speak for themselves. We are told when commenting on this kind of thing that it occurs away from home, and that under different conditions a different code of ethics must prevail; but that this is not so is proved by the fact that most of our colonial brethren shrink from advertising and hold fast by the honourable tenets of the profession. What most can do all can do, and the conduct of practitioners who indulge in this grossly unprofessional method of bringing themselves before the public is most reprehensible. The M.R.C.S. Eng. and the L.S.A. Lond. have got into company which should make them blush.

Medicus has not given us sufficient particulars to warrant our giving him a definite answer. Who said what? And when? We presume that whatever the occasion the medical officer had the right of reply, and that his defence would receive the same publicity as the reflections upon him.

Inter Cornua has placed before us two alternatives. He appears to consider that either way he must be wrong. We should say that either way he would be right, and that style which he uses is a matter for his private taste.

"THE PHONENDOSCOPE."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, "W.," in THE LANCET of Nov. 30th, we shall be pleased to send him a phonendoscope on trial for a few days; or it can be seen and tried at any time at either of our addresses. We are, Sirs, yours faithfully,

55, Grosvenor-street, W., Dec. 6th, 1895. HOOPER AND CO.

THE BEST ANGLO-FRENCH MEDICAL DICTIONARY?

To the Editors of THE LANCET.

SIRS,—Can any of your readers let me know through the columns of THE LANCET which is the best English and French dictionary of medical terms? I am, Sirs, yours faithfully,

Dec. 4th, 1895. C. S. J.

THE TROPICAL DISEASES OF WEST AFRICA.

To the Editors of THE LANCET.

SIRS,—Would you let me appeal to your readers to furnish me with the title of a good text-book of tropical diseases as met with in West Africa. I am, Sirs, yours truly,

Dec. 11th. A. A. S.

ERRATUM.—In our review of Dr. Jackson's book, "Skiascopy and its Practical Application to the Study of Refraction," which appeared in our columns on Nov. 30th, we omitted to mention that Messrs. Kegan Paul, Trench, Trübner, & Co., Limited, are the London agents for the publication.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière Asnieres, Paris.

The Action and Use of Some New Synthetic Remedies.

DERMATOL.

SINCE the first communication on Dermatol, appearing in No. 24 of the *Berlin. Klin. Wochenschrift*, 1891, many reports on the new remedy have been published both at home and abroad. Further investigations in various directions seem not only to have established many of the early claims made for Dermatol, but also to have indicated fresh fields of usefulness for it.

The physical characteristics of Dermatol are now well known. It is a fine yellow powder, unaltered by exposure to light and air, insoluble in ordinary re-agents, free from taste, and entirely without odour. The latter property is especially esteemed by patients on whom the employment of strong-smelling antiseptic powders like Iodoform would entail serious inconvenience. The insolubility of Dermatol prevents its absorption, and therefore it never produces any toxic effects, even when employed in large quantities under conditions most favourable for absorption.

A further characteristic of Dermatol is the absence of irritating properties. The unpleasant symptoms that sometimes follow the use of dressings such as Iodoform, Corrosive Sublimate, &c., are never observed with Dermatol. It has been shown that by the intimate admixture of Dermatol with septic nutrient material, the development of bacterial growths is arrested. Dr. Bluhm (*Therap. Monatshefte*) has tested its bactericidal power upon twelve different kinds of bacteria, comparing the results with those obtained from Iodoform, and finding the polyseptic action of Dermatol far superior to that of its repugnant predecessor.

It is more especially indicated as an absorbent, antiseptic powder for the treatment of fresh surgical wounds, slight accidental cuts, or old non-purulent wounds. When applied as a dusting powder it rapidly absorbs the secretions from wounds of these types, and forms a very hard, dense, and closely adherent crust, hence it proves extremely useful in all cases in which astringent and drying effects are desired. It has been reported valuable in crushed and lacerated non-septic wounds, burns, and scalds, and in large crural ulcers. Before the introduction of Dermatol it was impossible to close a sewn rectal or fistular wound with any degree of security. Now, this valuable chemical forms a protective crust in a short time, under which primary healing progresses. The result is not less satisfactory in operations for prolapsus, and in rectal plastic surgery.

In gynæcological practice it is attracting a great deal of attention, in view of the reports presented to the Bonn Gynæcological Congress. Remarkably satisfactory results were reported to have been obtained by its use in the treatment of laparotomy wounds, prevalent carcinomata, myomata, deep-seated tuberculous peritoneal abscess, and in infectious catarrhs of vagina, cervix, or endometrium. This report referred to, after calling attention to the superiority of Dermatol over Iodoform, concludes: "Dermatol is absolutely unirritating, powerfully antiseptic, astringent, odourless, stable, and non-hydroscopic."

In dermatological practice it is highly recommended in the form of a 10 per cent. ointment with Lanoline for eczema in children, intertrigo mammæ, and intertrigo ani. It has been tried with excellent results as a dusting powder in dysidrosis of the hands and feet, in balanitis, in operations for phimosis, and, in alternation with antiseptic and stimulating remedies, in the treatment of bubo. For burns the 10 per cent. Lanoline ointment above mentioned is highly recommended.

Dermatol has been used with excellent results in otitis media suppurativa, otitis externa, and in a large number of cases of chronic middle-ear suppuration. The secretion was quickly reduced in quantity, and "most of the cases ceased suppuration after a few insufflations." In otitis externa it was employed (*Therap. Monatshefte*, 1892, No. 12) with excellent results. After two to five applications of the powder the aural cavity was dried, the swelling reduced, and the eczema healed. When used to check a purulent aural discharge insufflations should be alternated with irrigations with an antiseptic solution, such as that made by dissolving a "Soloid" of Iodic-Hydrarg. in a pint of water.

In ophthalmic work it has been used in the after-treatment of operations, and Dr. Werther reports successful results with Dermatol in phlyctanular inflammation of the conjunctiva in scrofulous children. It is an advantage that Dermatol can be employed for scrofulous patients simultaneously with potassium iodide, which is contra-indicated in conjunction with calomel.

Dermatol supplied to the Medical Profession in 1 oz. tins at 1s. 2d. each. For the internal administration of Dermatol, "Tabloids" containing 4 gr. each are recommended as the most convenient form for administration, and are supplied to the medical profession in bottles of 24 and 100 at 8d. and 2s. each.

PHENOSALYL.

This is a clear, syrupy liquid, consisting of a mixture of Benzoic, Salicylic, and Carbolic Acids, melted together and dissolved in Lactic Acid. The results of all bacteriological trials with the mixture have shown that it possesses an antiseptic power considerably superior to that of carbolic acid; these trials dealt with the respective micro-organisms peculiar to the following diseases:—Cholera, Anthrax, Pneumonia (Fraenkel), Bacillus Pyocyaneus, Typhus (Eberth), Diphtheria, Tuberculosis, and with Staphylococcus Pyogenes Aureus. The results of these trials were completely satisfactory; even the last-named bacterium (which is the most resistant known) is immediately killed by a 1 per cent. solution, whilst to attain the same result with carbolic acid it is necessary to expose it to the action of a 2½ per cent. solution for at least one minute. Phenosalyl has been used by Duloroy in the sterilisation of instruments, of gauze, and of different organic substances like blood, as well as of decomposing urine and the saliva of consumptives, with most encouraging results. The numerous tests to which Phenosalyl has been subjected show that, while it kills the bacteria of pus after one minute's contact, it does not irritate the skin, nor has it any corrosive action on instruments. A communication by Professor Fraenkel summarises the advantages of Phenosalyl over other antiseptics as follows: Easy solubility in water; no danger of toxic symptoms; a pleasant and non-persistent odour which does not cling about the hands or clothes. Solutions of Phenosalyl have no corrosive action on the skin, the mucous surfaces remain smooth and slippery, and do not become dried up, as is the case after washing with carbolic acid or corrosive sublimate. Supplied to the Medical Profession in 2-oz. bottles at 10d. per bottle.

The above are produced by the Farbwerke, vorm. Meister, Lucius, and Brüening, Hoechst-am-Main, and specimens may be had, as well as literature bearing on these and other new products, upon application to the agents.

FERRIS & CO.'S PATENT "EVER-READY" CADDY

AND

"Ever-Ready" Plasters and Dressings.

The "Ever-Ready" Cylinder Wound Plasters and Dressings for the Patent Caddy are supplied at rates which compare favourably with the prices charged for the old style of plasters, lints, &c.

The "Ever-Ready" Dressings SAVE WASTE, and are consequently CHEAPER TO USE.

"EVER-READY" PLASTERS

Cylinder wound in one continuous piece, 8 inches wide, spread on calico, swansdown, or felt, in rolls of 2 to 6 yards, according to material. Tape plasters, various widths, on spools.

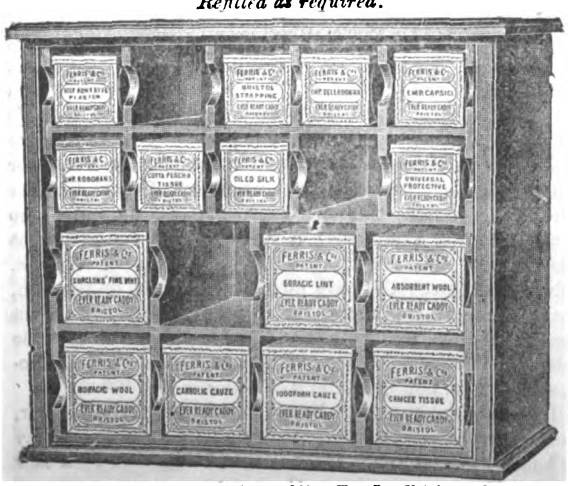
"EVER-READY" PROTECTIVES

Cylinder wound, 8 inches wide. Gutta Percha Tissue 12 yards on a roll. Oiled Silk, Jaconet and other protectives, 6-yard rolls.

"EVER-READY" LINTS

Half-pound rolls, cylinder wound in one continuous piece, 8 inches wide. All kinds of plain and antiseptic lints in stock.

"EVER-READY" ANTISEPTIC GAUZES



Cylinder wound, 12 yards (full width) on each roll.

"EVER-READY" WOOLS

Cylinder wound, in rolls about 6 to 8 oz. each, 8 inches wide. Absorbent wools, antiseptic wools, Gamgee tissue, &c.

The PATENT CADDY is made in Two Sizes, to suit different kinds of Dressings.

Each Dressing is Fitted in a separate Caddy, which can be Refilled as required.

MAHOGANY CABINET, holding Ten Small (A) and Eight Large (B) Caddies.

From the MEDICAL ANNUAL, 1895, p. 558.

"We thank Messrs. FERRIS & Co. of Bristol, for having solved a question which concerns us much more deeply than most of the great political questions with which the general public trouble themselves. How is the practitioner to keep his stock of lint, cotton wool, adhesive plaster, strapping, oil-silk, waterproof sheeting, antiseptic dressings, &c., &c., in anything like order, so as to be able to find whichever is required when he wants it, and so that the several articles do not spoil as a result of the haste and waste of every-day practice? Messrs. FERRIS & Co. deal with this question by putting each dressing on a cylinder and enclosing this cylinder in a tin box which they call a "Caddy." At the end of the Caddy the name of the dressing is distinctly printed. They next produce a wooden cabinet, having pigeon-holes which fit the Caddies, and these when placed in position, with the name distinctly marked at the end, enable us at once to pick out the desired dressing. The box is opened, the required quantity pulled from its reel and cut off, and the remainder is untouched and cannot soil however long it may remain.

"There is no place for the "Caddy" but its vacant pigeon-hole, so that if a dozen of the most untidy assistants or nurses were using from the same cabinet, it would be impossible for any dressing to be out of its place or spoiled by careless usage. Busy practitioners will agree with us about the practical importance of this. Some of us who are fairly tidy in our habits, so far as the limits of time allow, know too well the feeling of doubt and uncertainty with which the drawer in which the dressings are kept is turned over, and sometimes we find it, but often—*'mais nous avons changé tout cela.*"

"We can only express our sympathy for those who do not know of these useful and inexpensive Caddies, which are supplied separately, and adapt themselves to the practitioner's own shelves or cupboards, although for the reason we have mentioned we would recommend a cabinet where each Caddy has its place."

A Set of Dressings in the Patent Caddies sent on approval to any member of the Medical Profession, carriage free.

The following are taken from our List of upwards of seventy varieties of Dressings:—

LIST NOS.		PRICE.
No. 11T	Caddy and Set Spools Antiseptic "Self-Adhesive" Rubber Tape Plaster, assorted widths	7/6
No. 6	Caddy and 6 yard roll "Bristol" Strapping	2/8
No. 74	Caddy and half lb. roll Fine Lint ...	2/3
No. 145	Caddy and roll Sal Alembroth Wool	2/-
No. 107	Caddy and 12 yard roll Double Cyanide Gauze	4/-
No. 69	Caddy and 6 yard roll Universal Protective	3/6

SAMPLE CADDY SELECTED FROM ABOVE SENT POST FREE ON RECEIPT OF REMITTANCE.

A Lecture
ON
PREVENTIVE INOCULATION AGAINST CHOLERA IN INDIA.

Delivered at the Examination Hall, Victoria Embankment, on Dec. 18th, 1895.

BY W. M. HAFFKINE, D.Sc.

[ON Wednesday afternoon last Professor Haffkine, who is staying temporarily in England, acceded to a request from the Royal College of Physicians of London and the Royal College of Surgeons of England that he should deliver in the Examination Hall of the Conjoint Board an account of his well-known work in India in the matter of the prevention of cholera by inoculation. The chair was taken by Sir J. Russell Reynolds, Bart., President of the Royal College of Physicians of London, and Professor Haffkine entered with the President. Both gentlemen were received with cheers by an expectant audience, far below numerically, however, what might have been expected. Professor Haffkine said:]

The virulence of pathogenic bacilli varies greatly, and in this fact is to be seen the explanation of mild and severe epidemics; and from this, no doubt, arose the practice of preventive inoculation; when a mild epidemic occurred everyone tried to take the disease, seeking close contact with infected persons, and, later, the virus itself was applied to give a mild attack; but, unfortunately, very often what looked like a mild form of the disease was really a severe form occurring in a very resistant subject, hence very severe epidemics arose, so that it has come to pass that legal proceedings are now taken against those who practise this method.

In small-pox, rabies, and syphilis, where the microbe is transferred directly from case to case, and leads no existence outside the human body, great variations in the virulence may be observed, but this is still more the case in those bacteria which lead a saprophytic life; and there appears to be no limit to the variations in virulence that may occur, and not merely variations in virulence, but in shape and size. Thus the cholera bacillus, as the field of investigation grew larger, was found to vary from a comma to a straight bacillus, and from what was little more than a micrococcus to a long, thin bacillus; usually it was harmless to birds, but at times birds were affected by it. The position and number of cilia also varied. Metchnikoff has found that its initial strength may be seventy-five times greater than when the virus has become weakened. The terms used are employed as in small-pox. The infectious material from a patient affected with the disease is a virus, and the process is called variolisation; this was the Eastern practice. On the other hand, the substance cultivated under conditions which will keep the microbe in a fixed state of virulence is a vaccine, and the process is vaccination. It is the difference between vaccination and variolisation which distinguished the method I have employed in India from that used in Spain by Dr. Ferran in 1885. Dr. Ferran injected bacteria from cases of cholera, and the results were so unfortunate that the method was forbidden by the Spanish authorities, and similar disasters have led to the use of any form of cholera inoculation being forbidden in Russia. The method which I have employed in India is on the same lines on which Jenner and Pasteur worked—that is to say, the use of a modified virus. A great difference between the two methods is to be seen in the fact that Jenner's method has survived a hundred years of trial. When Toussaint began to inoculate against anthrax he used the unmodified virus from cases suffering from the disease and the results were exceedingly disastrous, but Pasteur's inoculation against the same disease were with the modified virus, and were eminently successful. In the case of rabies also, preventive inoculation by an attenuated virus had now been used for ten years, and had been applied to many thousand people in France alone. I have abstained from using sterilised cultures in all my inoculations in India, because the effect is very much more evanescent and less trustworthy. The method which I have worked out is to give two injections:[1] the first injection is of a mild form, and the second is one whose virulence has been strengthened. This is given after an interval of five days. The full effect of each is not attained until five days have elapsed, so that the individual is not fully protected till ten days after the first inoculation. The microbe is cultivated under fixed and suitable conditions and its virulence is known, so that it can be used with certainty and safety. One-twentieth of a culture tube has been adopted as the standard dose. The amount of reaction is in direct proportion to the dose, and the amount of protection is in direct proportion to the intensity of the symptoms produced. A slight swelling and pain in the side are the usual local signs, and there is a slight rise of temperature. The amount of pain and fever are in direct proportion to the intensity of the symptoms produced. It is a matter of vital importance that the operator should be master of the strength of the virus used and know exactly the amount of power contained in a given dose.

And now we come to the record: 70,000 injections were made on 42,179 individuals without a single instance of mishap or accident of any description produced by our vaccination. My work in India lasted twenty-nine months—from April, 1893, till the end of July, 1895. The Indian cholera vaccination was applied in ninety-eight localities in the North-West Provinces and Oudh, in the Punjab, in Lower Bengal and Behar, in the Brahmaputra Valley and in Lower Assam, and during this time there were inoculated 294 British officers, 3206 British soldiers, 6629 native officers, non-commissioned officers, and soldiers, 869 civil Europeans, 125 Eurasians, and 31,056 natives of India. No official pressure has been brought to bear upon the population, and persuasion only has been used. In some localities efforts have been made to apply the inoculation to large parties of people living under similar conditions in order that comparison might be made between the inoculated and the uninoculated belonging to the same unit of population. The inoculated people belonged to sixty-four British and native regiments, to nine civil gaols, to forty-five tea estates, to the fixed agricultural population parallel to the Hurdwar pilgrim road, to the bustees of Calcutta, and to a certain number of boarding schools, orphanages, &c., and in the vast majority of cases the inoculated people lived under the direct observation of the military and sanitary authorities of India. Cholera has occurred in the inoculated localities from one to 459 days after the operation, and careful statistics have been immediately collected by the civil and military medical authorities in regard to both inoculated and uninoculated. The results can be grouped into three categories: (1) unsuccessful results, or those where any definite conclusion is impossible; (2) results slightly favourable to the method: and (3) satisfactory results. To the first-class belong observations made in a certain number of tea estates in Assam. The coolie workers live in very isolated bodies and remain unmixed with the general population. The whole of the cases underwent the first part of the treatment only—that is, inoculation with the maximal dose of the first vaccine. Cholera occurred in from one to six months after vaccination. The second inoculation was not made till after the cholera season. At Adam Tila, of 657 non-vaccinated no cases of cholera occurred, and of 318 vaccinated there were 2 cases (0·63 per cent.) with 1 death (0·31 per cent.). At Kalacherra, of 520 non-vaccinated there were 4 cases (0·77 per cent.) with 3 deaths (0·58 per cent.), and of 211 vaccinated there was 1 case (0·47 per cent.) with 1 death (0·47 per cent.). At Chargola, of 1007 non-vaccinated, there were 3 cases (0·30 per cent.) with 1 death (0·10 per cent.); and of 291 vaccinated there were no cases. At Pallarbund, of 1170 non-vaccinated there were 2 cases (0·17 per cent.), with 2 deaths (0·17 per cent.); of 451 vaccinated there were no cases. At Lungla, of 2050 non-vaccinated, there were 3 cases (0·15 per cent.) with 3 deaths (0·15 per cent.); of 421 vaccinated there were no cases. At Burnie Braes, Loobacherra, Kalaincherra, and Sandhura the number of vaccinated is not stated, but 11 cases occurred with 5 deaths. No cases are reported among the 677 vaccinated. To the second class belong observations made on cases where the results are slightly favourable. The results are divided into two groups. In the first maximal doses of the first vaccine only were used and cholera occurred in from

[1] Professor Haffkine explained the method of preparing anti-choleraic vaccine in a former lecture delivered on Wednesday, Feb. 8th, 1893, and reported in THE LANCET of Feb. 11th, 1893.

Digitized by Google

two to six days after vaccination in the Manchester Regiment and three months and a half after in the case of the Degubber tea estates. The statistics are as follows: In the 2nd Battalion Manchester Regiment, at Dinapore, of 729 non-vaccinated there were 6 cases (0·82 per cent.) with 3 deaths (0·41 per cent.); 193 were vaccinated and there were no cases. At Degubber tea estate in Assam, among the 228 non-vaccinated 2 cases occurred (0·88 per cent.) and 1 death (0·44 per cent.), and no cases were reported among the 387 vaccinated. The second group of observations were made on cases inoculated with weak doses of both vaccines, cholera occurring from 13 to 15 months after operation. Among the British troops in Cawnpore, of 797 non-inoculated there were 19 cases (2·38 per cent.) with 13 deaths (1·63 per cent.), and no cases occurred among the 75 inoculated. In the East Lancashire Regiment at Lucknow, of 640 non-vaccinated there were 120 cases (18·75 per cent.) with 79 deaths (12·34 per cent.), and of 133 vaccinated 18 cases (13·53 per cent.) with 13 deaths (9·77 per cent.). The last class contains observations with satisfactory results. These have been grouped into four parts. In the first group maximal doses of the first vaccine only were given, cholera occurring in from one to three months after vaccination. At the Karkurie tea estate, of 203 non-vaccinated there were 5 cases (2·46 per cent.) with 2 deaths (0·98 per cent.), and of the 709 vaccinated 1 doubtful case (0·24 per cent.) with 1 death (0·24 per cent.). At Kalain tea estate there were 1375 non-vaccinated with 23 cases (1·67 per cent.) and 11 deaths (0·8 per cent.) and of 681 vaccinated 2 cases (0·29 per cent.) with 1 death (0·15 per cent.).

The second group contains cases where small doses of both vaccines were given, cholera being prevalent during vaccination. At Gaya gaol during the first period of five days necessary for the full effect of the first vaccine, of 210 non-vaccinated there were 7 cases (3·35 per cent.) with 5 deaths (2·38 per cent.), and of 212 vaccinated 5 cases (2·36 per cent.) with 4 deaths (1·89 per cent.). During the second period of five days necessary for the full effect of the second vaccine, of 197 non-vaccinated there were 9 cases (4·57 per cent.) with 4 deaths (2·03 per cent.), and of 206 vaccinated 3 cases (1·46 per cent.) with 1 death (0·48 per cent.). During the last four days of the epidemic, of 192 non-vaccinated there were 3 cases (1·56 per cent.) with 1 death (0·52 per cent.), but no cases amongst 201 vaccinated. The total shows 2·56 times fewer cases and 2·05 times fewer deaths amongst vaccinated than amongst non-vaccinated. The difference in the results in the Gaya gaol during the first five days is very slight, and points out the absolute similarity of conditions under which the inoculated and the uninoculated lived.

The third group includes cases with medium doses of both vaccines. The observations extended over 459 dates after vaccination. In Calcutta the comparison between the uninoculated and inoculated has been made exclusively among members of the same families living under the same conditions of life. Observations during 459 days after vaccination were made in the bustees of Calcutta, and middle doses of one and of both vaccines were given. Of eight houses with inoculated people affected during the first period of five days after the first injection there were 5 cases among 75 non-vaccinated (6·66 per cent.) with 3 deaths (4 per cent.) and 3 cases among 52 vaccinated (5·77 per cent.), with 3 deaths (5·77 per cent.). Of two houses with inoculated people affected during the second period of five days necessary for second vaccination there were 2 cases among 8 non-vaccinated (25 per cent.) with 2 deaths (25 per cent.), and no cases among 17 vaccinated. Of twenty-six houses with inoculated people affected between the 11th and 459th day after vaccination there were 38 cases among 263 non-vaccinated (14·45 per cent.) with 34 deaths (12·93 per cent.), and 1 case (in a child which had not been brought up for the second inoculation) among 134 vaccinated (0·75 per cent.) with 1 death (0·75 per cent.).

The last observation (the fourth group) came from Assam, and was received only a few days ago. The full account has not yet reached me, but the preliminary note runs as follows. In Assam, Surgeon-Captain Hare, my co-worker, is continuing these inoculations for the Assam Government, under whose direction all coolies for the Assam-Burma Railway Survey have been collected and sent under an escort. Cholera had broken out amongst the coolies, and Surgeon-Captain Hare immediately applied the inoculation. The result is as follows: Amongst the uninoculated there were 34 cases with 30 deaths, while amongst the inoculated, which formed the larger part, there were only 4 fatal cases.

It appears that in instances where cholera has made the largest number of victims, and where it has sufficiently spread so as to make it probable that the whole population were equally exposed, the result has been invariably favourable to inoculation. Applied during the existence of the epidemic it tends to reduce the mortality even during the first ten days. In Lucknow there was a difference in the number of cases attacked of between 18 and 13 per cent., and in the deaths of between 12 and 9 per cent. The best method is probably to use doses of both vaccines, the second one being kept at the highest strength attainable. The evidence collected up to now is decidedly in favour of inoculation, and my own conviction is strengthened more and more. My responsibility, however, forces me to point out that the number of observations is not yet very large, and that it is desirable to have the results confirmed by more and more information. I hope you will pardon me if I quote the opinion of Koch, whose discovery was the starting point of our inoculation for cholera. He says "the demonstration is complete; the protective power of the method is established finally by the observations collected in India up to now; further perfections and simplifications may be possible, but the main question at issue, the chief part of the problem, is solved by the facts recorded in your report to the Government of India." I quote this by his permission. Many very interesting curative methods by serum injection have been introduced during my absence from England. Treatment by antitoxins must be considered a decided success, but it cannot be used as a preventive treatment, as its effects on the system are very rapidly worn out. Neither the anti-diphtheritic serum nor the anti-cholera serum lasts more than a few days. The treatment stands otherwise in regard to people affected already. On my return to India I intend to make an extensive trial in connexion with the physicians of the country and with the help of Professor Pfeiffer of Berlin, who has put at my disposal his experience on the subject and a supply of antitoxic serum. In case it proves a failure—and there is danger of the patient succumbing before the antitoxin can have its effect—I intend to combine it with transfusion of saline fluids. It is possible that the administration of antitoxic serum will mitigate the symptoms and it is possible that its administration will diminish the active protection afforded by the vaccines. A series of experiments have been undertaken in the Netley Bacteriological Laboratory.

On the day I came back from India I found Pasteur lying on his death-bed. Whatever might have been his appreciation of the work, I have only one desire—that the whole of the honour that may come from my efforts should be referred to his sacred memory. To the Government of India, the officers of the India and Army Medical Staff in India, to Professor Hankin in Agra, to Dr. Powell of Cuchar, and to Dr. Simpson, the well-known health officer of Calcutta, I address my hearty expressions of gratitude for the assistance they have given me in carrying out my work. I beg them to accept this public acknowledgment that without their help I should never have been able to accomplish in India the smallest part of what I have done. I also beg to thank the chairman and the organisers of this meeting for having given me this opportunity of making this communication.

[At the conclusion of the lecture Sir J. Russell Reynolds said he could not let that lecture come to an end without saying on behalf of his colleagues how deeply they were indebted to Professor Haffkine for having done such good work, and for having come there and given them such a lucid exposition of the way in which the work had been done. They congratulated him most heartily for the success which had attended his labours, and hoped that in the future a still greater amount of success would follow. He congratulated the lecturer on another point. Before Professor Haffkine entered the lecture theatre he had told him (Sir J. Russell Reynolds) that he could not speak English. After hearing Professor Haffkine deliver the lecture, however, he thought he had spoken it remarkably well.]

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Professor Alexander Fraser, having passed the necessary examinations, has been admitted a Fellow of the College. Mr. Richard Keatinge, L.R.C.P.I. and L.S.A. Lond., having passed the necessary examination, has been admitted a Licentiate to the College.

An Introductory Address
ON
THE SENSES: THEIR USE AND CULTIVATION.

Delivered at St. Mungo's College, Glasgow,

BY FRANCIS H. NAPIER, F.R.C.S. ENG., M.B., B.S. LOND., F.F.P.S. GLASG.,
OPHTHALMIC SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

GENTLEMEN,—We are met to-day to inaugurate the commencement of the winter session, and it is my first duty, and a very pleasant duty too, to give to the students, one and all, a very hearty welcome; and in this welcome I speak not only for myself, but I have also the honour to be the mouthpiece of the governing body of the College and of my colleagues of the teaching staff. We are glad to meet again the older students, invigorated, it is to be hoped, by the vacation just drawn to a close, and returning to their studies with renewed ardour. We are glad also to see amongst us for the first time the faces of those who are on the threshold of their medical studies. We congratulate them on their choice of a profession, not because that profession leads to any considerable pecuniary emolument, but because, with good and honest work, it opens up a prospect of a sufficiency to live upon, and gives a boundless opportunity of alleviating the sufferings of those less fortunate than ourselves. Now, gentlemen, when I was asked to deliver the inaugural address this year, I must own that I felt at a loss; for though deeply sensible of the honour of being invited to undertake it, I was at the same time fully conscious of the difficulty of the task before me. I recognised how limited was the choice of a subject. I take it that the inaugural address should be delivered to the student, and primarily to the first-year student. It should not, therefore, be too technical in character, for that would confine its interest to the few; and, on the other hand, it is difficult to find a subject of general interest which has not become hackneyed by constant repetition. The subject of medical education is, of course, one that will exercise a never-ending fascination on all of us, and is of peculiar interest on such an occasion as the present, but on that topic you were addressed not long since in an exhaustive and able manner by one of my colleagues, so I definitely determined to abandon it. After much consideration I decided to collect a few of the well-known and recognised facts and theories relating to the senses, with the object of seeing what bearing they have upon our profession. I do not hope to present to you anything new or original, for, after all, there is little that is new in the world either of thought or reality. The great philosophers of the Greeks—Socrates, Plato, and Aristotle—had dipped into the realms of speculation as deeply as any of our modern thinkers; but I do trust to be able to put before you, briefly and compactly, some of these thoughts of all times, clothed in such a fashion as to draw out more pointedly the special lessons that they hold for us in our professional requirements.

What do we mean when we speak of our senses? What are their use and what their capacities? It is difficult to define what we imply by the term sensation. Sensation appears to be a peculiar modification of consciousness developed by the action of external stimuli on certain special organs called sense organs, by which the nature of sensible objects is made known to us. The senses, as commonly enumerated, are five in number—those of sight, hearing, smell, taste, and touch. For the proper use of these senses we require a special terminal sense organ and a connecting link between the two. The terminal sense organ is that which directly receives the impressions, and varies in character according to the sense to be supplied, and the connecting link plays the purely mechanical part of conducting the impressions so received to the central sense organ or special part of the brain, to be there translated to the consciousness as sensations. There must also exist some stimulus external to ourselves to produce the impression on the terminal organ, and an unknown quantity, which we call the mind, which makes us conscious of the impressions on the brain. It is quite evident that all these factors are essential. Thus, if the eye be absent or the retina insensitive, there can be no consciousness of light; and if that part of the brain which responds to impressions on the ear be absent or imperfect, the sense of hearing is lost or modified. These factors are present in all animals which are possessed of senses; and just as man has the most highly-developed brain, so, for the requirements of his life, are his sensory organs correspondingly developed. It would be useless to him to be endowed with a brain capable of receiving and translating the most complex impressions, unless he possessed terminal organs equally capable of receiving such impressions, and however perfect and sensitive his sensory organs they would be of little use to a brain imperfectly developed.

It is impossible to classify the senses in any way that is strictly scientific; but the usual method is to class them under headings descriptive of the impressions produced on the mind through the medium of the different sense-organs. Thus we speak of the senses of sight, hearing, smell, taste, and touch; but it will be readily seen that the sense of touch is completely different and much more complex in character than the other senses; it is for this reason that the sense of touch is sometimes spoken of as a "common sense," and the other four as "special senses." Sensations depend on the nervous action excited, which, again, on its part depends largely on the manner in which the external impulse is applied. This holds good for all the senses; thus tone and colour depend on the rapidity of the impulses made on the auditory and ocular apparatus, and it is self-evident that the sense of touch varies considerably according to the stimulus applied. But there is this great distinction that, whereas stimuli applied to the nerves of a special sense give rise to a very limited range of sensations, those applied to the tactile organs excite a class of sensations which vary almost endlessly, according to the manner in which the impulses are applied. We know that, whatever the character of the stimulus applied to the ocular apparatus, the result is always the same—a sensation of light. The victim of a blow on the eye "sees stars." Again, rapid movements of the eyes and pressure on the eyeballs in a dark room produce the same sensation of light. Whether the stimulus be mechanical or spectral the result is identical. The same holds good for the auditory apparatus; whatever the stimulus the result is sound; the kind of sound may vary—it may be musical or discordant, it may be of high or of low pitch—but it is sound. We know that tinnitus aurium, or persistent subjective sound in the ears, is produced by stimulation of the auditory nerve or pressure on the labyrinthine nerve fibres in diseased conditions of the ear. With general sensibility, however, the case is different. We seem to have many senses bound up under the same term, some being modifications of each other, but others partaking more of a special nature; thus we have the sense of simple touch, the sense of locality, the temperature sense, the sense of pain, and the muscular sense. Some of these, I have said, are merely varieties or degrees of the same sense, and are produced by varying stimuli applied to the sensory nerves. As a familiar illustration of this fact I may point out that the schoolboy in handling the cane as a matter of curiosity is conscious of the sense of simple touch; but when the same cane is applied smartly to the fingers as a means of correction his sensations are fully represented by his cries.

There is another important distinction between the sense of touch and the other senses, and it is this—that while each of the latter is excited through a single organ, that of touch is excited by impressions applied to the whole surface of the body. It would manifestly be very inconvenient to us if the general surface of the body possessed the sense of sight—all that is necessary is that the special sense organ of vision should have a commanding but protected position. The same holds good for the other special senses, but not so with the sense of touch. That sense is given to us principally for our protection, and, this being so, it is necessary, in order that it should fulfil that purpose, that the general surface of the body should respond to the stimuli. Consequently we find that the skin is much more sensitive than the deeper structures of the body. A muscle when cut is almost insensitive unless a sensory nerve is injured. Every surgeon knows that the most painful part of an operation is in the initial stage, when the skin is being divided, and that when he gets to the deeper structures of the body, unless diseased, they are almost insensitive. Again, the water which scalds the lips and mouth when it reaches the stomach is only

Digitized by Google

able to give us a slight sensation of pain. Thus we see that though all the senses are alike in their physiological requirements, the nature and distribution of the sense of touch is widely different from that of the other senses. Now, in ordinary language we speak of our different sensations as though perceived by the organ which receives the impressions; we say that the eye sees, the ear hears, and the tongue tastes; this is a convenient and even necessary method of expressing ourselves, but scientifically it is inaccurate. It is the brain which alone has the power of perception; the eye does not see, nor the ear hear, neither does the tongue taste, but the impressions received by these organs are conveyed to the brain and translated by the mind into sensations of colour, sound, &c.; the sensations are solely in the mind. So that as sensation is a quality of the mind, and not of the body, it is a mistake to speak of the different sensations, as we habitually do, as bodily sensations. Again, when we fix our attention on objects around us we commonly and most inaccurately speak of our perception of those objects through certain qualities. Thus we speak of the colour of flowers, the song of birds, and the taste of food, inferring that the object has that particular quality which it has not, for these qualities are our own mental sensations. More than 400 years B.C. Plato recognised this fact, and in his "Dialogue on the Republic" illustrates the nature of our sensuous knowledge through a parable. He supposes a number of captives confined in a cave and bound down in such a manner that they can only see the further end of their prison, and that across the mouth of the cave pass figures which cast their shadows within. The prisoners, only able to see the shadows, would speak of them as realities and invest them with names and qualities; so with us: the world is a mere world of sensations and shadows, quite as unlike the realities as Plato declared them to be.

It is difficult for us to conceive that we do not see things as they appear to us projected into space, but it is no longer capable of dispute that our ideas of size, space, and distance are the results of acquired knowledge founded on mental efforts and experiments principally made during the year of infancy. The man, who, blind from birth, is suddenly, by surgical operation, put in possession of the faculty of sight cannot distinguish distance by sight alone. All objects appear equally near to the eye, and objects known to the touch are not recognised by the eye until the person becomes accustomed to compare his sensations of touch with those of vision; he cannot even distinguish a body in action from a body at rest—that is, he does not conceive that successive impressions of the object over the field of the retina imply that it is moving. Though this is so, though we are perfectly aware that nothing outside ourselves possesses the qualities that we invest it with, still we find it convenient to ignore the fact and to speak of the brilliant sunshine, the green grass, the disagreeable smell, and so on—it is our only method of expressing ourselves. If it be true, then, as I have just stated, that all sensations take place in the brain, how comes it that we refer these sensations to objects outside ourselves? The answer is, By experience. The newly born child has no knowledge of the external world, and his range of sensations is very limited; he recognises the sensation of light and moves his eyes towards the source of the impression, and, as he grows older, he learns to associate involuntarily the movements of the eye necessary for the fixation of the object. At the same time, the sense of touch being very early developed, he touches the object, recognises its presence, and learns the requisite muscular effort required to bring the hand into contact with it. Not only this, but he sees his hand, he sees its movements, and he sees it touch the object. By comparing these impressions of sight, touch, and muscular movement he elaborates, by slow degrees, the ideas of substance, of resistance, and of extension, and attaches physical qualities to certain objects. These different sensations combine to teach him that the object which is giving rise to varying sensations of the mind is external to himself, he begins to be conscious of something outside the *ego*—conscious of the world around him. If he were only to recognise the mental impressions, he would have to particularise each separate impression producing sensations of light, feeling, muscular sense and movement, but he only recognises one impression—namely, the object that he is seeing and touching: therefore it must be outside himself. As he increases in physical and mental development the child learns to refer all his sensations to external objects, and to think of them as directly giving rise to those sensations.

In fact, all our knowledge of the world around us, our knowledge of everything that exists, our whole power of reasoning, is dependent on the exercise of our senses; without his senses man would be merely a potential being. Kant puts the same thing tersely and epigrammatically. "Concepts without intuitions," he says, "are empty; intuitions without concepts are blind"; that is to say, "Without our senses our mind would be empty, without our mind our senses would be blind." In these few words is bound up the whole philosophy of the subject. It does not seem, however, that all, or nearly all, the senses are necessary for the full development of the brain. We are aware of many cases which prove the contrary—men and women who, deprived of one or more senses from birth or early childhood, have been found capable of fulfilling important duties in every walk of life; their conception of the world around them must be very different to ours, but what they lose from defect of one sense is made up to them by hypersensitiveness of others. John Stanley, the eminent musician, born in 1713, lost his sight at the age of two years. For fifty years of his life he held the appointment of organist both of the Temple Church and of St. Andrew's, Holborn; he was an expert performer on the flute and the violin, and for ten years superintended the performance of the oratorios at Covent Garden Theatre. Stanley's skill as a musician was such that, when at a performance of one of Handel's *Te Deums* he found the organ a semitone higher than the other instruments, he without any premeditation transposed the whole piece from D into the key of seven sharps major. To take another striking instance of what the capacities of a blind man are, I may mention the case of John Metcalf, the greatest blind mechanic who ever lived, who, born in the year 1717, at the age of six became totally blind from small-pox. In the words of Mr. Hanks Levy, himself a blind man, speaking of Metcalf, he says: "He walked and rode, he swam, fished, played at cards and skittles, rode and betted on races, was an excellent performer on the hautboy and other instruments, was a very successful recruiting agent, and as a soldier was the life of the corps to which he belonged. He was a dealer in horses, fish, hay, and wood, and succeeded in evading the law in various contraband transactions. He was successful in building houses and in making a great number of roads and bridges which to this day are a lasting memorial to the genius, perseverance, and indomitable courage of this blind man." In our own days we have had John Fawcett, Postmaster-General and Cabinet Minister, one who through his great mental qualities and sound common sense was a mainstay to his party. All these are instances of what can be done in spite of the loss of a single sense. But let us go further. We have all heard of that wonderful American woman, Laura Bridgman, born in 1829. At two years of age, when she had only mastered the difference between A and B, she became seriously ill, and when she recovered, five months later, she was blind, deaf, and had nearly lost the power of smell and taste. Her sense of touch, however, was perfect, and through this one sense she was taught to read by several systems; she was taught to write, and, most wonderful of all, communicate with her fellow-creatures. Laura Bridgman possessed a master-mind; no difficulties were too great for her, and she died at an early age, justly celebrated as a teacher and an author. The case of Helen Keller is, perhaps, the most wonderful of all. Born in 1880, she became deaf, dumb, and blind at the age of eighteen months. When seven years of age she was placed under the instruction of an expert, who taught her entirely through the sense of touch. In a few days she had mastered the manual alphabet and was learning the names of objects around her, and within four months of the beginning of her education she was able to write a perfectly legible and correctly spelled letter. At the age of ten she learned to speak, being taught to imitate the movements of the lips, tongue, and throat in her instructor by touching them with her fingers. In twenty-four days she had the free use of speech. In her case, as in that of Laura Bridgman, her education was effected through the sense of touch; if she had been without that sense, her brain would have remained dormant—capable, it is true, of great things, but undeveloped because incapable of receiving intelligence of anything outside itself.

Before leaving this part of my subject let me say a few words on the subject of the unrecognised sense.

Digitized by Google

Just as mathematicians are fond of speculating about a fourth dimension, so do physiologists try to prove the existence of a sixth sense. I have personally no doubt—and no one who has much to do with them can fail to recognise it—that the blind possess a sense which is either absent or lying dormant in the sighted. A blind man who has been properly educated will walk along a crowded street, cross roads, and run up and down staircases with the greatest facility. I have seen dozens of blind men skating together and never coming into collision, which is more than can be said for their sighted brethren. A blind man when opposite an object can perceive whether it be tall or short, slender or bulky; he can detect a solitary object or a continuous fence. Mr. Hanks Levy says that he can do all this and more; when walking along a street he can distinguish shops from private houses, and even point out the doors and windows. He says that darkness makes no difference to him, but that a fog dulls his powers; that he seems to perceive objects through the skin of the face and to have the impressions immediately transmitted to the brain. Covering his face with a thick veil destroys the sense altogether. He calls this unrecognised sense by the name of "facial perception."

Now it is quite evident that just as our mental powers can be developed by education so also can our senses. The newly-born child is conscious of the stimulus produced by light, but he has no impression of objects, he has no peripheral vision. His sense of touch is strongly developed from birth, but he is without the sense of hearing till the second or third day, and possibly later. As the child grows up his senses become more developed and his intelligence increases; so it is with all of us: our senses and our intelligence go hand in hand and increase in powers of perception and conception until with advancing age they again become blunted. Some are, no doubt, endowed by nature with greater quickness of observation than others, but all can cultivate the powers they possess. About the middle of this century there appeared in London a Frenchman named Houdin, who had cultivated his powers of quick and accurate observation to a degree of perception that was hardly short of miraculous. His father had been in the habit of training his perceptive faculties from early youth by making his son walk down a street and then describe all that he had seen in the windows of the shops he had passed. Taking advantage of his exceptional quickness, the father professed that his son was gifted with second sight and made a handsome income by exhibiting his powers. One of his favourite tricks was to hold a *séance* in the drawing-room of a strange house and to make his son give a description of one of the rooms on the ground floor, which room he had previously allowed him to glance into on his way through the hall. Houdin would accurately describe not only the furniture and ornaments of the room, but also the subjects of the pictures and the names of the books in the bookcase—all his information being obtained by one quick glance. The painter in the study of his art learns to distinguish gradations of colour too subtle for the uneducated eye to perceive. He can resolve colours into their component parts, and when he wishes to reproduce the beauties of nature on his canvas he uses a number of pigments which to the uninitiated bear no relation to the general scheme of colour. The musician, by long practice, can recognise the fundamental and overtones of every note; he can pick out the individual part in a complicated piece of orchestral work, and a false note made by a single instrument is immediately detected. The wine-taster is, by long experience, able to value the different kinds of wine, either through the sense of taste or smell. So it is with the medical man, who is enabled to detect the slightest departure from the standard of health with a precision only born of constant practice and observation. The whole art of diagnosis, all success in treatment, depends on an intelligent use of our senses. Everything we know in medicine and surgery has been learned through the senses, and the greatest discoveries have been made by means of discriminate observation. The medical and scientific world is at the present moment mourning the loss of one of the greatest savants and experimenters of modern times; one who, by his genius, became pre-eminent as a chemist; one who saved for his fellow-countrymen untold wealth, and who paved the way for the successful application of preventive treatment in medicine. I speak, of course, of Monsieur Pasteur, who, living to an advanced age, never seemed to tire of the *rôle* of benefactor to his fellow creatures. How was it done? By the constant and untiring use of the senses, by trained observation, and by well-ordered experiments. We cannot begin too soon in our medical education to cultivate those senses which are to assist us so much in our profession. Anatomy was never learned by reading books; the only true way to study anatomy is by dissecting and seeing for oneself the complex arrangement of the human frame. Learnt in this way it is never, it can never, be forgotten. It was while dissecting as a student that Sir James Paget discovered the presence of the trichina spiralis in the diseased condition called trichiasis. And whilst I am on the subject of anatomy let me impress on you one thing, and that is to feel everything with your fingers as well as seeing it. Holden says that every surgeon should have eyes at the end of his fingers, so as to form a mental picture of what he feels, and every surgeon knows that when operating he has often to be guided by his fingers where, owing to bleeding or position, he cannot see. But unless he has learned by experience to recognise what he feels his fingers will be of no use to him. So I cannot impress on you too strongly the importance of accustoming your fingers to the feeling of the normal parts and their relation to each other, and this experience you can gain in the dissecting room with very little trouble. Just as anatomy and physiology, chemistry and materia medica, and all those subjects which will take up your attention during the first two years of your studies—I say, just as these subjects lead you onward to the study of the greater sciences of medicine and surgery, so the habits of observation that you have acquired while mastering them become of infinite value to you when face to face with disease in the wards or the dispensary. Here, again, your efforts to acquire a habit of quick observation should be unceasing—eye, ear, touch, all the senses should be brought into play, first consciously, but with practice almost unconsciously. You may think that I am laying an unnecessary amount of stress on this point, but I assure you it is not so. From my own experience I find that a very large proportion of students notice nothing about their patients until they begin to interrogate them and to find out the history of their complaint. The patient possibly is lame, or his fingers are disfigured with rheumatic gout, or one of his eyes may be injured, but the unobservant student has seen nothing; not so with the practised observer, who takes immediate note of any peculiarity of gait, posture, or figure, who hears the cough and notes its character, and takes in, almost insensibly, the nature and characteristics of his patient before asking him a single question. In diagnosis there are two methods of procedure usually followed; on is to take note of all the physical signs and symptoms of the patient, and afterwards to elucidate the history of the case, and the other method is to reverse the process and begin with the history. The latter is the more generally adopted as it is the easier, for the more salient features of the disease may often be discovered through the history without the trouble of any further examination; but whichever method is carried out it is wise to begin by taking a rapid and comprehensive survey of your patient before doing anything else, for it is in the first few seconds that you will notice most. But let me warn you, on the other hand, against the evils of "snap-shot diagnosis" which we are all of us so prone to in the earlier part of our career. These rapid observations of the outstanding features of a case should not be made the basis of an immediate diagnosis, but should rather act as guides to our subsequent examination, both physical and historical, of the condition of the sufferer.

Let me give you a few instances of what I mean. The man whose jaw is broken supports his chin on his hand; when the clavicle is fractured the shoulder on that side is flattened and drawn forwards and inwards, and the elbow is supported by the opposite hand to take off the weight. The peculiar swaying gait, the body being poised over each limb in turn at every step, betrays the condition called congenital dislocation of the hip, and the position of the limb makes us suspect the presence of hip disease in its early stage, the joint being flexed, abducted, and rotated outwards into the position of greatest ease. A person suffering from inability to face the light, with watering of the eyes, compels us to think of disease of the cornea; but if these symptoms are confined to one eye we suspect the presence of a foreign body or some local cause of irritation. The ataxic patient walks into the room with exaggerated movement of the legs, but he who is suffering from lateral sclerosis drags his stiffened limbs behind him. The complexion and appearance of the face may help us in many

ways—it may be anæmic, chlorotic, flushed, cyanotic, or jaundiced; it may be emaciated, puffed, or œdematous. These are only a few illustrations amongst a host that crowd into one's mind. Numberless instances might be quoted to illustrate the value of the cultivation of the senses in the practice of our profession. Take the case of tumours. The uneducated eye sees a swelling of a certain size and shape and nothing more; but the surgeon has to learn the nature of the swelling—he looks at the skin over it and at the vessels transversing its surface; he notes its colour and the presence of inflammation or ulceration; his fingers detect whether the skin over the tumours is loose or bound down, whether there is fluid inside it, or, if solid, what its consistence; the hand applied to the surface detects increase of temperature or presence of pulsation, and the ear or stethoscope hears the bruit or sound within. All these points and more must be gone into before a satisfactory diagnosis can be made.

Even the most highly trained senses may be mistaken, and it should not be forgotten that a single sense may be wrong in its deduction, but that where several senses point to the same conclusion the evidence is much strengthened. We have all heard, and some of us may have had experience, of illusions of the senses, but we know that it is always a single sense that has been led astray; the ghost is seen gliding through the corridor, but there is no sound or footfall; the carriage is heard to drive up to the door, but no horses can be seen. An illusion never affects more than one sense at the same moment. Again, to take other instances, the educated fingers can detect the slightest deviation from the normal standard in the tension of the eyeball. The operator, by his cultivated sense of touch and exact balance of muscular action, is enabled to perform difficult and dangerous operations with comparative ease and safety. To such a pitch of perfection can this "tactus eruditus," or educated sense of touch, be brought that the surgeon, in passing the catheter or the lacrymal probe, can tell immediately if the point of his instrument is following a wrong direction, and is informed of the character of the mucous surface his instrument is traversing. I was told lately of a well-known surgeon who was exploring an incised kidney through a lumbar incision in order to discover the presence of a stone. With the point of his finger he was able to find it; and not only so, but he gave an elaborate description of the stone, its size, shape, and character, so graphic and so precise that his auditor could have drawn an exact representation of the calculus before he saw it.

Again, what should we know of the condition of the internal organs if it were not for our educated senses? Take the case of the chest—with the ear and the stethoscope we listen to the sound of the heart and discover the presence, character, and position of murmurs or periodical sounds; we listen to the lungs and notice the respiratory and pleural sounds and the vocal resonance. Inspection, auscultation, palpitation, and percussion all give their quotum of information. And so on through the whole range of medicine and surgery. It is quite evident then that you cannot bring yourself too much in contact with patients and their diseases, and it is for this reason that you are much to be congratulated on the wealth of material ready to your hand. Here you will have no excuse for not cultivating those senses which in some other schools might become blunted for want of use. And let me strongly advise you not to depend on what your teachers tell you, but to depend on your own observation; during the next few years you will be under the guidance of many instructors, but all they can do for you is to teach you how to learn for yourselves; your teachers as well as yourselves are merely students, only a few rungs higher up the long ladder of knowledge; they are all liable to error, and it should be your constant care to correct such error by the constant use of your own observation. I do not ask any one of you to become a Sherlock Holmes; that most interesting person, who died in this country in the early spring, but seems to have come to life again in America, had a comparatively simple task before him; from an accomplished fact he had to trace back the sequence of events until by discovering the why and the wherefore he was able to put his finger on the perpetrator of the deed. We have a much harder task, for we must look forwards as well as backwards; not only must we find the first causes and trace the origin and course of a disease, but we must also discover the indications which point to its future progress either for good or bad. But it is not sufficient to haunt the wards and dispensaries. We have seen already that sensation is a mental quality; consequently the brain must be educated. It is not sufficient for the brain to be a simple storehouse of impulses received through the senses; it must also be educated in order to give these sensations their proper proportion and significance. Reading, and wide reading, must be resorted to, to develop the mind and give it a broad grasp of the facts and realities of life. It is not by the exclusive use of the senses or by reading only that the highest development of reason is obtained, but by a proper combination of the two.

And now, gentlemen, a few words to those who are just beginning their professional career. You have probably studied your college calendar and have mystified yourselves to some extent with numberless details of what is about to be required of you. You have grasped the one outstanding and appalling fact that many examinations have to be passed before you can enter the portals of the medical profession. The terrors of these examinations have probably been enhanced by your friends—by those who have failed, because they wish to impress on you an explanation for their failure, and equally by those who have passed, who are anxious that you should realise the value of their achievements. You have very likely been told that for the next five years your life will be made a burden to you by their constant ordeals, and if that were in reality all you had to look forward to your existence would indeed be insupportable. But it is not so; and I implore you to remember from the first, from the very commencement of your professional studies, that the aim and object of those studies is not primarily or to any important degree to enable you to pass certain examinations, but that their object is to teach you your work, and to train you in the duties of your profession. A man who knows his work will certainly pass his examinations; but, on the other hand, many men have passed successfully only to find out afterwards that they did not know their work, and that their best opportunities for real study had passed away. The best advice I can give you is to put all thought of examinations out of your minds, to do the work that your teachers direct you to do, and to do it thoroughly, and when the time comes for the final effort, when each man strains every nerve to collect all his knowledge in a concrete form, you will find what a comparatively easy task you have before you, and examinations will lose their terrors. Work for the sake of the work itself, and it will well repay you. Some men work to make a living, some for ambition's sake, and some for the pure love of doing good to their fellow-creatures. Now I presume that most of us take up the medical profession with the object of making a living, and a very good object it is, too. I am not going to pretend to you that our one and only stimulus is the opportunity presented to us through our profession of doing good: you all know that it is not so; you have decided to join the ranks of the medical profession in order to make your way in the world. This is your primary object, but to it is added the great pleasure of knowing that inseparably bound up in the practice of that profession is the fact that we are benefiting mankind. What a stimulus should this be to us to make our work as perfect as we can, not only during our student days, but through the whole of our career.

A NATIONAL SYSTEM OF NOTIFICATION AND REGISTRATION OF SICKNESS.[1]

BY ARTHUR NEWSHOLME, M.D. LOND.,
MEDICAL OFFICER OF HEALTH OF BRIGHTON.

THE subject of this paper is not novel. Most of the proposals and suggestions which I shall make have been already made, more ably than I can hope to repeat them; and what is novel in my remarks is but the natural outcome of the pioneer advocacy by B. W. Richardson, Farr, Rumsey, Ransome, and many others. The present time, however, seems opportune to reopen the question, review the progress already made, compare our experience and present condition as regards the notification of sickness with that of other countries, and indicate the directions in which reform and advance are urgently required and may be most

[1] Abstract of a paper read before the Royal Statistical Society on Dec. 17th, 1895, Mr. C. S. Loch, B.A., Vice-President, being in the chair.

advantageously pursued. I shall in the first place briefly sketch the history of the question and the progress already made; this progress will in the next place be contrasted with that made in some other European countries; and, finally, proposals for further progress will be made.

The office of Registrar-General of Births, Deaths, and Marriages in England was created in 1836. The first report of the Registrar-General was published in 1839. Although the comparison of death-rates of great towns with each other, particularly for short periods, is fraught with fallacies, the general result of the publicity secured and of the consequent efforts on the part of local authorities has been an immense improvement in the public health of the community. The reduction in the general death-rate from 24·7 in town districts in 1851–60 to 20·2 in 1884–93, and from 19·9 in country districts in 1851–60 to 17·5 in 1884–93, and the reduction of the death-rate from "fever" from 792 per million in 1858–60 to 202 per million in 1886–90, are sufficient evidence of this. It soon, however, became evident that registration of deaths gave a very imperfect view of the prevalence of disease. It is very fallacious to assume any fixed ratio between sickness and mortality. The fatality of infectious diseases, for instance, varies greatly in different outbreaks under varying circumstances and in different localities. Thus, if it be required to compare the amount of scarlet fever in Brighton with that in London, in 1894 the death-rate from this disease in London was 0·22 and the number of cases was 4·24 per 1000 of the population. In Brighton in the same year the corresponding death-rate was 0·03 and the case-rate 1·85 per 1000 of the population. It can easily be calculated from these data that the ratio of the scarlet fever death-rate in Brighton and London was as 1 : 7·3, while the ratio of the corresponding case-rate was as 1 : 2·2. Thus the fatality of scarlet fever in Brighton was 1 in 62 cases, while that in London was 1 in 19 cases. Hence, while the deaths from scarlet fever in London were over seven times as numerous (in proportion to population) as those in Brighton, the cases were only about twice as numerous. This illustration serves to show that *mortality* is not necessarily a correct index of the *morbidity* of a community. The highest ratio of sickness is occasionally found associated with a favourable rate of mortality. Mortality statistics necessarily ignore everything that precedes the close of life. They are silent about the large mass of common sickness, which, although it may disable a man, is not "unto death." From the standpoint of the commonwealth and the common health, sickness is more important than death; for "it is the amount and duration of sickness rather than the mortality that tell on the prosperity of a community." (Dr. Dickson.) Or, as Charles Dickens has stated it: "It concerns a man more to know the risk of the fifty illnesses that may throw him on his back than the possible date of the one death that must come. We must have a list of killed *and of the wounded too*."[2]

[Dr. Newsholme then proceeded to give the history of attempts to establish registration of sickness. He said:]

Dr. Rumsey[3] in 1875 mentioned that it was one of "twelve proposals by which the lives of many thousands of the rich as well as the poor may be saved yearly," made to Parliament by Mr. John Bellers at the beginning of the eighteenth century, before the first of our modern hospitals was planned. It was again urged by Dr. Clifton, physician to the Prince of Wales in 1732, with special references to hospitals. Dr. Rumsey in 1844, in his evidence before the Medical Poor Relief Committee of the House of Commons, suggested a comprehensive plan for the uniform registration of the sickness which affects the poorer classes. In 1848 Dr. Liddle, subsequently medical officer of health of Whitechapel, proposed amended forms for the weekly medical returns made by their medical officers to boards of guardians, and the utilisation of these returns in general sanitary inquiries. About the same time it was suggested in the *Sanitary Review*[4] that there should be appointed a Registrar-General of *Diseases* in London as the central authority, to whom the district returns, after local use, should be forwarded for digest and publication. Dr. B. W. Richardson was, I believe, the first to carry any scheme for notification and registration of sickness into actual practice. The cases notified were tabulated in the *Journal of Public Health and Sanitary Review* of 1855; but he had written on the subject as far back as 1852. The registration was continued by Dr. Richardson for several years, "and in the end had observers, from Dr. Moyle of the Scilly Islands to Dr. Spence of Lerwick, in the Shetlands. At one time he had forty-four observers from latitude 40° 50′ N. to 60° 9′ N., and from longitude 6° 24′ W. to 1° 8′ W. These observers were all admirable men, and many of their local reports were most valuable, although now forgotten. They entered their remarks on printed forms, which were regularly posted to them each quarter." In the end, attempts to secure official support for the work having failed, the notification ceased. Dr. Richardson's personal pioneer effort to secure information as to sickness from different sources was soon followed by the Metropolitan Association of Health Officers, which in 1857 organised a combined effort to give authentic information concerning sickness of all kinds attended at the public expense. The returns included sickness of all kinds attended at the public expense, in hospitals and dispensaries, and by Poor-law medical officers, whether outdoor cases or in workhouses and infirmaries. The returns were contributed voluntarily and gratuitously by the respective medical officers of these institutions and the Poor-law medical officers. The General Board of Health undertook to print and circulate the weekly and quarterly tables; and meteorological tables were appended to each publication. This magnificent voluntary effort for some time appeared likely to prosper. At the most successful period, however, rarely more than 50 of the 109 metropolitan hospitals and dispensaries contributed to the returns. The returns of Poor-law cases were, at the best, from only 80 of the 180 Poor-law medical officers in the metropolis; and the official publication collapsed in November, 1858, before the end of its second year of publication. A much more successful attempt was organised in 1860 by the Sanitary Association of Manchester and Salford, Dr. Arthur Ransome being the moving central spirit in it. The tables compiled by this association had one special merit not shared by those of the Metropolitan Association: the number of deaths among the cases reported was stated, so that a complete comparison between the sickness and mortality in the groups and classes of population included in the reports could be made. The returns seem to have been conscientiously and completely made, thus giving them, as claimed by the honorary secretaries in 1862, "a value which no similar return has ever attained before." From this point the history of the attempt to establish registration of sickness is chiefly comprised in the proceedings of special committees of the Social Science and the British Medical Associations. At the Bradford meeting of the Social Science Association, in 1859, Dr. Rumsey read two papers bearing on the registration of sickness, and on the general working of the system of registration of deaths,[5] and, as the result of the discussion which followed, a committee was formed. This committee, in March, 1860, passed a resolution recommending, among other things, that the superintendence of the registration of births and deaths should be combined with that of sickness attended at the public expense, and, as far as possible, that of sickness attended at public institutions. This resolution was subsequently endorsed by the association and brought under the notice of the Home Office. At a meeting of the Lancashire and Cheshire Branch of the British Medical Association, held on Oct. 24th, 1862, it was resolved that a sub-committee be appointed "to consider and report on the best means of carrying out the registration of disease in large towns." A committee of the whole British Medical Association was appointed in 1865, at the instance of Dr. Ransome, and for ten subsequent years he prepared valuable reports, from which the following information is extracted. At a meeting of the British Medical Association held in Dublin on Aug. 9th, 1867, the form of return proposed by the above committee for the uniform registration of disease was adopted; and in January, 1868, the registration of disease occurring in public practice was commenced upon the same plan and with the same list of diseases at Manchester and Salford, St. Marylebone, Birmingham, Newcastle-upon-Tyne, and Gateshead. The returns were made monthly at St. Marylebone, weekly at the other places.

In 1869 a deputation headed by Dr. B. W. Richardson waited upon the President of the Local Government Board, who expressed himself "heartily with the deputation in spirit." In 1870 a deputation of the British Medical Association waited on Mr. Goschen, who thought it desirable to

wait for the report of the Royal Sanitary Commission. He agreed that the registration of disease would be an excellent thing. The report of the Sanitary Commission appeared in 1871, but nothing came of it.

One by one the towns contributing to the voluntary notification of sickness ceased their work, the efforts of Manchester and Salford being the most protracted and successful. It need cause no surprise that the voluntary coöperative principle has failed in this instance, notwithstanding the pertinacity and enthusiasm of its earlier advocates. "The voluntary principle, so powerful in the diffusion of Christianity, in works of mercy, in struggles for liberty, and in scientific discovery, has invariably proved quite unequal to the regular, constant, and universal performance of laborious official duties without any hope of profit or of praise." (Rumsey.)

The subject of a national system of registration of disease, the attempts to establish which I have sketched, appears to have gradually dropped into abeyance. It was blessed by medical men and sanitarians and Secretaries of State, and yet the inertia of officialdom appears to have prevented any practical steps being taken. The measure was not one which it was profitable to pursue in the stress of political party strife, and it was pushed aside for more urgent and politically more attractive schemes.

[Dr. Newsholme then passed on to consider the compulsory notification of disease:]

In September, 1877, the first local Act for enforcing the compulsory notification of the chief infectious diseases came into operation in Bolton, Lancashire. This example was followed by other towns, and the adoptive enactment of the Infectious Disease (Notification) Act in 1889 was followed by a rapid adoption of the Act by urban and rural sanitary authorities throughout England. At the present time the Act applies to five-sixths of the English population, and there is little doubt that it will shortly be made compulsory through the whole of Great Britain. Notification is but a means to an end. If the early and authentic information imparted to health officers by notification is simply filed in the office, the course of an epidemic will obviously be undisturbed; but when such notifications are followed by conscientious investigation, when the water-supply, the milk-supply, the school attendance, and a number of other factors in connexion with a series of cases of infectious diseases are examined, it is evident that the resulting chain of evidence may be, as in many instances it has been, so strong as to lead to immediate preventive measures of a most successful character, and in other instances to force the most radical reforms upon even unwilling sanitary authorities. This does not exhaust the benefit derived from compulsory notification of infectious diseases: the notifications have forced upon sanitary authorities the knowledge that there are infectious diseases in their midst, and the constant reiteration of the lesson has gradually and increasingly braced them up to the discharge of their duties. Hence it is not surprising to find that at no previous period of the sanitary history of England has there been such great activity as since 1889 in the provision of isolation hospitals. Even if these isolation hospitals have not, by the removal of first cases of infectious diseases in houses, diminished the prevalence of infectious diseases, they have as humanitarian institutions justified their existence by the better and more successful treatment that the majority of patients thus removed have secured; but they have also diminished the actual amount of some of these diseases. Small-pox epidemics are more easily manageable and have been kept within narrower bounds in communities in which all cases are notified and isolation enforced. Scarlet fever has declined enormously in mortality in recent years. Some of this decline is doubtless due to the milder type of disease now prevalent, the case mortality having become greatly reduced. It may be fairly argued, however, that the diminishing malignancy of this disease is partially due to the fact that cases of it, instead of being treated in crowded houses with imperfect nursing, are now treated in large airy wards, the virus of the disease not being concentrated by an unfavourable environment. This hospital treatment of infectious patients can only be secured in the majority of instances through the machinery of compulsory notification of the cases. Notification of infectious diseases, by forcing attention to them, has led to the provision of more efficient means of disinfection, to the removal of insanitary conditions to which in some instances they owe their existence, and to the steadily improving education of the public in hygienic matters.

[Dr. Newsholme then pointed out the various advantages gained from the mass of information accumulated through notification, and strongly urged the compulsory notification of *all* infectious diseases. He also suggested an interchange of information bearing upon infectious disease: (1) between different districts of this country, and (2) between this country and other countries. He continued:]

We may conveniently consider here foreign methods of notification and registration of sickness. A recent investigation into the etiology and relative prevalence of rheumatic fever in various parts of the world[6] has made me familiar with the available sources of information in many countries, and by personal inquiries in German and Scandinavian towns I have been able to acquire additional information from the responsible medical officers.

[Dr. Newsholme hereupon gave an account of the means adopted for the notification and registration of sickness in Belgium, Germany, Denmark, Sweden, and Norway, and after claiming that the scope of preventive medicine was co-extensive with all diseases, except the consequences of old age, concluded his paper with the following proposals:]

Accurate knowledge of sickness, of its degree of incidence in relation to sex, age, occupation, housing, locality—in fact, of all the conditions under which it is originated—must, however, precede rational preventive measures. Hence it is necessary that the following measures should be adopted:—

1. All cases of sickness occurring among the parochial poor in each district should be periodically reported to the medical officer of health, and tabulated statements concerning them forwarded to a central office in London, in which such statistics, along with those from other sources, should be analysed, summarised, and published. Schedules might easily be arranged similar to those in force in Christiania or Berlin, in which a weekly return of the new cases of sickness among the poor could be made by the Poor-law medical officer with a minimum of trouble. The cases in the workhouse infirmaries and in industrial schools should be similarly scheduled. Care would be required to prevent the same cases from being entered more than once. It may be mentioned that it has since 1879 been incumbent on all district and workhouse medical officers, and upon medical officers of district schools appointed since that date, to furnish the medical officers of health with returns of pauper sickness and deaths; but as the chief object of these returns appears to have been the notification of infectious diseases, the returns have been in most places allowed to lapse, and have not, I believe, been used for general statistical purposes.

2. All cases of sickness, whether out-patients or in-patients, at hospitals (general and special) and at public dispensaries should be reported weekly or monthly to the medical officer of health, and by him forwarded to the central office in London, to be there treated like the pauper statistics. The hospitals and dispensaries of this country are supported by subscriptions or bequests, and they owe it to the State to furnish the fullest particulars which the latter may require. Every public institution for the treatment of the sick should, I maintain, be required to give to the medical officer of health a weekly statement of the number of new in-patients and out-patients treated during the week, specifying the age and sex and nature of the illness of patients; also a quarterly or annual statement of the total cases, and the number of days spent by each patient in the hospital. The statistics of large general hospitals, especially those to which medical schools are attached, are of great value, the diagnosis and certification being exceptionally accurate. I have recently shown that the statistics of the chief metropolitan hospitals give a faithful index of the yearly incidence of rheumatic fever in London, and the same must be true for many other diseases. It will hardly be credited that several of the large metropolitan hospitals, as University College, London, and Guy's Hospitals, publish either very imperfect or no tabulated statistics of annual cases of sickness. At the Edinburgh Infirmary such records were only commenced in 1889, while in other hospitals in various parts of the country accurate statistics have been kept for a long series of years, as at Aberdeen, Glasgow, York, Bradford, Brighton, and many other places. It should be made obligatory on the managing bodies of all general and special hospitals and all public dispensaries to keep accurate entries of all cases treated at these institutions, and to report on special schedules these cases to the medical officer of health at stated intervals. What has been done in Germany can be done here, and as they followed our lead in respect of

[6] Milroy Lectures on the Natural History of Rheumatic Fever, 1895.

Digitized by Google

registration of deaths it is for us now to follow them in registration of hospital and other forms of sickness. The question of hospitals would not be complete without reference to the special hospitals now established in most towns and districts of England for the isolation and treatment of infectious diseases. Many important problems as to the intensity of different epidemics, the relative fatality of cases occurring in different districts, the influence of "hospitalism" on the character of each disease, &c., might be solved by accurate comparative statistics for the great fever hospitals throughout the country. At present there are statistical reports for such hospitals in the annual reports of some medical officers of health of very varying comprehensiveness and value. What is required is that these should be formed on a uniform basis, and that the statistics from different hospitals should be analysed and published at a central office in London. It is but fair to mention here the extremely valuable reports of the statistical committee of the Metropolitan Asylums Board. The year 1894 was the ninth year of issue of this report, which is in some respects a model for others. I may also mention here the statistics in the same report as to lunacy and imbecility in the asylums and schools of the Board, which it ought to be practicable to compare with those of other similar establishments throughout the country. The lunatic asylums for each county form another field for collective investigation, which can only be fully utilised by analysis and tabulation of statistics at a central office.

3. All friendly societies and all sickness insurance societies of every description should be required to furnish weekly or monthly returns of the number of new cases of sickness in their experience, classified according to a specified schedule, and a yearly statement of the total subscribing number of members, classified according to age.

4. An attempt should be made to obtain accurate returns of sickness in the great industries. This can only be gradually secured. Two factors are necessary in order that industrial sickness may be estimated for comparative purposes: (*a*) an accurate return of the number of men employed in each industry; and (*b*) a similarly accurate return of the cases and causes of sickness, each classified according to age. Some important steps have been taken in this direction in the Factory and Workshop Act, 1895, which will come into operation on Jan. 1st of next year. By Section 34 it is required that:

> The occupier of every factory and workshop shall, on or before the 1st day of March in every year, send to the inspector of the district on behalf of the Secretary of State a correct return specifying, with respect to the year ending on the preceding 31st day of December, the number of persons employed in the factory or workshop, with such particulars as to the age and sex of the persons employed as the Secretary of State may direct, and in default of complying with this section shall be liable to a fine not exceeding £10.

There is, however, no provision requiring a general notification of sickness among the employés, although this would be quite practicable. The only approach to it are the enactments contained in Sections 20 and 29. Section 20 states that:

> 1. Every occupier of a factory or workshop shall keep a register of accidents, and shall enter therein every accident occurring in the factory or workshop of which notice is required by the Factory Acts, within one week after the occurrence of the accident, and this register shall be at all times open to inspection by the inspector and the certifying surgeon for the district.
> 2. If any occupier of a factory or workshop makes default in complying with the requirements of this section, he shall be liable on summary conviction to a penalty not exceeding £10.

This enactment will doubtless be of great value in determining the relative liability to accidents of different industries, and the directions in which additional regulations and restrictions are required. Section 29 requires that:

> 1. Every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from lead, phosphorus, or arsenical poisoning, or anthrax, contracted in any factory or workshop, shall (unless the notice required by this section has been previously sent) send to the Chief Inspector of Factories at the Home Office, London, a notice stating the name and full postal address of the patient, and the disease from which, in the opinion of the medical practitioner, the patient is suffering; and shall be entitled in respect of every notice sent in pursuance of this section to a fee of 2*s.* 6*d.*, to be paid as part of the expenses incurred by the Secretary of State in the execution of the principal Act.
> 2. If any medical practitioner, when required by this section to send a notice, fails forthwith to send the same, he shall be liable to a fine not exceeding 40*s.*
> 3. Written notice of every case of lead, phosphorus, or arsenical poisoning, or anthrax, occurring in a factory or workshop, shall forthwith be sent to the inspector and to the certifying surgeon for the district; and the provisions of the Factory Acts with respect to accidents shall apply to any such case in like manner as to any such accident as in those sections mentioned.
> 4. The Secretary of State may by order made in accordance with Section 65 of the principal Act apply the provisions of this section to any other disease occurring in a factory or a workshop, and thereupon this section and the provisions referred to therein shall apply accordingly.

While in full sympathy with the object in view in Section 29 of the Factory and Workshop Act, 1895, an earnest and emphatic protest must be urged against the machinery and the destination of the notifications proposed in this section. As I have elsewhere stated,[7] it constitutes a new departure, that of compulsory notification of disease by a medical practitioner to a layman. It involves a most pernicious procedure, one not only fraught with serious direct and indirect detriment to the medical profession, but also detrimental to the object in view, as it involves, in some degree at least, the investigation of the causation of special diseases—a medical problem—by lay inspectors. The medical officer of health is in virtue of his special training and profession the person to whom these diseases should be primarily notified, and who should guide the remedial measures to be taken. In a letter[8] Dr. Russell, the distinguished medical officer of health of Glasgow, after referring to and endorsing the above-quoted remarks, states: "Apart from the principle, the method of this Act is absurd." He then quotes the following paragraph from a statement submitted (unsuccessfully) to Mr. Asquith by the Police Commissioners of Glasgow during the committee stage of the Factory and Workshop Bill, 1895: "The medical practitioner will form an opinion that his patient suffers from poisoning or anthrax before he arrives at any conclusion as to its cause. This presumes an inquiry into circumstances, and the conclusion may possibly not be one which will make the practitioner any more popular in the locality if he promulgates it. Let every such case be notifiable to the medical officer of health of the district as if it was an infectious disease. Let the medical officer of health make the inquiry, and if he believes the disease was 'contracted in any factory or workshop,' let him at once inform the local factory inspector."

I will now sum up. What is advocated is that:

1. All cases of sickness treated at the expense of public funds, whether in connexion with the administration of the Poor-law (out-door infirmaries, industrial schools, &c.) or in isolation hospitals, or in idiot and lunatic asylums, should be periodically notified to the medical officer of health.

2. All cases of sickness treated by means of public charity, whether in general or special hospitals, or dispensaries, should be similarly notified.

3. All cases of sickness treated in friendly societies or other sickness assurance societies should be similarly notified.

4. Returns of accidents and of certain diseases, as lead poisoning, woolsorters' disease, &c., or other industrial diseases, should be made part of a wider system of notification of diseases by private medical practitioners to the medical officer of health of each district.

5. The schedule of notifiable diseases under the Infectious Diseases (Notification) Act should be widely extended. Diseases should be classified into those compulsorily notifiable (1) within twenty-four hours, and (2) weekly, and the list of the latter should be greatly increased; they should include pneumonia, rheumatic fever, phthisis, and other diseases, as lead poisoning &c.

6. In connexion with this extension of notification the whole question of payment of fees for notifying will require complete reorganisation.

7. All notifications of sickness should be sent in the first instance to the medical officer of health of each district, and by him transmitted to a central office in London.

8. The central office in London should probably be in connexion with the General Register Office, Somerset House, and weekly returns of sickness should be published alongside of the weekly returns of mortality. The most urgent of these reforms is the collection and tabulation of the cases of sickness attended at the expense of the public funds or treated in public charitable institutions. This might be begun almost immediately. The only obstacles are the *vis inertiæ* of the responsible heads of Government departments and the expense that would be incurred. Successive Secretaries of State have committed themselves to the principle of the proposal, and there is reason to hope that strenuous action and agitation on behalf of this proposal by the Royal Statistical and other allied societies would secure the desired end. I can conceive of no work more important in conducing to the

Digitized by Google

progress of both curative and preventive medicine than that which I have briefly described; it is a work of national importance, and the obtaining of this additional information for every district and town, with the present staff of medical officers of health eager to avail themselves of it, would undoubtedly be followed by marvellous improvements in the public health.

INTESTINAL OBSTRUCTION DUE TO FÆCAL ACCUMULATION ASSOCIATED WITH DISPLACED KIDNEY.

BY WALTER A. KIDD, M.D. LOND.,
LATE HOUSE PHYSICIAN, GUY'S HOSPITAL.

IN THE LANCET of July 21st, 1894, I described four cases in which the above connexion of events occurred, and since then I have met with three more cases in nearly all respects similar.

CASE 1.—The patient was a woman aged sixty years, multipara, thin, active, healthy, neurotic, and subject to constipation, but not in the habit of taking aperients. I was called to see her as she was suffering from acute abdominal pain, which came on after an indigestible meal. The pain was referred to the region of the transverse colon and the back. Vomiting occurred, but did not relieve the pain. An aperient medicine which she had taken failed to evacuate the bowels. I found a large oval swelling with smooth outline occupying the right hypogastric and iliac region, decidedly tender on pressure. Under the influence of opiates and fomentations and starvation the pain subsided in two days, and the bowels acted copiously by the help of enemata. As the patient recovered the swelling diminished considerably, and she was found to have a displaced, slightly movable, but not enlarged, right kidney. After a few months orders to attend to the evacuation of the bowels were neglected, and a similar but slighter attack occurred. On this occasion the accumulation in the colon was smaller, and, as the patient recovered, the kidney was found to be in the same condition and position as after the former attack. Constipation continues in this case and has to be treated by regular aperients.

CASE 2.—The patient was an unmarried woman aged forty-seven years, well-nourished, of neurotic type. When first seen by my partner, Dr. Mackern, in my absence, she was found to be suffering from general abdominal pain, which was largely pelvic. The abdomen was large and generally tender, a large mass being clearly felt in the right iliac region. A ring-pessary in a foul state and rough from wear, which she had worn on account of some uterine displacement, was removed, but no relief was given. It was ascertained that she had suffered from displacement of the right kidney before this illness. The pain now centred in the mass on the right side, and the temperature was raised from 100° to 101° F. and night perspirations occurred. By the action of opiates and laxatives the pain was reduced and the bowels evacuated, and after an illness of about ten days the patient was convalescent, and the right kidney was found to be displaced, somewhat enlarged, lying in the right iliac region, and the greater mass which had existed in that region had disappeared.

CASE 3.—The patient was a woman aged sixty-five years, multipara and very thin, with weak muscular system and highly neurotic. She had been subject for many years to irregularity of the action of the bowels, slightly to constipation, but more especially to recurrences of "diarrhœa" with lumpy stools. She had known of the existence for a long time of a painless lump in her right side about two inches from the umbilicus; this lump used to slip away from her hand as she felt it. Dr. Mackern saw this patient also in my absence, and found that for a few days prior to his visit the lump had become larger and more tender, and there had been a tendency to diarrhœa alternating with constipation and lumpy stools. There was little or no pain in this case. Aperients and olive oil brought away copious evacuations, with diminution in the size of the mass and relief of all discomfort. Abdominal massage and the regular use of cascara sagrada kept the bowels free, and it became clear that the fæcal accumulation had disappeared, and a movable right kidney, not tender, was left.

There are thus in these two series of cases—seven in all—with very similar symptoms, progress, and, I think, causation. Six had somewhat acute symptoms of obstruction, and the seventh a nearly painless attack of obstruction, with looseness of the bowels due to fæcal accumulation. All of the seven were in women, whose ages ranged from forty-two to seventy-two years. Four were multiparæ and three were spinsters. Out of the seven, four were decidedly subject to constipation, and the other three were not liable to any intestinal disorder other than attacks of abdominal pain or recurrences of so-called "diarrhœa." If, in these seven cases, the connexion between displacement of the right kidney and fæcal accumulation in the right half of the colon be one of cause and effect, there seems to be no reason why one should look for any influence other than a mechanical one. A very slight degree of pressure, especially of a kind which was not uniform, on the lumen of the large intestine would suffice to arrest partially the upward passage of its contents. No doubt in most cases of disturbance of the functions of the abdominal viscera the aid of the sympathetic nervous system may be called in for the purpose of explaining such disturbances, often wrongly. Here, as in many others, a simple anatomical explanation is forthcoming, and mechanical pressure may be set down as the efficient cause. But, seeing that the nerve-supply of the right half of the colon and that of the supra-renal body and kidney is derived from the outer side of the solar plexus, and that the nerves to the supra-renal body are large and directed horizontally outwards, it is not unreasonable to suppose that the alteration of the position of a displaced kidney may interfere with the nerves of the organ in a way which will communicate itself to an organ whose nerves arise from a neighbouring part of the great plexus, which presides over so many viscera. Whatever form the interference with the nervous apparatus of the colon should take, whether inhibition of its normal peristaltic action over several inches of its length, or over-stimulation of that peristaltic action, the ultimate result would probably be the same—viz., stasis of the contents of the ascending colon, or hepatic flexure of the colon. The fact that many displaced kidneys give rise to no symptoms does not disprove this suggestion as to a connexion through the renal and supra-renal plexuses and the superior mesenteric plexus, for many displaced kidneys are tender and somewhat enlarged for a short time only, and this tenderness is little recognised or attributed to its real cause, the influence through the nerve-relation only taking place during those periods of tenderness and enlargement. In this suggestion of a nervous disturbance, radiating from one viscus to another through the somewhat abused sympathetic nervous system, one may be following out a wrong as well as an unnecessary track, when mechanical pressure alone is to blame for the obstruction of the intestine. But whatever theory we may form as to the nature of the causation, the practical rule to be applied to such cases is clear—viz., that the patient be instructed to attend systematically to the action of the bowels as long as she or he lives.

Blackheath.

WORD-BLINDNESS AND VISUAL MEMORY.[1]

BY JAMES HINSHELWOOD, M.A., M.D. GLASG.,
ASSISTANT SURGEON TO THE GLASGOW EYE INFIRMARY; DISPENSARY PHYSICIAN TO THE WESTERN INFIRMARY, GLASGOW; ASSISTANT TO THE PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF GLASGOW.

THE subject of this paper is one to which there is but scanty reference in English medical literature. My attention was specially drawn to it on meeting with the very interesting case which forms the basis of this communication. After spending considerable time and labour in searching out similar cases scattered throughout French and German medical literature, it occurred to me that it might prove useful to others to focus the results of my studies and personal observations in a paper, especially since the subject, though one of intense interest both from a medical and a psychological point of view, has received but little attention in this country. The following is the history of my case of word-blindness.

A man aged fifty-eight years has always enjoyed good health with the exception of occasional attacks of bronchitis

[1] A paper read at a meeting of the Glasgow Medico-Chirurgical Society on Oct. 4th, 1895.

in winter. He is a teacher of French and German, and is a man of intelligence and education. Of recent years he has had a large amount of mental work, and before his present visual difficulties appeared he had considerable mental worry. He first came under my notice on Aug. 29th, 1894, and gave the following history. About one month previously he was greatly startled to find that one morning in his own house he could not read the French exercise which a pupil gave him to correct. On the previous day he had read and corrected the exercises just as usual. Greatly puzzled he went into an adjoining room, and having summoned his wife, he asked her if she could read the exercise. She read it without the slightest difficulty. He then took up a printed book to see if he could read it, and found that he could not read a single word. He remained in that condition until I saw him. On examining his visual acuity with the test types I found that he was unable to read even the largest letters of the test types. He informed me that he could see all the letters plainly and distinctly, but could not say what they were. He made the most absurd mistakes, and only very rarely, after guessing several times, did he hit upon the proper name of the letter. What attracted my special attention was the fact that he read at once the number standing at the top of each paragraph of the test types. I found on examining him further with figures that he did not experience the slightest difficulty in reading any number of figures quite fluently and without making any mistakes whatever. He could read figures printed on the same scale as Jaeger No. 1, the smallest of the test types, and from other tests it was evident that there was no lowering of his visual acuity. His inability to read was thus manifestly not due to any failure of visual power, but to a loss of the visual memory for letters. The page of a printed book appeared to him exactly as it appears to a person who has never learned to read. He sees each individual character distinctly enough, but the character is no longer a visual symbol, as he no longer remembers the special significance attached to it. His difficulty with written characters was equally well marked, and it was the same for Latin and Gothic characters. He is ignorant of music, and I therefore could not test his power of reading musical notes. To put it briefly, he had lost the visual memory of all the printed and written characters with which he was previously familiar. He could, however, write with perfect fluency and ease to dictation, although afterwards he could not read what he himself had written. No other mental defect could be ascertained on the most careful examination. He spoke as fluently as ever, nor had he since the beginning of his attack ever experienced the slightest difficulty as regards speech. His mental powers were as vigorous as ever, nor was there any defect of memory apart from the loss of memory for the visual symbols of language. I was struck with the fact that in trying to read he always carried the book well to the left hand, and could not see it at all when carried to the right. On examining his visual fields with the perimeter there was found loss of the right half of each visual field—i.e., he had right lateral homonymous hemianopsia. No other defect could be found, and the fundus of each eye was perfectly normal on ophthalmoscopic examination. His general health was good, and with the exception of atheromatous vessels there was no evidence of disease present on the most careful examination of all his organs. I have had this patient under constant observation during the last thirteen months and saw him last on Sept. 27th. His general health has remained good during that period. No new mental symptoms have arisen. He informs me, however, that his memory is not quite as good as it used to be, and that this is particularly noticeable in the case of proper names. The right homonymous hemianopsia remains practically the same. With regard to his power of reading there has been a slow but steady improvement during the last six months. During the first six months his condition in this respect was stationary, but during this period I had advised mental rest, and he had made no attempts at reading unless when I examined him now and again. About six months ago, however, I advised him to begin to learn to read. He began by learning the alphabet and spelling through a child's primer. He practised daily, and at the present time he can read, but only slowly and laboriously, spelling out the words letter by letter like a child. In the alphabet at the beginning of his primer he has underlined the letters which gave him difficulty, putting a double line below those which gave him most difficulty. On asking him to read he does so slowly, spelling out each word letter by letter. He makes many mistakes, particularly with the letters which he has underlined in the alphabet. His behaviour is exactly that of a child learning to read. Meeting with the letter F, for example, he hesitates, begins to run over the alphabet from A to F, and then he recognises the letter as F. Meeting with Y, he hesitates for some time, although he says almost at once this is the last letter but one of the alphabet. However, giving him plenty of time and with occasional mistakes, he is now able slowly and laboriously to spell out printed matter. One point very observable in his reading is that he has no difficulty with some short, familiar words. *The*, for example, he always recognises at once without requiring to spell it out letter by letter. This point was also noticeable in a case recorded by Badal which I shall mention later. Badal's explanation seems a very reasonable one—viz., that such familiar words form, as a whole, a picture or graphic unity which is instantly recognised without it being necessary to analyse it into its constituent letters. With regard to written symbols, my patient has not made such marked progress. I tested him on Sept. 2nd last with very clear and distinct handwriting. He could only read a word here and there, and had great difficulty in recognising the letters. The explanation, I think, is very simple. During the last six months he has been reading printed characters every day, while he has not practised constantly the reading of written characters, but only tried it occasionally. This is a point of great interest—the comparative fluency with which he now reads printed as compared with his difficulty with written characters, and the fact that he has been practising constantly the reading of printed but not of written characters. His power of reading figures fluently remains as before. With regard to his power of writing to dictation, he writes as fluently and rapidly as he ever did. He does not spell quite so correctly as he did previously, and his handwriting, though quite legible, is not so good as it was previously to the onset of his word-blindness. The patient himself seeks to explain this by lack of practice in reading and writing during the last thirteen months, and no doubt this is an important factor; but another factor is to be found in the word-blindness, the patient being unable to read what he himself has written, and, therefore, gaining no help from vision in the spelling of the words and the formation of the letters. He is much in the same position as a man writing with his eyes shut.

It was Kussmaul[2] who first clearly pointed out that blindness for words is capable of being met with clinically as an isolated condition, and that it represents the pathological condition of a special faculty. He invented the term "word-blindness" for the condition in which the patient, though not blind, is unable to read visible words. Since Kussmaul's treatise our knowledge of the condition has been greatly increased by the numerous cases which have been reported. It is now evident that the terms "word-blindness," "cécité verbale," and "Wortblindheit" are not sufficiently precise without further definition. There are different forms of word-blindness which must be carefully distinguished from one another. The case just reported is really one of letter-blindness—i.e., the inability to recognise individual letters. In my case the inability embraced all the different forms of letters known to the patient—Gothic and Latin, written and printed. This is not always so. A few cases have been recorded where the visual memory lost for one alphabet was preserved for another. Michel[3] quotes a case where the patient could read the Gothic but not the Latin characters. Charcot[4] had a case where a patient knowing French, German, Spanish, Latin, and Greek lost the memory of a few of the Greek and German characters only. Mierzejewski[3] has recently described a new form of word-blindness which he has proposed to call "cæcitas syllabaris et verbalis, sed non litteralis." The patient could recognise the individual letters and name them, but he could not unite them into syllables and words. Badal[5] has reported a somewhat similar case which merits more detailed description. The patient could see and name each individual letter, but could not combine these even into the simplest syllables or words. A few words she was able to recognise and pronounce, but these were such as were familiar to her from frequent

Digitized by Google

repetition—for example, her own name. Badal's explanation is that such familiar words form a graphic unity, a form picture, which can be recognised at once without resolving it into the individual letters. Badal traced her inability to read to a loss of the sense of space. Although in a given word she saw and could name the individual letters, she did not appreciate their relationship to one another. She could repeat the letters in each word, but not in their proper sequence. She could thus name any individual isolated letter, but when several letters were combined into a word she could not read it, because she could not perceive the relative order in which the letters were placed.

It is thus evident that the terms "word-blindness" and "alexia" are not sufficiently precise. The inability to read may be due to the inability to recognise the individual letters, cæcitas litteralis, or to an inability to combine these into syllables and words, cæcitas syllabaris et verbalis. My case affords a remarkably pure example of cæcitas litteralis, or inability to recognise the individual letters.

One feature of this case to which I wish to direct particular attention is the fact that this patient could read figures as fluently as ever; indeed, it was this feature which first made me suspect that it was a case of word-blindness. On trying him with the test types I was at once struck with the fact that although he could not read a single letter, he read without hesitation the number standing at the top of each paragraph of the test types. I then tested him further with large combinations of figures, and all these were read with the greatest fluency and without any hesitation whatever. This is a point in these cases which has not met with the attention it merits. In the vast majority of the recorded cases of word-blindness no mention whatever is made as to the ability to recognise figures. In the thesis of Mdlle. Nadine Skwortzoff[6] amongst fourteen cases of word-blindness collected by her only one occurs where it is stated that the power of recognising figures was preserved. On quoting this case she remarks that generally we find no difference in word-blindness as to the reading of figures and letters. Cases, however, do occur where the ability to recognise figures remains intact, and that more frequently than was previously supposed. I have met with five recorded cases in addition to my own. In the case of Mierzejewski, already quoted, the patient could recognise and read figures even when these were combined in the most complicated manner. In a case very similar to my own, reported by Brandenburg,[7] the patient suffering from word-blindness and right lateral hemianopsia could recognise and read figures. Brandenburg in his paper quotes a case reported by Joly where the patient suffering from agraphia and word-blindness could recognise figures and also write them. In a case reported by Dejérine[8] the patient was totally word- and letter-blind with right homonymous hemianopsia, but he retained the power of reading figures and could do mental calculations as well as formerly. Alfred Binet[9] has presented us with a very interesting aspect of this same question from another point of view. In his interesting psychological study of MM. Inaudi and Diamandi, who have recently startled the scientific world by their great feats in mental arithmetic, Binet points out that whilst their memory for figures had acquired an abnormal extension, which excited astonishment and admiration, the other forms of memory—e.g., that for words—presented nothing special, and, in fact, in some respects they were below normal. In the case of Diamandi, his extraordinary memory for figures was a purely visual memory. When he learned a series of figures by looking at them for a moment he could repeat them in any order. He explained the mental process by saying that he actually had a precise mental picture of the figures with all their peculiarities of printing and even of colour. His visual memory for figures was so exact as to resemble a mental photograph, which he could read off at leisure, as he would from the page of a book. Yet his visual memory for words was by no means above normal. Experience thus clearly proves the complete independence of the visual memories of letters and figures, for, as we have seen, the one form of visual memory may be lost whilst the other remains intact, and the one form may be developed in excess whilst the other is even below the average.

Another very interesting form of loss of visual memory is that of loss of the visual memory for musical notes—note-blindness. This is a subject which until quite recently had scarcely met with any attention. Professor Edgren of Stockholm has very recently published a striking paper,[10] in which he gives fifty-two cases collected from various sources in which the power of musical expression was partially lost, and which he has designated by the term "amusia." Professor Edgren regards the following conclusions as admissible from the study of the fifty-two cases: (1) that a pathological process can cause partial or total loss of the power of musical expression—amusia; (2) that the various forms of amusia possess a certain degree of clinical independence in their relation to each other and to aphasia; (3) that the clinical forms of amusia appear to be analogous to the clinical forms of aphasia and are often, but not necessarily, accompanied by the analogous form of aphasia; (4) that amusia can exist without aphasia and aphasia without amusia; and (5) it is probable that certain forms of amusia possess an anatomical independence, the region affected being near to but not identical with, that affected in the analogous form of aphasia. Of the different forms of amusia described in this paper one of the most interesting is note-blindness—i.e., loss of the visual memory for musical notes. The patient can see the notes as usual, but has no longer the faintest idea of their significance. This is very frequently associated with another form of amusia, tone-deafness, where the notes are heard, but simply as sounds, without the patient being able to assign them to their position in the musical scale. From the proximity of the visual and auditory centres it is easily understood how these forms are frequently associated together, just as the analogous conditions word-blindness and word-deafness. But note-blindness also occurs as an isolated symptom, there being no other impairment of the patient's powers of interpretation or expression of musical sounds, and the patient being able to read all other printed and written symbols. The patient can read the words of a song, but can no longer read the accompanying music. Word-blindness is very frequently accompanied by note-blindness, but not always, the patient sometimes retaining the power of reading musical notes. It is evident, then, that the visual memory for musical notes is quite distinct from the visual memory for words and letters, since the one form of visual memory may be entirely lost whilst the other is not changed or modified in any way. For illustrative cases I would refer to Professor Edgren's paper.

The following case, which has come under my observation, affords another excellent example of partial loss of visual memory. The loss of visual memory was also associated with right lateral homonymous hemianopsia, just as in my case of word-blindness.

The patient, a married woman aged thirty-eight years, consulted me on Nov. 23rd, 1888, at the out-patient department of the North Riding Infirmary, Middlesbrough, when I was acting there as resident surgeon. She gave me the following history. Twelve months previously she had fallen down in a fit, and for some time afterwards had some loss of power in her right side, and some slight difficulties in speech. During the last three months she had suffered greatly from headaches, which were always worse at night. But it was her visual troubles about which she had come specially to consult me. She was constantly running up against people in the street and against objects such as chairs in her own house. What distressed her even more was that she could no longer find her way about the town. When she went out she could see the houses and streets quite plainly, but she no longer recognised them. She could no longer recognise her own street by sight. She only lived a short distance from the infirmary, but could not come to it alone. She was in the same position as a complete stranger, although she had lived in the town for many years. What was still more distressing to her was that she was quite helpless in her own house and could not do her own household work. She had completely forgotten where things were placed, and most of her time was occupied in looking for the various household articles. The history of running up against people and objects at once suggested an examination of her visual fields. It was found that there was a right lateral homonymous hemianopsia, loss of the right half of each visual field. Unfortunately she was illiterate, so that I could not test her visual acuity by reading the test types. By employing other tests, such as her power of picking up exceedingly minute objects and of recognising dots, &c., it was evident that the visual acuity

in the left half of each field was exceedingly good. The hemianopsia, then, was quite insufficient to account for her visual difficulties. It was evidently a form of mind-blindness, a loss of the visual memory for places. There being a history of syphilis, she was put upon specific treatment. Her general condition greatly improved, her headaches and speech troubles disappeared, but when I last saw her, after three months' treatment, the hemianopsia persisted, and she had still the same difficulties as regards the visual memory for places.

Charcot[11] relates a case in some respects similar to the preceding, but in which the loss of visual memory was much more extensive. Charcot's patient was a highly educated and accomplished man in whom the visual memory had been very highly developed. After a time of great mental worry and anxiety, with loss of appetite and sleep, he was astonished to find that a sudden and profound change had come over him. At first everything was confusion, and the patient feared that he was threatened with some form of mental derangement. In every instance the memory of form and colour had completely disappeared, yet he could perceive them when present without difficulty. Like my patient, the monuments, houses, and streets of the town he dwelt in seemed all strange and new to him. Every time he returned to it, after an absence, it seemed as though he had arrived there for the first time. He could not draw the simplest object from memory, although he used to draw fairly well. When he now tried to draw objects from memory he produced only a shapeless scrawl. He had also lost the visual memory of colours. He found the visual recollections of his wife and children impossible, and even when they were before him their faces seemed strange to him. There was only very partial mind-blindness, he having a difficulty in recognising a few letters of the Greek and German alphabets. His eyes were examined by Parinand and found to be normal.

A very interesting case of object-blindness associated with word-blindness, followed by post-mortem examination, has been recorded by Sérieux.[12]

A female aged sixty-two years had a stroke in 1888, followed by paralysis, and had another attack in June, 1890, with epileptiform convulsions and hallucinations of hearing. When examined on Dec. 16th, 1890, word-blindness and agraphia, and also word-deafness and paraphasia, were found to be present. She was also found to be suffering from marked object-blindness, which was exhibited by the inability of the patient to recognise her relatives and friends when they called upon her. Their faces and figures seemed to her to be quite changed, and, as she expressed it, all the people about her seemed to be wearing masks. This object-blindness, although best marked in relation to faces, was also manifested in relation to the familiar objects about her, although to a less extent. A few months afterwards she died from pneumonia. On examination of the brain a bilateral cortical lesion was found. On the left side there was a softening in the supra-marginal convolution, and also a limited patch of softening in the posterior extremity of the first temporal. On the right side there was a large patch of softening involving the angular and supra-marginal convolution and also the posterior extremities of the first and second temporal convolutions.

I have quoted these additional cases in order to make the conception of the visual memory more complete. But what is meant by the terms "memory" and "visual memory"?

It is customary and correct to employ the term "memory" in a general sense to express the power, which all rational beings possess, of preserving and of reproducing impressions previously received. In psychology up till recent times memory was regarded as a special faculty and as an indivisible unity. But the new psychology, expounded with lucidity by Ribot[13] and by Binet,[14] teaches that the word "memory" is simply a general term reducible to particular cases, that such a unity as memory does not exist, but that individual memories do exist—e.g., memories of vision, of hearing, of taste, of smell, of movements, and so forth. The facts of mental physiology and pathology have clearly shown that we must not regard the memory as a single faculty having a definite location in the brain. The memory is really the sum total and result of a number of distinct mental processes. There exist partial, special, or local memories, each of which has its own special domain—all of which have intimate connexions with one another, yet possess an independence of each other such that one of these special memories can be enfeebled, lost, or developed to an abnormal degree without any of the other forms necessarily presenting any corresponding modifications. These special or local memories are both motor and sensory. Of these the sensory memories form a most important group. Each organ of sense has its cortical centre in the brain, where not only fresh sensory impressions are received, but also previous sensory impressions are stored up and linked with associated sense impressions stored in other centres. Our primary and most simple ideas of objects are formed by the revival in our minds of these sensory memories.

The member of this group which concerns us is the visual memory. There is in the cortical centre of vision situated in the angular and supra-marginal convolutions a storehouse of past visual impressions. These can be called into the sphere of consciousness at will when we form what we call a mental picture, or, according to the French nomenclature, a visual image. To put it concisely, the visual memory means the power of preserving and of recalling to consciousness past visual impressions. It is only through the help of this visual memory, of this storehouse of past visual impressions, that we can interpret the fresh visual impressions that are constantly passing to the brain. Sweep away the visual memories or images from the brain, and you have the condition commonly known by the term "mind-blindness." In this condition the object is seen, but there is no intelligent perception of it. There are no past visual impressions to compare it with, and through the medium of the visual memory to arouse the other sensory and motor memories regarding it. Hence the object, though seen, has no significance whatever for the mentally blind. Mind-blindness, then, is simply loss of visual memory. We must carefully distinguish between simple perception of an object and an intelligent knowledge of it. If retina, optic tract, and percipient centre in the occipital lobe are intact, then we shall be conscious of the image of any object which falls upon the retina, and may assign it to its proper position in the external world. But we may have no intelligent knowledge of it. The visual memory centre must be communicated with, the present visual impressions must be compared with similar past visual impressions, and through the medium of the visual memory we arouse the other sensory memories regarding it, all of which are closely associated. The visual memory, then, plays a most important part in every conscious exercise of the vision. But it is evident from the study of the facts of mental pathology that this visual memory is not a unity. We have seen that the visual memories for words and letters, for numbers, and for musical notes have a functional independence of each other. Each group of visual memories may be entirely lost, whilst the others remain intact and unaffected in the slightest degree. Hence we are led to infer that they must possess an anatomical independence. We can as yet only localise the visual memory of words and letters, but from the frequency with which these three groups of visual images are simultaneously lost we can infer that the regions affected, though not identical, are probably very close together. Further, these three groups have this in common, that they are highly specialised visual memories, requiring for their retention in the brain a considerable amount of mental concentration and education.

There are other groups of visual memories which are not so highly specialised, and for the acquirement of which comparatively little mental concentration or special training is necessary. The visual memory of form and colour, of objects and places, furnishes us with a mental picture gallery which enables us to find our way with unerring accuracy through the intricate streets of a great city, which enables us to recognise a friend after the lapse of years, and which puts us in an intelligent relationship with the objects around us in our daily life. That this form of visual memory is distinct from the highly specialised visual memories of words, numbers, and musical notes is clearly shown by the clinical evidence. Word-blindness and note-blindness are but seldom accompanied by any impairment of this larger group of visual memories. We have seen, as in Charcot's case, that a great impairment of this group of memories may exist and yet the patient be able to read and write. Further, this form of mental blindness for form and colour, for objects and places, is of great rarity, whereas the loss of the highly specialised visual memories is comparatively common. I would thus divide the forms of visual memory into two main groups:

first, a group of highly specialised visual memories for the acquirement of which great mental concentration is necessary, and which are possessed only by those specially trained; and, secondly, a group of visual memories for form and colour, for objects and places, for the acquirement of which no great mental effort is required, and which are possessed by all men who have the sense of vision. We are led to infer from the complete functional independence of these two groups of visual memories an anatomical independence, and a plausible suggestion has been offered as to why the loss of the first group should be comparatively common as compared with the loss of the second.

The organs of sense that are concerned in the reception and interpretation of speech are represented bilaterally in the cerebral cortex. Since each eye and each ear are connected with both hemispheres destruction of the cortical centre in one hemisphere will not make the patient deaf in one ear or blind in one eye. Destruction of one occipital lobe causes, as we shall see, a homonymous hemianopsia only. But with regard to language the education of these sensory centres is unilateral. In the auditory and visual centres of one hemisphere only are the sensory impressions of language, visual and auditory, retained and stored up. The hemisphere selected is always that in which are situated the motor centres for speech and writing. It is thus the left hemisphere in right-handed people and the right in left-handed people. A lesion on one side of the brain, in the vast majority of cases on the left side, may completely obliterate the visual word memories and make the individual word-blind. The visual memories of numbers and musical notes are also probably unilateral and in the immediate neighbourhood of the word centre, for, as already pointed out, all three groups of visual memories are frequently lost together. It has been suggested that the second group of visual memories—those of objects, of places, of form, and of colour, which do not require such an effort of attention and concentration—are efficiently imprinted and stored up in the higher visual centres of both hemispheres. Hence it would require a bilateral lesion to produce object-blindness, and hence, as can be readily understood, its much greater rarity. The case of Sérieux, already quoted, supports this view, where the patient suffered from word- and object-blindness, and where, after death, was found a bilateral lesion in the brain involving the left supra-marginal convolution and the right angular and supra-marginal convolutions. This, however, is a subject which is by no means settled and which awaits further investigation.

A notable feature in both my cases of loss of visual memory was their association with right lateral homonymous hemianopsia. This condition also existed in Charcot's case of word-blindness, already referred to. According to Charcot, a similar hemianopsia associated with word-blindness was to be found only in one other observation, that of Westphal.[15] Since then, however, many cases have been recorded, and I am able to quote nine additional cases. Two cases have been recorded by Samelsohn,[16] two by Wyllie of Edinburgh,[17] and two by Henschen of Upsala.[18] One case has been recorded by Brandenburg,[19] one by Dejérine,[20] and one by Bruns and Stoelting.[21] In all these cases word-blindness was associated with right homonymous hemianopsia. As we have cases of word-blindness without right hemianopsia, and as we have right hemianopsia without word-blindness, it is evident that the cerebral centres for the right halves of both visual fields and for the visual memory of words must be distinct from one another. Yet these symptoms are associated with such frequency as to lead to the inference that the cerebral centres or the paths to them must lie in close proximity to one another. We shall see that pathological evidence confirms the inference drawn from clinical experience.

The question of the exact localisation of the visual centres in the brain has given rise to considerable controversy in the past. For a considerable time Ferrier and Munk carried on a discussion on this subject. Ferrier originally held that the cerebral centre of vision was situated in the angular convolution, and Munk that it was in the convolutions in the posterior part of the occipital lobe. Recent clinical and pathological observations[22] are reconciling these apparently antagonistic opinions by showing that both Ferrier's centre and Munk's centre have important parts to play in the function of vision. It has already been pointed out in this paper that in the act of vision we must distinguish between the mere perception of an object, as occupying a certain position in our visual field, and an intelligent knowledge of it, as to its exact nature and qualities. Although the boundaries of the visual centres cannot as yet be laid down with precision, yet the mass of pathological evidence tends to show that the occipital lobe, especially in the neighbourhood of the cuneus and the calcarine fissure, is the centre for primary visual impressions, the perceptive centre, and that in the angular convolution and its neighbourhood there is a centre of a higher nature, one of whose functions seems to be the storage of the visual memories of things and words, the visual memory centre. It is evident from what has already been said that the functional activity of both these centres must be called into play in every conscious and intelligent exercise of vision. It is now a matter of general agreement that the primary visual centre in the occipital lobe is connected with the half of the retina in each eye, the left occipital lobe with the two left halves and the right occipital lobe with the two right halves. But since the left half of each retina corresponds to the right half of each visual field a lesion in the left occipital lobe would produce blindness in the right halves of both visual fields, or, in other words, a right hemianopsia. The hemianopsia is termed homonymous because it is on the same side in relation to both eyes. A lesion of the right occipital lobe would produce left homonymous hemianopsia. To put it concisely, destruction of the primary visual centre in the occipital lobe produces homonymous hemianopsia in the opposite half of the field of vision. It is also known that a lesion in any part of the optic tract from the cerebral cortex to the optic chiasm will produce homonymous hemianopsia.

In my case of word-blindness, however, there are two points which lead us to infer that the lesion causing the hemianopsia is in or near the cortex. 1. When a beam of light fell upon the blind half of each retina the pupil contracted actively, just as when it fell upon the seeing half. Wernicke first pointed out that if there be loss of the reflex movement of the pupil, when light is thrown upon the blinded portion of the retina, the break in the conduction must lie below the spot at which the fibres to the oculo-motor nucleus are given off—i.e., it must lie in the optic tract itself. This valuable diagnostic symptom has been called Wernicke's hemiopic pupillary reaction. But when, as in my case, the pupillary light-reflex is intact, the lesion is to be located higher up, in the internal capsule, the optic radiations, or in the cortex of the brain. 2. The association of the hemianopsia with word-blindness, which is known to be always dependent on a cortical or sub-cortical lesion, leads us to infer that the right homonymous hemianopsia is due to a lesion in the cortex of the occipital lobe or of the optic radiations passing to it. The frequent association of right homonymous hemianopsia with word-blindness, already referred to, thus confirms the results of pathological experience, that the centre for the visual memory of words is in the neighbourhood of the left occipital lobe.

Although its boundaries have not yet been finally laid down, still a constantly increasing pathological experience[23] tends to prove that the centre in which are stored the visual memories of letters and words includes the supra-marginal and angular convolutions, both of which belong to the inferior part of the parietal lobe. Pathological experience also shows that the more important part of the centre is situated in the angular convolution, which is bounded posteriorly by the occipital lobe. It has already been pointed out that the visual centre forms no exception to the law that with regard to language the education of the motor and sensory centres is unilateral. The hemisphere selected is always that in which are situated the motor centres for speech and writing, hence in right-handed people, forming the vast majority of cases, the visual memory centre for letters and words is situated on the left side of the brain in the region already described. This centre in the left angular gyrus and neighbourhood is

connected with both occipital lobes, hence destruction of the left occipital lobe causes right homonymous hemianopsia, but not word-blindness, since the right occipital lobe is still connected with the visual word centre in the left angular gyrus. To have complete word-blindness the centre itself must be destroyed or its connexions with both right and left occipital lobes must be cut off. The visual word centre is supplied with blood by the sylvian artery, and it is a significant fact that all the cerebral centres concerned either in the expression or in the interpretation of language are situated within an area supplied by the same vessel. The speech-motor centre, the graphic centre, the auditory word centre, and the visual word centre are all supplied by branches of this sylvian artery, hence it is easily understood how disturbances of all the centres or some combination of them are so frequently associated; further, in consideration of the immediate proximity of the visual and auditory word centres, the auditory being in the posterior part of the first convolution of the temporo-sphenoidal lobe, it is manifest how the symptoms of word-blindness and word-deafness are associated with such great frequency. My case of word-blindness is a pure example of the rarer condition of isolated lesion of a single centre, all the other centres concerned in language being intact. The patient could speak, write, and understand spoken language as well as ever he did.

I have dwelt particularly on the fact that my word-blind patient could write fluently to dictation, although he could not read what he himself had written. The old explanation put forward to account for such cases was that by constant and prolonged practice the motor images of writing had become so deeply imprinted upon the graphic motor centre (in the second frontal) that without any aid from the visual centre the revival of these motor images was quite sufficient to guide the hand to form the letters correctly. It has been shown, however, by the recent observations of Déjérine and Sérieux[24] that when the visual word centre is destroyed the patient can neither read nor write. He is agraphic because he can no longer call up in his mind the visual memories of letters which are necessary to stimulate the graphic motor centre. How, then, are such cases as mine to be explained where there is complete word blindness without agraphia, and where the patient can write fluently, although he may not be able to read a single word of what he has written? It is now maintained that in such cases the visual word centre is intact, and also its connecting path with the graphic motor centre, but that the pathways connecting the primary visual or preceptive centres in both the occipital lobes with the visual word centre in the left angular convolution are cut across. Hence the visual memories of words and letters can still be revived from within, and serve as a guide to the graphic motor centre; but impressions from without from the preceptive centres can no longer reach the visual word centre because of the interrupted pathways. Such an explanation is in perfect harmony with the facts observed in my case. I found that the patient, even when unable to read a single letter, still possessed the power of calling up at will the visual images of all the letters. He informed me that when I mentioned any letter he could mentally see it just as well as ever he could. Hence the patient could write because he had still the power of reviving the visual images of letters, and to accomplish this the centre itself must have been intact. How, then, could he no longer recognise these same letters which he had written? Because the visual word centre was cut off from the primary visual centres in the occipital lobes, and hence could not be reached by any visual stimulus from the external world. I would refer particularly to a case recorded by Déjérine[25] in which the post-mortem examination supported in a very striking manner the view expressed above. This case is particularly interesting, as it presents almost the identical group of symptoms which were met with in my case of word-blindness.

Déjérine's patient was a man sixty-eight years of age who, after a number of attacks of tingling in the right arm and right leg, suddenly perceived that he was unable to read a single word. Although word-blind he could write as fluently as ever. He could copy correctly pages of manuscript, although he could not read a word he had written. He had also lost the power of reading musical notes (note-blindness), but he could still sing well. He could read figures and do mental calculations just as well as ever. On examination with the perimeter he was found to be suffering from right homonymous hemianopsia. Ten days before his death he was suddenly seized with paraphasia and total agraphia. There was no muscular paralysis, and his intelligence remained clear until his death, which occurred suddenly. On examination of the brain there was found (1) an old lesion, a softening which had destroyed the cuneus and some of the neighbouring convolutions of the left occipital lobe and had extended deeply into the white matter so as also to cut across the fibres passing from the right occipital lobe to the left angular convolution—this old lesion thus accounted satisfactorily for the hemianopsia and for the word-blindness without agraphia which had persisted for four years; and (2) a recent lesion—viz., a softening of the left angular and supra-marginal convolutions, which explained the recent appearance of the total agraphia. The paraphasia was probably caused by disturbance of the auditory word centre, which is in the immediate neighbourhood. For other illustrative cases I would refer to the papers published by Déjérine and Sérieux, to which I have already called attention.

It is thus evident that in my case the word-blindness and the right lateral homonymous hemianopsia may be accounted for by a single lesion. We have seen that interruption of the optic radiations as they pass to the occipital cortex produces a lateral hemianopsia, just as when the occipital cortex is destroyed. A subcortical lesion in the white matter of the left occipital lobe, so situated as to cut across the fibres passing from both occipital lobes to the left angular gyrus, would render the patient word-blind but not agraphic. As such a lesion must involve the optic radiations passing to the left occipital cortex, the patient would have at the same time right homonymous hemianopsia. As to the probable nature of the lesion, the absence of all signs of disease, with the exception of atheromatous vessels, and the non-progressive course after the lapse of thirteen months would suggest as the most probable condition a spot of softening due to hæmorrhage or thrombosis. One of the most interesting features in this case was the slow but gradual improvement of the patient, which I have already described in detail. In most of the recorded cases of word-blindness, unfortunately, there is no account of their after history. In the after histories which are given the patients seem only very rarely to have recovered the power of reading. We know that in aphasia, particularly in youthful patients, the power of speech is sometimes recovered even after complete destruction of the speech centre in the left side of the brain. That the recovery in these cases is due to education of the corresponding centre in the opposite side is, I think, demonstrated by Barlow's[26] case of cerebral lesion, first in the left third frontal convolution and then in the corresponding convolution of the right side.

The patient, a boy suffering from heart disease, had first an attack of aphasia due to embolism in the artery supplying the left third frontal convolution. He speedily regained the power of speech by training the corresponding right third frontal convolution. A second embolism plugged the artery supplying this convolution also. The patient had a second attack of aphasia, which, however, was permanent. Have we in the patient who forms the subject of this paper a case of education of the corresponding centre in the opposite side of the brain, or is it that the interrupted paths have been repaired, or that new communicating paths have been found leading to the word centre in the left angular gyrus, which we regarded as still intact? I offer no definite opinion, and our knowledge is as yet too imperfect to dogmatise. I content myself with enumerating three striking facts: (1) the permanence of the hemianopsia, which is practically the same as at the outset of the attack; (2) the slow and gradual acquisition of the knowledge of printed letters, but only after persistent education and practice; and (3) the comparatively slight improvement in the knowledge of written letters, the study of which has not been carried out with the same steady perseverance.

In conclusion I would ask, Why have we such scanty records of cases of mind-blindness, or, as I prefer to designate them, cases of loss of visual memory? I venture to affirm that through lack of knowledge the true nature of such cases, when they do occur, is very frequently not

recognised. I would urge the most careful examination of all patients suffering from visual derangements where there are no ocular changes to account for them. It is only by the painstaking analysis of symptoms and the careful recording of such cases, followed, where possible, by pathological examination, that we can hope to gain any further knowledge of the complex cerebral processes involved in vision, of which at present we can only form a very faint and imperfect conception.

ON THE TREATMENT OF IMPACTED FRACTURE OF THE NECK OF THE FEMUR BY BREAKING DOWN THE IMPACTION UNDER ANÆSTHESIA.

BY F. A. SOUTHAM, F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY; LECTURER ON OPERATIVE SURGERY, OWENS COLLEGE.

IN THE LANCET of Nov. 17th, 1894. I called attention to the unsatisfactory result which attends the usual method of treating impacted extra-capsular fracture of the neck of the femur. This consists in simply keeping the limb at rest, no attempt being made to correct the characteristic deformity—the shortening and eversion (rarely inversion) of the limb, always present in a greater or less degree—for fear that if the impaction is broken down the fracture will not unite. The result is that the patient remains with the limb shortened and everted, and consequently more or less crippled for the remainder of life. A case of this injury occurring in a male aged twenty-seven years was described, where the fragments were loosened by forcibly breaking down the impaction under anæsthesia, and, the shortening and eversion having been corrected, perfect union took place without any deformity resulting. Three cases have since been treated according to the same method in the Manchester Royal Infirmary (two under my own care and one under my colleague, Mr. Whitehead) with satisfactory results, especially as regards the correction of the eversion, and as the patients were aged respectively fifty, sixty-five, and seventy-five years, a brief record of each may, perhaps, be interesting, for they illustrate the fact that advanced age is in itself apparently no bar to this procedure, the fracture in each instance readily uniting with an abundant formation of callus after the impaction had been broken down.

CASE 1.—A woman aged seventy-five years was admitted to the infirmary under my care on Dec. 20th, 1894. She was examined on admission by Mr. J. H. Ray, house surgeon, who found that the right lower extremity was shortened to the extent of an inch and a quarter and well everted; the trochanter was thickened; crepitus was absent, and the limb could not be inverted. The patient having been anæsthetised the fragments were loosened by Mr. Ray, who felt the bone give way with a "crunching" sound; the limb could then be inverted and moved freely about a point just internal to the great trochanter. A straight splint reaching from the hip to the ankle was bandaged to the outside of the limb, and extension was applied in the usual way by means of a weight (8 lb). As some slight chest symptoms developed the patient was allowed to sit up in bed after a few days, and at the end of three weeks she was placed on a couch during the daytime with the limb between sand-bags, the extension being only applied at night. On Feb. 5th she went home. The limb was shortened to the extent of about half an inch and was very slightly everted. As she lay in bed she could flex the thigh to an angle of 45°, and the movements at the hip-joint were quite free. With support she was beginning to bear her weight on the limb and walk about the ward.

CASE 2.—A woman aged fifty years was admitted to the infirmary under my care on July 2nd, 1895. On examining her the following morning I found that she presented all the usual signs of an impacted extra-capsular fracture of the left femur—viz., shortening to the extent of about half an inch with slight flattening over and thickening of the trochanter in an antero-posterior direction, also marked eversion, the toes pointing directly outwards. There was an absence of crepitus. Attempts to correct the deformity by rotating the limb inwards caused great pain and produced no effect. Under anæsthesia the impaction, which was very firm, was broken down with a grating sound, though it was not until the thigh had been flexed to an angle of 45° and the knee bent to a right angle that enough force could be brought to bear upon the limb to loosen the fragments sufficiently to completely correct the eversion. On making traction upon the leg after the fragments had been loosened it could be restored to the same length as the other. A Liston's long splint was bandaged to the outside of the limb and extension (9 lb.) applied. On July 29th the splint and extension were removed and the limb was fixed in a plaster-of-Paris bandage. When this was taken off at the end of a month the fracture was firmly united without any perceptible shortening or eversion of the limb. The movements of the hip-joint were quite free, and in the course of a few days she was able to walk without assistance.

CASE 3.—A man aged sixty-five years was admitted to the Infirmary on Sept. 8th, 1894, under the care of Mr. Whitehead (who has kindly allowed me to include the case with the preceding). On examination the left lower extremity was found to be shortened to the extent of two inches; there was well-marked eversion, which could not be overcome by ordinary passive movement; crepitus was absent; and the trochanter was thickened. The patient having been anæsthetised, the impaction was broken down by Mr. J. W. Smith, resident surgical officer, assisted by Mr. Ray, and, the deformity having been corrected, the limb was fixed on a Liston's long splint, with 5 lb. extending weight. The patient was kept in the recumbent position, which was well borne, until Oct. 1st, when the splint and extension were removed; it was then found that firm union had taken place, the limb being very slightly everted and shortened to the extent of three-quarters of an inch. It was put up in a plaster-of-Paris bandage, and the patient left the hospital on Oct. 4th. He has since resumed his former occupation, that of a waiter, and though he walks with a limp and the limb slightly everted, wearing a thick sole to the boot, he is able to rotate the foot inwards and has good movement in the hip-joint.

I am indebted to Mr. Ray for notes of Cases 1 and 3.

Manchester.

MORTALITY FROM EMPYEMA IN CHILDHOOD.

BY LEWIS W. MARSHALL, M.D. ABERD.,
SURGEON TO THE CHILDREN'S HOSPITAL, NOTTINGHAM.

THE publication of the interesting statistics by Mr. Wightman in THE LANCET of Nov. 30th, 1895, has induced me to collect the cases of empyema which have been under my own care since May, 1879. The statistics alone, when read in connexion with the paper referred to, must be of value, because the percentage of recoveries at all ages is more favourable than in the lists supplied by Mr. Wightman. All my cases have been treated by free incision with the exception of two, where, owing to the grave condition of the child and the extent of the effusion, it was deemed to be wiser to relieve the chest by a limited aspiration some hours before proceeding to free incision. This I believe to be a very useful precaution, it being impressed very much on my mind in the case of an adult female who had an enormous left-sided collection after parturition. The total number of my cases was forty-five, the deaths being seven. In the foregoing list I find that only seven cases were under three years of age, and of these two died, one child being a year old and the second a year and nine months. The method of treatment in every case may be briefly summarised as follows: (1) free incision; (2) a single tube in infants, but a double-barrelled tube in all above the third year; (3) the complete emptying of the chest of fluid for the first week twice daily by turning the child on to his side as one would empty a barrel, this being assisted by an effort of coughing when the child is old enough to understand what is needed; (4) the early removal of the tube—i.e., at the end of the first week; and (5) allowing the patient to sit up and move about as soon after the first week as possible, thus helping the expansion of the lung. I may here add that I have never found it necessary to remove a portion of a rib in an acute case.

In connexion with the deaths the following facts are distinctly noteworthy: (1) that with one exception all the

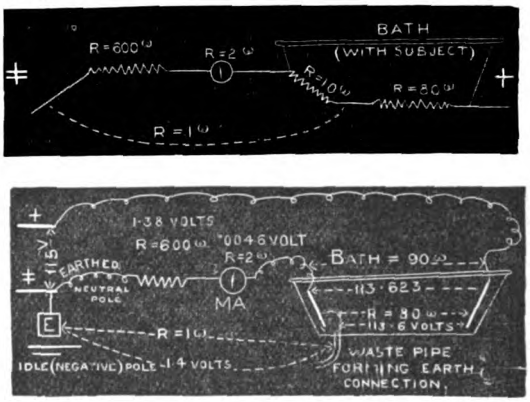
Digitized by Google

fatal cases were those of effusion on the *left* side—this is very interesting, and confirms the belief held by some that left-sided pleuro-pneumonia is always more dangerous to life than when it occurs on the right; (2) in all there was a long history of illness before admission, varying from six weeks to three months; (3) in one gangrene of the lung was believed to exist, but this could not be proved post mortem: (4) of the two deaths occurring in children under two years of age, one was the direct sequence of chicken-pox, and in both the children were rachitic to a degree; and (5) one case suffered from thrombosis of the left iliac vein six days after operation, and he died on the eighth day.

The deductions I would draw from these facts are as follows: (1) that free incision when done early is very successful; (2) that the removal of a portion of a rib is never necessary in acute cases; and (3) that a fatal issue at any age is rather the result of the neglect to recognise the true nature of the case than from the operation itself.

Nottingham.

CURRENT FROM THE MAIN.



BY W. S. HEDLEY, M.D. EDIN.,

MEDICAL OFFICER IN CHARGE OF THE ELECTRO-THERAPEUTIC DEPARTMENT OF THE LONDON HOSPITAL.

SINCE the publication under the above heading of two articles on the utilisation of public supply currents for electro-therapeutic purposes[1] great progress has been made in the supply of electricity from central stations. The same interval has brought forth a variety of apparatus as well as a somewhat extensive literature bearing upon the points in question; but it cannot be said that by any writer has there yet been shown a complete grasp of the subject, nor by any instrument have the many serious difficulties of the case ever been adequately met. In view, however, of the great and increasing employment of these currents, and with an experience of their usefulness in medicine, the time seems to have arrived for a complete survey of the whole problem; and the following remarks offer themselves as an attempt at its solution.

Considering the improvement that has taken place in public supply currents, I am of opinion that for medical employment their chief danger now lies, not in the possible influx of strong currents or in the chances of a failure of supply, but in leakage currents and in the breakdown of transformers, and of these risks the greater is leakage.

1. *Leakage currents.*—This source of danger has hitherto been either under-estimated or completely ignored, but it is nevertheless a very serious one, and in the absence of suitable precautions may lead to accidents of a grave kind. Those stations which supply by direct distribution, or distribution from transforming centres, are undoubtedly, and for obvious reasons, more subject to earth leakage than are those in which transformers are used at or near the house. Again, stations supplying electricity on the three or five wire systems, even if they do not actually connect to an earth plate or water pipe, are likely to have the middle wire (the "neutral") at practically earth potential. It is true that any connexion to earth of a main supplying current direct to houses is forbidden by the Board of Trade, but when, for purposes of its own, it suits a company to earth its middle wire this regulation does not seem to bar the practice. Now, if under these circumstances the patient be placed in contact with one of the outer mains (positive or negative) what may be expected to happen? If the connexion to earth be good, even a damp floor, such a patient would be subjected to the full pressure of supply, usually 100 volts or more. It is obvious that if the contact be of low resistance (for instance, if the patient be in an uninsulated bath) the resultant current through the patient's body might be one of considerable and even dangerous magnitude, perhaps approaching 400 milliampères. It would be useless to interpose resistance between the patient and the uninsulated (neutral) pole, as this portion of the circuit would be shunted by the leakage current, and if the milli-ampère meter was also placed in this portion of the circuit it would fail to register any of this leakage. The following diagrams[2] will serve to illustrate the electrical conditions that exist—for example, in a bath—when an earth connexion is made.

There is one "series" R = 80 and there are two parallel branches (R = 600 + 2 + 10 and R = 1). Then the total resistance $= \frac{612 \times 1}{612 + 1} + 80 = 80{\cdot}998$, and the total current $\left(\frac{115}{80{\cdot}998}\right) = 1420$ m.a. Of this total the body will take an average of 25 per cent.[3]—that is, it will receive 355 m.a. The current in the respective parallel branches will be as 612 : 1—in other words, the milliampère meter will register 2·3 m.a. Had the patient been placed in contact with the uninsulated (neutral) wire and the resistance been interposed between him and the insulated pole (positive or negative) he would not, even if placed in an uninsulated bath, have been in the circuit of any earth current. This would hold good only so long as the condition of the mains was good. Should a fault break out on one of the outer wires (positive or negative) the state of affairs would be in no way different from the case just considered. What, then, is the remedy for this risk? Clearly insulation. It should be taken as an axiom that the current from public supply mains should *never* be applied either as a shunt or direct to the patient without interposing between him and the earth an insulating substance of such a nature as would undoubtedly stand the full main pressure across it without passing a current of 1 m.a. In the case of three wire systems the "full main pressure" would be double that of supply, and in five wire systems four times that of supply. This necessity for insulation would apply equally to all systems, whether continuous or alternating, direct or transformed. In the usual electrical applications security would be attained by standing on a very dry floor or, more certainly, on a varnished kamptulicon mat. But in the case of the water bath, connecting as it does with a good earthing device in the shape of waste pipes and water pipes, the case is altogether different, and certain additional precautions then become necessary. With these duly carried out effective insulation can certainly be secured. In the first place it is obvious that the bath should not be made of metal. Hard wood or porcelain are suitable materials, the latter by preference. The bath should stand upon glass mushroom insulators filled with a heavy resinous oil (similar to those used for insulating storage batteries) or it might be placed upon hard vulcanised rubber blocks. The inlet stopcocks for both hot and cold water should be placed some distance from the bath, and in such a position that it would be impossible for the patient, when in the bath, to accidentally make contact with them. An insulating piece of porcelain or vulcanised rubber should be inserted in both inlet pipes between the stop-cocks and the bath. If the waste pipe be attached to the bath an insulating piece should be inserted as close to the bath as possible. But danger may be even more easily and effectually averted by fixing directly below the waste outlet of the bath

[1] Current from the Main. By W. S. Hedley, M.D., THE LANCET, Dec. 19th, 1891, and April 9th, 1892.

[2] These diagrams are only intended to show by an example the possible danger to a patient from leakage currents. 115 volts is the full pressure of the mains. The total current under the above conditions is 1420 m.a., and the resistance in the respective branches is 612 ohms and 1 ohm, and, as current is inversely proportional to resistance, the current in the circuit of high resistance (the galvanometer circuit) will be 2·3 m.a., and in the earth circuit 1417·7 m.a. But both circuits are common to the bath.

[3] My most recent experiments, shortly to be published, prove this—a conclusion in startling contrast with former surmises.

Digitized by Google

a shallow tank or sink to receive waste water from the bath, the waste pipe being attached to this sink. Neither the tank nor the waste pipe should make contact with the bath.

I have just read, and not without misgiving, the report of a discussion at the recent conference of the Board of Trade upon the question of raising the limit of low-pressure supply. It cannot be said that on this occasion the calculations of the commercial electrical engineer were hampered by any undue regard for the safety of human life. It was claimed by several of those present that they had received harmless shocks from what are now considered to be high-pressure circuits. One gentleman asserted that he had felt no ill effects from a 600 volt shock. In view of the fact that so much depends upon contact and the manner of taking a shock, and that little or no information was given on this point, it is difficult to form an opinion from such a statement. Did the gentleman in question touch one pole only of a 600 volt circuit? If so, what was the earth insulation of the other pole? Was his body in contact with the earth? Or, presuming that he simultaneously placed one hand on each pole of the 600 volt circuit, what was the surface area of skin contact, and what the condition of the skin? In the absence of information on these points the statement referred to cannot be considered to have any real value. Had the surface area and condition of the skin been favourable for a low resistance contact, it is more than possible that the gentleman in question might ere this have been "put to earth" in a sense other than an electrical one.

2. *Breakdown of transformers.*—The second source of danger (one which, of course, can occur only with transformed systems) is that due to the breakdown of the insulation between the primary and secondary windings of a transformer. This risk does not belong exclusively to alternating current systems. Continuous current transformers are now used in several public installations, notably at Oxford (1000 volts primary) and at Chelsea (500 volts primary). In the event of a breakdown of the insulation the secondary mains would have their potential above earth very considerably raised, and should it happen that there are weak places in the network of secondary (distributing) mains (of which the patient's body, unless well insulated from earth, would form one) an excessive current would pass, with probably fatal results to the patient. The Board of Trade regulations provide that every secondary circuit of a high-pressure main shall be fitted with an approved form of apparatus for automatically connecting the secondary mains to earth in the event of their potential above earth rising to a dangerous degree; but in this case there is the not improbable contingency that when the occasion for its action arises such an apparatus will be out of order, and, even if it be working well, it cannot act until the potential above earth of the mains has risen to this dangerous degree. And after that there is still an interval, short but quite appreciable, required for the action of the device in question. It must be borne in mind that during this time the excessive potential is acting upon the patient unless he be very well insulated, and, further, that it does not take long, with good contacts, to kill a man with 1000 or 2000 volts. What, then, are the precautionary measures here? Never to rely solely upon the insulation of the patient from earth when the supply is a transformed one, but always to place a substantially made transformer in the circuit. With alternating currents a "Woakes"[4] or "Miller and Woods"[5] transformer may be used; but it should be tested with at least the pressure of the primary mains between its primary and secondary windings before being installed for work. With continuous currents from a transformed system it will be well to interpose a motor, and make this drive by belt a small dynamo which should *not* be fixed on the same metal bed-plate. The dangers due to leakage and the breakdown of the transformer represent practically the whole of the difficulties that have to be contended with so far as the company's mains are concerned. The risks of failure of supply and serious rise of supply pressure need not, in the case of English companies at least, now be seriously considered. The companies for their own sakes take every possible precaution to guard against these accidents, and usually with complete success. Under any circumstances it is desirable to fix upon each pole of the electro-therapeutic circuit a reliable magnetic cut-out. The best apparatus of this kind is that known as the "Cunyngbame," of which the following is a description. Two planished ends of a copper solenoid dip into two mercury cups forming the terminals of the instrument, and on the current reaching a predetermined amount the solenoid is "sucked over" (drawn back upon) a curved, soft, iron core-piece, the position of which is fixed but adjustable. The solenoid is fastened to one end of a radial arm which is pivoted at its lower end in such a way that a slight movement of the solenoid brings it vertically over the turning centre and into a position of unstable equilibrium; any further increase of current will cause the solenoid to drop by force of gravity and at the same time withdraw the contact points from the mercury cup, thus breaking the circuit. If desired, the mercury cup could be short-circuited by a resistance of such an amount as would reduce the current in the circuit to half or quarter of the breaking current. For example, let it be supposed that the magnetic cut-out has been set to break circuit at 200 m.a., and that the electromotive force of supply is 100 volts, then the resistance to the circuit must be $\frac{100}{\cdot200} = 500$ ohms. Now, if the magnetic cut-out be short-circuited with a resistance of 500 ohms, the current, instead of ceasing altogether, would be diminished to $\frac{100}{500 + 500} = 100$ m.a.; or, if 1500 ohms be used as a short-circuiting resistance, the current would have been diminished to $\frac{100}{500 + 1500} = 50$ m.a.

Where two magnetic cut-outs (one on each pole) are used it would be well to short-circuit both instruments with resistances, and to set one to act a little in advance of the other. Fusible cut-outs and lamps in the circuit have been recommended as safeguards, but it has been more than once pointed out by me in THE LANCET that at best such devices are unreliable for the purpose in question and may lead to the serious discomfiture of those who put their trust in them. It is well known that fuses cannot be guaranteed to act within 5 per cent. of their nominal current; it is necessary also to remember that even then they take quite an appreciable time to heat and melt. Again, the difficulty of obtaining small fuses of reliable gauge is greater than with fuses of larger capacity. With lamps the result is even more uncertain. The resistance of carbon diminishes as the filament grows hot until the state of incandescence is reached, after which resistance remains practically constant. Again, the temperature to which it is raised under normal lighting conditions depends entirely upon the efficiency (watts per candle) at which the lamp is intended to burn: therefore it is evident that as a fuse a lamp's breaking point must vary considerably. With high-efficiency lamps—i.e., with lamps which absorb small voltage for candle-power—the ratio between the nominal current and the fusing current will be less than with low-efficiency lamps. Used as a "backing" resistance—i.e., as a choking or current-reducing resistance of steady value—a lamp to ensure anything like reliability should have a considerable current passed through it—certainly full incandescence should be attained. As safeguards, therefore, for electro-therapeutic purposes fusible cut-outs and lamps are entirely out of the question.

Having cleared the ground of the only serious difficulties that lie in the way of utilising lighting currents, I hope to go on to consider their physical characters, their therapeutic qualities, and the control apparatus by which such currents may be best adapted to the varied requirements of practice.

[4] This instrument has on one bobbin three separate secondary coils; one supplies cautery, the second light, and the third gives current for application to the patient.

[5] This device is provided with a number of terminals on the secondary winding, such that any voltage from 2 upwards and any current up to 20 amperes can be obtained.

A CONTRIBUTION TO THE SURGICAL TREATMENT OF MALIGNANT DISEASE OF THE BREAST.

BY ROBERT SANDERSON, M.B. OXON., M.R.C.S. ENG.,
LATE DEMONSTRATOR OF ANATOMY, WESTMINSTER HOSPITAL MEDICAL SCHOOL; SURGEON TO THE WOMEN'S HOSPITAL, BRIGHTON.

THE published statistics of the results of the surgical treatment of malignant disease of the breast so plainly show disappointing results that little apology seems to be demanded for an attempt either to criticise the past or make suggestions for the future. It has become an acknowledged principle of the treatment that not only should the whole affected mamma

Digitized by Google

be freely and thoroughly excised, but that in addition a clean sweep should be made of its lymphatic connexions. It is unnecessary in this article to enumerate the pathological considerations which have led to the adoption of this principle, but it is very necessary to examine the question as to how far the principle has been applied to the practice now employed.

First, as regards anatomy. It is a matter of fact that efferent lymphatic vessels run from the axillary glands through the apex of the axilla into the posterior triangle, and after forming connexions with the glands therein finally enter the thoracic duct on the left side and the right thoracic duct on the right side. Moreover, superficial lymphatics from the skin covering the mamma track up over the clavicle to these same glands in the posterior triangle.

Now, to examine the practice. It is laid down that in primary malignant disease of the breast the axilla should be cleared out (after removal of the breast), whether the glands be visibly infected or not. Why? Because the fact that they are not affected macroscopically is no proof that they are not affected microscopically. And yet, in the face of the anatomical facts quoted above, it is not the usual custom or practice to go further. If it is wrong to assume that the axilla is free from disease because it shows no sign to the naked eye or finger, it is equally wrong to assume that the posterior triangle has escaped. If it is right and peremptory to clear the axilla, it is also right and peremptory to clear the posterior triangle. Still more is it inconceivable how the triangle can be left untouched if the axillary glands are found to be clearly affected at the time of operation.

It may possibly be objected that it is not feasible or is difficult to clear the posterior triangle. To this it can be replied that by a flap operation done a week or ten days after the primary operation a clean dissection can be made of the whole posterior triangle, that it is not difficult, and that it is quite feasible. A flap formed by a long incision down the sterno-mastoid muscle meeting an incision along the clavicle is detached as far back as the anterior border of the trapezius; this exposes the triangle, and the contents can be systematically removed with a little care and patience. By such means the acknowleged principle would be carried out as far as is possible, and if the principle is right it seems incumbent upon the surgeon to strive to apply it thoroughly in practice and not to be content with stopping half-way. It is not suggested that this is the best method of operating, and inasmuch as two cases only have been so treated, and those comparatively recently, no results of value can be produced. It is hoped, however, that this article will serve to ventilate the question as well as to point out that at present the practice appears to directly clash with the acknowledged principle.

Brighton.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—A meeting of the British Medical Temperance Association was held on Wednesday, Dec. 11th, at the London Temperance Hospital, when a paper was read by Dr. C. R. Drysdale on Therapeutics without Alcohol, in which he contended that alcohol was of little, if any, use in the treatment of disease. Sir B. W. Richardson, who presided, said that, in conjunction with the late Dr. Farr, he had found that more people were killed by alcohol than by phthisis. The discussion was continued by Dr. Norman Kerr, Mr. Hazel, Dr. Paramore, and Dr. Ridge, and a vote of thanks was accorded to Dr. Drysdale.

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY. The December meeting was held at the infirmary of St. George's-in-the-East on the 14th inst., Mr. J. R. Lunn being in the chair. Dr. M. M. Bowlan (medical superintendent of St. George's-in-the-East) exhibited cases of Extensive Ulceration of both Feet; Suppuration of Knee-joint cured and perfect movement regained by draining and free irrigation; Congenital Heart Disease; Pityriasis Rubra; and Jaundice associated with Rupial Eruption. The question of a uniform diet for all workhouses within the metropolitan area was discussed and approved of, Mr. Walter Burney (Greenwich) pointing out that those houses which adopted a more liberal diet were favoured with the company of the professional workhouse loafer, who was a pest to society and made these institutions unendurable to the respectable poor. Various other administrative matters were discussed, and a vote of thanks to Dr. Bowlan for his interesting series of cases terminated the proceedings.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

ACUTE PERFORATION OF AN ULCER OF THE STOMACH; LAPAROTOMY; RECOVERY.

(Under the care of Dr. W. PASTEUR and Mr. HENRY MORRIS.)

THIS case makes the eighth record of operation for perforation of simple ulcer of the stomach that we have published in the Mirror of Hospital Practice during the course of the present year. It was, however, the first of the series to be subjected to operation, and has probably been already referred to, although not previously published. It is a very important case, because it shows distinctly the local symptoms which may be present soon after perforation has taken place, at the stage, in fact, when morphia is so often given and much valuable time lost in consequence of the masking of symptoms which that drug produces. The absence of rigidity of the abdominal muscles when the girl was first seen, although there was already a loss of the liver dulness, should be especially noted; it was not long before this rigidity or "guard action" was found, but that it may be absent at first is an important observation. In the seven other cases referred to life was saved by operation in four cases, and in a fifth it was prolonged until the eleventh day. In all but one the perforation was of an ulcer on the anterior surface of the stomach. The fact which comes out most prominently in these records is the importance of early operation. The successful results were gained when there had been intervals of six, nine, nine, and thirteen and a half hours between the first symptoms and the operation, and death ensued when the intervals had been fourteen, nineteen, and niceteen and a half hours. This is a most striking fact, more strongly emphasised as the patient who only lived for ten days was the one operated on fourteen hours after the commencement of the symptoms. In the larger number it was possible to suture the opening in the stomach, but in one the tissues around the opening gave way, and it was necessary to excise the edges in order to reach healthy parts for the sutures. In one case a tube was passed into the stomach through the opening. For the notes of this case we are indebted to Mr. W. E. Hudleston, house surgeon, and Mr. John Murray, surgical registrar.

A young woman aged twenty-four years, single, presented herself at the out-patient department of the Middlesex Hospital on March 10th, 1894, at 3.30 P.M. She had enjoyed good health until two years ago, when she became subject to indigestion, which, however, had only given trouble during the preceding six months. The chief symptom was epigastric pain very soon after taking food and lasting for some two hours. During the previous three months there had also been sickness after food, sometimes on several successive days, and for the last six or eight weeks the patient had not touched meat or potatoes on account of the pain which followed. On one occasion, some four months previously, she vomited a small quantity of dark blood. The bowels had never given her any trouble. She had been under treatment for dyspepsia during the last few weeks. The patient was in her usual health on the morning of the 10th, and took boiled haddock at her midday meal (12.30). At 2.30 p.m., as she was hurrying upstairs, she was suddenly seized by a strong "drawing" pain in the lower abdomen. This rapidly increased in area and intensity, and by the time she reached the hospital, an hour later, had spread over the whole abdomen. She managed to walk to the hospital, about a quarter of a mile, but was doubled up with pain and felt faint. There was no vomiting. Her appearance when first seen did not in any way suggest the nature of her illness. As she lay on a couch in the out-patient room, with slightly flushed cheeks, without pinching of features or anxiety of expression, answering

Digitized by Google

questions readily in a clear voice, there was little to suggest acute perforation of the stomach. Physical examination of the abdomen, however, left little room for doubt as to the true state of things. There was slight uniform distension of the abdomen; the abdominal wall was quite flaccid, and gentle palpation could be borne without much pain The percussion note was everywhere tympanitic and the liver dulness was completely obliterated. The patient was at once removed to the wards, and when seen again an hour later her condition had already changed considerably for the worse. The face was now anxious and somewhat pinched, the abdominal wall had become rigid and acutely tender, the girth at the umbilicus was greater since admission by more than one inch, and pain was rapidly becoming more acute. At 6.30 P.M.—just four hours after the first onset of symptoms—Mr. Henry Morris operated. A median incision four inches long was carried from the costal angle towards the umbilicus. After dividing the superficial structures the peritoneum bulged up into the wound, and on being nicked allowed a quantity of offensive gas to escape. When the peritoneum was divided the distended colon presented in the wound. This was returned into the cavity, flat sponges were introduced, and the wound enlarged downwards to the umbilicus. On drawing the stomach up into the wound a perforation the size of a No. 12 catheter was brought into view. It was situated close to the pylorus on the anterior surface near the greater curvature. The ulcerated portion of the stomach was invaginated by means of eight Lembert sutures of No 2 silk, a second row of sutures being placed more superficially to strengthen them. The peritoneum was thoroughly irrigated with a 1 in 400 carbolic solution at 105° F., and the pelvis sponged out as dry as possible. The various peritoneal pouches were similarly dealt with. Much lymph was removed from the surface of the liver. The abdominal wound was closed with nine thick silk sutures, and the ordinary dressing applied. During the irrigation of the peritoneum the pupils became widely dilated, and there was a tendency to failure of respiration. Much difficulty was experienced in maintaining respiration for an hour or two after the operation. At 9.30 P.M. breathing was of the Cheyne-Stokes type, the pulse had improved considerably, and the temperature was 93°. On March 11th the patient had slept five hours and a half during the night. She complained of pain on respiration. There was no sickness. The temperature was 99·8°. She was ordered to take nothing whatever by the mouth; a morphia suppository was to be repeated if necessary, and a rectal tube to be passed frequently. On the night of March 11th the patient was sick twice and again four times on March 12th. The vomit was watery and bile-stained, but contained no blood. At 4 P.M. she was ordered one teaspoonful of hot water every hour. The pulse was 116, the temperature 99·6°, and the respiration 26. On March 13th there had been no more sickness. She was ordered two teaspoonfuls of hot tea and milk every hour. On March 14th a simple enema was administered. Her diet consisted of six ounces of tea and twelve ounces of hot water in the twenty-four hours. Nutrient enemata were ordered to be given every four hours. On March 15th urine was passed naturally for the first time. One teaspoonful of prepared meat juice every two hours was ordered. On March 18th the patient was improving steadily. The stitches were removed on this day. Two ounces of arrowroot every five hours were ordered. On March 22nd progress was uninterrupted. There was some distension, which was relieved by a rectal tube. On March 24th the wound was nearly healed. The patient left the hospital cured on April 7th. She came again to the out-patient department more than twelve months after the operation complaining of pain after food, which rapidly yielded to simple remedies. She stated that she had been perfectly well and strong ever since leaving the hospital.

Remarks by Dr. PASTEUR.—This case illustrates many points which have been emphasised by subsequent experience. The early recognition of the nature of the case and the prompt resort to operative procedure doubtless contributed in no small measure to the recovery of the patient. The diagnosis was made within one hour of the onset of symptoms, and before five hours had elapsed the perforation had been closed and the peritoneum thoroughly cleansed. The importance of an early diagnosis is self-evident, and with increasing knowledge of these cases this should become more and more easy of attainment. The value of "obliteration of the liver dulness" in this instance was manifest. Had this not been recognised when the patient was first seen the difficulty in making a diagnosis would have been much greater. The history and the mode of onset were, it is true, suggestive of the true cause; but in view of the complete absence of the pinched look of the face, of the tense, tender abdomen wall, and of all signs of general collapse, one might well have hesitated to give an opinion on the spot and felt disposed to watch the case awhile before making a definite diagnosis. I am doubtful, however, whether delay, even in such circumstances, could be justified. Personally, if in doubt at the outset of a case of this kind I would rather urge a patient to run the comparatively trifling risk of an exploratory incision than allow the time to pass by when an operation might have cured an otherwise necessarily fatal accident. Two other factors also doubtless contributed to the favourable result—the one, the good general condition of the patient, and the other the almost complete absence of the initial collapse which is so often met with in these cases. This last is probably a point of considerable importance in estimating the chances of success in any given case.

CHRISTCHURCH HOSPITAL, NEW ZEALAND.

INTERESTING SURGICAL CASES IN THE WARDS.

(Under the care of Dr. COURTNEY NEDWILL.)

WE are pleased to be able to bring before the readers of THE LANCET the notes of the following cases of successful surgery in the hospital of Christchurch. Hydatid disease is very common in the colony of New Zealand, and cysts have been met with in all the various internal organs. We can only suppose that the thyroid has escaped implication to the extent shown by Dr. Nedwill because of its comparatively small size. With regard to the size of stones which have been removed from the bladder by the suprapubic route during the life of the patient, we published in THE LANCET the account of a case under the care of Mr. Milton,[1] who extracted a stone, now in the museum of the Royal College of Surgeons of England, which weighed thirty-four and a half ounces by suprapubic cystotomy from the bladder of a fellah aged sixty. The man lived two months and a half and then died from kidney disease. Even this is exceeded by the case referred to in Ashhurst's "International Encyclopædia of Surgery," of which we have been recently reminded by Sir G. M. Humphry,[2] where a surgeon removed a stone weighing forty ounces and a half. The man did not survive more than eight days. It is to be expected that extraction of the larger stones should be more frequently followed by a fatal result, as their long sojourn in the bladder will have caused more extensive changes in the kidneys. When small ovarian tumours are attached by long pedicles they are difficult to diagnose from movable kidney, wandering spleen, and tumours of the omentum or intestine, or uterus. When larger, and there is likewise a considerable amount of free fluid in the peritoneal cavity, difficulty arises in another way, as it is often quite impossible to determine the exact nature of the growth, whether it is cystic or solid, &c., and the only way to make certain is to perform abdominal section. Those experienced in abdominal examinations can frequently make a shrewd guess, but short of operation there is little to help in the diagnosis between a moderate-sized sarcoma of the ovary, with multiple growths in the peritoneum, and a multilocular ovarian tumour of similar size one of the cysts of which has been slowly filling the peritoneal cavity with fluid after its unnoticed rupture.

CASE 1. *Hydatid cyst of the thyroid gland.*—A girl eight years old was admitted on July 1st, 1895, on account of a tumour occupying the central part of the thyroid gland. Her mother said she first noticed a lump in her child's throat about three years previously. During the last three months the child had had great difficulty in breathing, especially at night, frequently starting up in bed, throwing her hands about, and appearing as if she would be suffocated. After her admission she had several severe attacks of dyspnœa. On July 3rd she was placed on the operating table and an attempt made to anæsthetise her which had to be abandoned

[1] THE LANCET, Sept. 16th, 1893.
[2] THE LANCET Nov. 30th, 1895, p. 1342.

Digitized by Google

on account of impending suffocation. A hypodermic injection of cocaine was then made over the tumour, which was easily exposed by a short vertical incision. The pearly-white appearance of the cyst and the clear fluid drained off when it was incised suggested its nature. The lining membrane was removed by forceps and the edges of the opening in the cyst were stitched to the skin wound. On introducing the finger into the cyst it was found that it had insinuated itself all round the trachea. On July 29th she was discharged with only a very small sinus remaining unhealed.

Remarks by Dr. NEDWILL.—I can find only one other similar case reported—namely, by Wilks and Moxon—and as there was no mention of hydatids either by Mr. Butlin or the other members of the British Medical Association who recently discussed the subject of tumours and cysts of the thyroid gland, I take it that this case is of sufficient rarity to justify its publication.

CASE 2. *Large vesical calculus weighing only ten grains short of eleven ounces removed by supra-pubic operation.*—A man aged thirty-two was admitted to the hospital on June 3rd, 1895. Ever since he was fifteen he had suffered great pain and had had difficulty in passing urine. For the previous three years he had been quite unfit for work. On examination a very large stone was detected. The urine was very offensive and highly albuminous. The bladder was frequently washed out for a few days, and on the 9th, six ounces of boracic solution having been injected and a rectum bag introduced, the abdomen was opened above the pubes. The greatest difficulty was experienced in extracting the stone; the wound had to be enlarged, not only close up to the pubes, but upwards in the direction of the peritoneum. To prevent extravasation Dr. Nedwill had to insert fourteen or fifteen catgut sutures between the cut edges of the bladder and the abdominal wound. A drainage-tube was passed into the bladder, and irrigation was carried out sometimes twice, thrice, or four times during the twenty-four hours. On July 1st urine was passed for the first time from the urethra. During this month the patient had several rigors with high temperature—on one occasion a temperature of 106° F. was recorded. After July 1st urine ceased to come from the urethra till the 27th. These rises of temperature were apparently due to some small pocketing of pus between the bladder and the abdominal wall, as from first to last there was no extravasation of urine. On Aug. 1st the temperature was normal. On the 23rd a dry dressing was applied. On Sept. 7th it was reported that the patient sat up every day and the wound was healed. He was discharged on the 15th in excellent health.

Remarks by Dr. NEDWILL.—I am much indebted to Dr. Graham Campbell, who was acting for Mr. Murray-Aynsley, our house surgeon at this time, for the great care he gave this case during the after-treatment. Quite twenty grains extra were chipped off the stone during extraction. I have not the advantage of consulting a reference library, and cannot, therefore, say whether other stones larger than this one have been successfully operated for. A short time ago I read a report of a lecture by Mr. Christopher Heath, where it was mentioned that he had removed a stone of a similar size. Mr. Heath stated in his lecture that he had never had a more sultry Sunday afternoon's work than in removing it. In my case I can also say I never had a more sultry Sunday morning's work.

CASE 3. *Fibrous tumour of the ovary with a very long and narrow pedicle.*—A married woman aged forty-nine was admitted to the hospital on June 5th, 1895. She had been confined of her last child in 1877 and had, she said, inflammation of the bowels at that time as well as ten years previously to admission. The abdomen had been gradually enlarging since her confinement, but more especially during the previous twelve months. On her admission the abdomen was found to be very much distended with fluid, which was evidently in the peritoneal cavity. A tumour could be felt floating in this fluid and easily tilted far away from the finger in any direction. On the 9th the abdomen was opened; about two gallons of peritoneal fluid were removed, and a solid tumour weighing 1 lb. 8 oz., with a very long and narrow pedicle, was easily extracted. Only a few omental adhesions were present, and a single ligature was found sufficient for the small pedicle. The temperature remained normal throughout the after-treatment, and she was discharged on July 13th.

Remarks by Dr. NEDWILL.—Mr. Murray-Aynsley examined the tumour for me and reported it to be an almost pure fibroma with a minute cyst in its substance. I report the case as I understand it to be not very common.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Adjourned Discussion on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues, as in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, &c.

(Concluded from p. 1501)

Mr. SPENCER WATSON said that in syphilis the persistence of glandular enlargement would lead to a suspicion that the disease was latent, and that therefore treatment should be prolonged. The virus of both pathogenic and non-pathogenic bacteria could be attenuated by sunlight, and something like this might happen in the case of patients who were sent to a sunny climate, though in the latter case the benefit resulted rather from increasing the resistance of the tissues of the patient.

Dr. LAZARUS-BARLOW said that he proposed to deal with the bacteriological aspect of the question, and with only one section of it. In pébrine the silkworm's egg after being laid was seen to contain germs of microbes. These would remain latent in the egg during the winter, although the temperature might be favourable to their development. When the egg began to germinate then the microbes increased in number until the caterpillar was fully developed. This fact illustrated that there was a certain something essential to the development of the microbe and which depended upon its environment. He, some time ago, came across a paper[1] in which was discussed a question whether plants could absorb nitrogen from the atmosphere when nitrogen was not presented to them in the soil. Two seeds were sown under these conditions; they put forth leaves which were green and turgid, but a total arrest of growth ensued for over two months. The arrest or growth of a plant or organism depended chiefly upon the conditions under which it found itself. The influence of environment was especially well seen in the case of the diphtheria bacillus, which was so fastidious as to require a certain particular amount of alkali in the culture medium. If the diphtheria bacillus were grown upon Lorrain Smith's serum, which consisted of sterilised blood serum plus alkali, the question whether growth started depended upon the length of time the serum had been sterilised and upon its non-exposure to atmospheric air. It was upon the culture medium that latency depended. In London all were probably almost equally exposed to infection with the tubercle bacillus. A would become infected and B not; this depended rather upon peculiarities of A and B than on the organism.

Dr. THEODORE WILLIAMS said that he found difficulty in distinguishing between latency and arrest in tuberculosis. By latency appeared to be meant the condition in which the virus was dormant, in arrest the virus might be dead. When could a case of tuberculosis be said to be arrested? He quoted the case of a man aged twenty-two years who was the subject of pulmonary tuberculosis, there being cavities in both lungs. Under favourable treatment the patient gradually recovered and became a short-breathed, stout man. Thirty-six years from the onset of the first symptom of phthisis, and sixteen from the last phthisical symptom, the patient died from non-tuberculous albuminuria, and at the necropsy the remains of a cavity were found in one lung surrounded by fibrosis, and in the other were the remains of a cavity together with a considerable mass of caseous material encapsuled by fibrous tissue. If this capsule had given way the patient might have died from miliary tuberculosis or from acute meningitis. One might truly say, call no man a case of arrested tuberculosis until he was dead. He referred to the following instances of tuberculous outbreaks after a period of latency: (1) a case of old pulmonary lesion which was quiescent was followed by acute head symptoms and death from tuberculous meningitis; (2) a patient with a cavity in the lung surrounded

[1] Annales de Chimie, 1855.

Digitized by Google

by fibrosis was placed under unfavourable hygienic circumstances and then tuberculosis developed at the opposite pulmonary apex; (3) tuberculous meningitis suddenly developed after old tuberculous osteitis of the vertebræ; and (4) tuberculous lymphadenitis of the neck, axilla, or elsewhere, remained quiescent, then a gland suppurating started acute miliary tubercle of the lung or tuberculous meningitis. The mediastinal and bronchial glands were especially apt to be invaded with tubercle after scarlet fever. There was danger following sometimes upon operation on chronic tuberculous lesions, and he referred to a case in which scraping of an axillary lymphadenitis was followed within forty-eight hours by the development of tuberculous meningitis elsewhere. He had met with a case of tuberculous pericarditis which followed upon an old lesion.

Sir WILLIAM BROADBENT said that in his opinion the papers had almost exhausted the subject, and very little room was left for the addition of new facts. The point of main interest to the society was to see that clinical cases could be explained by experimental investigation. He quoted a case in which a fall from a horse was followed by the development of acute tuberculosis. Latency might result from the encapsulation of the bacilli or their spores, or it might depend upon other circumstances in the environment. He had met with many cases in which the cause of typhoid fever could not be traced to any known cause during the usually observed period of latency or incubation. Cold or influenza frequently opened the door to typhoid fever by diminishing the tissue resistance of the individual; this was paralleled by experiments in animals. Injection of micro-organisms up to a certain dose might be followed by no infection, but if a non-infective dose were injected on one side and a dose of chloral were injected at the same time on the opposite side the animal would succumb. A somewhat similar state of affairs probably existed in the cases of scarlet fever following operation.

Dr. MANSON said that the causes of latency of disease and the conditions under which organisms became latent were various. In malaria the action of quinine did not kill the organism, but reduced its malignancy; warmth and good food acted in a similar way. The latency of the organism might be, so to speak, broken up by the action of adverse influences. A patient treated successfully for malaria in India when coming home might encounter bad weather in the English Channel; this would induce a fresh attack of malaria. The fungus which induced a particular form of itch in the tropics remained latent in the cold weather. Purely mechanical conditions of the parasite might induce symptoms, as when the filaria became rolled up and thus blocked the thoracic duct.

Mr. J. HUTCHINSON, jun., said that undoubtedly a few cases of syphilis, a very few, occurred in which the poison of the primary chancre remained latent for much over the usual period of time. Of this, one of the strongest examples was a patient at the Lock Hospital who was exposed to risk on Aug. 17th, a fortnight after which he came for an indolent inguinal bubo. The most careful search failed to discover any initial sore. He was again thoroughly examined on Aug. 31st, Sept. 17th, and Sept. 22nd, with the same result, no mercurial treatment being given. It was not till Oct. 5th—i.e., seven weeks after the solitary exposure to contagion—that an indurated ulcer developed close to the frænum, the bubo meanwhile having become still more characteristic. Secondary symptoms followed in due course. Such a case would make one less sceptical as to the tales of syphilitic "bubon d'emblée" in the male subject. It was possibly from prison surgeons and hospital physicians that the least doubtful evidence as to latency of primary syphilitic germs would be obtained. Aimé Martin observed the development of a hard chancre on the labium of a girl who had been for ten weeks isolated in the prison of St. Lazare. And as regarded the onset of secondary syphilis he could most positively confirm M. Diday's observation that an intercurrent illness might postpone it very considerably. M. Diday mentions two cases (one of typhoid fever and the other of pneumonia) in which the primary chancre had been contracted previously to the illness, whilst secondary symptoms did not appear for 120 and 160 days respectively. In two similar cases in which the patient had contracted an indurated chancre before or whilst sickening with typhoid fever Mr. Hutchinson had observed the syphilis "hang fire" until complete recovery had taken place from the typhoid fever—i.e., a period of from three to four months. As to the latency of tertiary symptoms the facts were too well known to require emphasis. For example, in a case he had published a man contracted syphilis at the age of twenty-one years, and after going through the ordinary secondary symptoms remained wholly free until the age of fifty-three years, when exposure to much privation was followed by the outbreak of multiple nodes of the skull, ischium, and humerus. Similar instances of long apparent latency were common both in acquired and inherited syphilis, and pointed to fresh activity of organisms which had remained in the tissues, though unfortunately the bacteriologist could not at present furnish any proof. Allusion was made in Mr. Lane's paper to the immunity from fresh infection or auto-inoculation during the primary stage. A remarkable exception occurred last year. A man under treatment with a hard chancre of the penis and inguinal bubo after six weeks inoculated one finger by accident, developed a chancre at this site, followed by swollen, hard, lymphatics up the arm, and large axillary glandular swelling. The patient had particularly severe secondary symptoms.

Dr. GEORGE OGILVIE said that Colles's law if valid established only the immunity of the mother, and did not justify the inference of latency. That a person was immune against syphilis no more proved that syphilis was latent in him than would a similar immunity against typhoid fever or tetanus. The term immunity had been used in two senses—as "refractory" and as "free from symptoms"; the latter was latency. He failed to grasp the distinction between "real" and "apparent" latency which the President had drawn. The term "latency" he took to mean a symptomless interval between two manifestations of disease, the second manifestation being either a clinical one or a discovery at the post-mortem table. Diseases which were non-specific, and which occurred in people who had had syphilis, were commonly called syphilitic, and this extended artificially the period of latency. Very little had been said as to the part which irritation, traumatism, or puberty played as disturbers of latency, and he quoted a case in which interstitial keratitis was evoked by traumatism. Paralysis of the limbs in late hereditary syphilis had frequently a blow for an exciting cause. In late hereditary syphilis two, five, ten, or twenty years might elapse before external manifestations were recognised, though internally the malady had existed in foci from the time of birth.

Dr. J. EDWARD SQUIRE said that the disease tuberculosis might lie latent for long, but the question was whether the germs remained latent also. Perhaps the bacilli were really active within an encapsuled focus, and doing as much damage as they could do in the confined space.

Dr. W. K. SIBLEY thought that the latency of a germ resembled the hibernation of an animal, and he referred to his published experiments upon the induction of tuberculosis in snakes, the disease progressing rapidly when the snakes were incubated, and becoming arrested when the reptiles were kept at an ordinary temperature. He suggested that experiments might be made with such an animal as the dormouse to see if tuberculosis would remain latent during the hibernation of the animal.

Dr. J. A. HAYWARD referred to a case which he had already published. A child was suffering from diphtheria and recovering, he was then attacked with measles, and at the invasion of measles there was a renewed activity of the diphtheria bacillus with a re-formation of membrane.

Mr. HUTCHINSON, in reply, explained that by "real" latency was meant absolute quiescence of the infective agent, whereas if the germ were doing something in the body he regarded this as "apparent" latency.

Dr. WASHBOURN and Dr. KINGSTON FOWLER also briefly replied.

PATHOLOGICAL SOCIETY OF LONDON.

The Varieties of Diphtheria Bacilli.—The Xerosis Bacillus.—Exhibition of Specimens.

AN ordinary meeting of this society was held on Dec. 17th, Mr. ALBAN DORAN, Vice-President, being in the chair.

Mr. E. A. PETERS read a paper on the Varieties of Diphtheria Bacilli, in which he described four kinds of bacilli. The following is a summary of points of difference seen in early cultivations. 1. Long Klebs-Löffler bacillus. A twenty-four-hour cultivation on blood serum showed short bacilli, long segmented forms 0·003 mm. in length, long clubbed bacilli, and short clubs. This bacillus was pathogenic to guinea-pigs, and did not readily lose this property. 2. Short diphtheria bacillus (described in detail for the first time). This bacillus when compared under the same conditions

Digitized by Google

with the long Klebs-Löffler bacillus differed from it in that at twenty-four hours' culture it consisted of a large number of conical bacilli 0·0015 mm. in length, with a few slightly segmented forms, which were characterised, as were also the short forms, by a pointed sheath. This bacillus was pathogenic to guinea-pigs, but soon lost this character. 3. The short pseudo-diphtheria bacillus under the same conditions showed numerous forms 0·001 mm. in length. Segmented forms were short and rare with this bacillus. The bacillus was never pathogenic to guinea-pigs. 4. Bacilli resembling the long Klebs-Löffler bacillus, except for slight clubbing and more definite segmentation. These were non-pathogenic to guinea-pigs. The clinical aspects of the cases in which these bacilli were found were: 1. The long Klebs-Löffler bacillus was found in cases of severe diphtheria. 2. The short diphtheria bacillus, which was less common, was associated with mild cases of diphtheria. 3. The short pseudo-diphtheria bacillus was widespread and was found in many cases of follicular tonsillitis, in cases of scarlet fever, rötheln, simple angina, and other catarrhal conditions. The affection with this bacillus *per se* was never fatal. Accordingly the importance of the differentiation of these bacilli, which was possible with cultivations on blood serum after twenty-four hours' exposure to a temperature of 37° C., was urged. 4. These bacilli caused no apparent hurt and were possibly non-pathogenic forms of the long Klebs-Löffler bacillus. Experiments principally by cultivation methods had been made by Mr. Peters for over a year with a view to the possible change of one variety into another, with the result that no such change was recognised. No. 2, however, readily lost its virulence to guinea-pigs. (Dr. Washbourn carried out the inoculation experiments.) It seemed probable that these bacilli were allied forms, while their morphological characters and clinical significance warranted the separation of these four varieties. The paper was illustrated by lantern slides prepared by Mr. Bousfield and also by cultures and microscopical specimens.

Mr. J. EYRE read a paper on Neisser's Xerosis Bacillus, commenting upon its close resemblance to the bacillus diphtheriæ. He had isolated it from the conjunctival secretion of a series of cases which presented slightly different appearances from the ordinary form of follicular conjunctivitis, and which appeared to be somewhat infectious; also from one case of trachoma, but he had been unable to detect it in the secretion from normal conjunctivæ. The cultural and morphological appearances upon various media were described and the differences between it and the Klebs-Löffler bacillus pointed out. The chief points to be relied upon in differentiating the xerosis bacillus from the bacillus diphtheriæ were summed up as follows: (1) first cultures from the conjunctival secretion, &c., did not make their appearance under thirty-six to forty-eight hours; (2) the production of an alkaline (never an acid) reaction in broth and milk; (3) retarded and scanty growth on gelatin—poor growth and rapid death upon potato; (4) the invariably innocuous character of the broth cultures when inoculated into animals susceptible to the bacillus diphtheriæ; and (5) the transition to a short, straight bacillus staining evenly after cultivation on blood serum for ten to fifteen generations, and the restoration of those characters which render it liable to be mistaken for the diphtheria bacillus when transplanted on to glycerine blood serum.

Mr. LENNOX BROWNE said that the photographs shown by Mr. Eyre disturbed his faith in the specificity of the diphtheria bacillus, for the organisms he had shown would certainly have been diagnosed microscopically as diphtheria bacilli. The diagrams which Mr. Peters had shown bore no resemblance to the photographs. He thought it important that bacteriologists should agree on a culture medium upon which the bacilli to be diagnosed should be grown, as very different results were obtained by growing the same organism on different media, and this tended to introduce confusion. He had seen an exceptionally mild case of diphtheria associated with the long bacillus, and an exceptionally severe case associated with the short bacillus, and he had found the pseudo-bacillus associated with ordinary tonsillitis. He had found streptococci, staphylococci, and diplococci (but not pseudo-bacilli) associated with cases which had taken the clinical course of diphtheria. In the last photograph Mr. Peters had shown he saw several staphylococci associated with the diphtheria bacillus.

Dr. WASHBOURN traced the history of diphtheria bacilli. What Löffler first described was a long bacillus which was pathogenic. Then Hoffmann described a short bacillus which he called the pseudo-diphtheria bacillus, which was non-pathogenic and was found under a number of conditions other than diphtheria. Roux and Yersin later contributed a paper[1] dealing with the biology of diphtheria bacilli and their relation to the pseudo-diphtheria bacillus. They found that the non-virulent forms were morphologically identical with the virulent forms. Mr. Peters had demonstrated a bacillus which differed morphologically from the diphtheria bacillus and which was found in diphtheria and other conditions. It always retained its cultural and morphological characters for those particular media respectively on which it was grown. It had been found in the throat in German measles, also in scarlet fever with a mild throat affection which was non-diphtheritic, and in another case of scarlet fever associated with nasal discharge, also not diphtheritic. Mr. Peters had described two varieties of diphtheria bacillus; a long bacillus which was either pathogenic or non-pathogenic and a short bacillus which differed in morphological particulars from the long bacillus which was pathogenic, but the virulence of which disappeared after long culture. Roux and Yersin had described both the long and the short bacilli as non-pathogenic. Those acquainted with the bacteriology of the microbe they were working with were quite familiar with the appearance of the organism on each of the respective media. The short bacillus grown in broth would become shorter, and the pseudo-diphtheria bacillus when grown on blood-serum would become longer; this showed how important it was to know exactly the nature of the culture medium from which the specimen had been obtained. He was satisfied that all Mr. Peters's preparations were from pure cultures and that there was no contamination of them with staphylococci.

Dr. KANTHACK thought that the confusion already existing had been rendered worse by Mr. Peters and Dr. Washbourn. Two forms of bacillus had been described as pseudo-diphtheria bacillus, one of which was morphologically like the true diphtheria bacillus, while the other was quite different. He thought that the term pseudo-diphtheria bacillus ought to be given up altogether. There was at present only one test which could be applied to decide whether a particular organism was pathogenic or not, and that was to discover its virulence when inoculated into animals. In cases which were not those of diphtheria bacilli had been found by him, and these when inoculated into a guinea-pig killed it in twelve or even ten hours. At St. Bartholomew's Hospital he had made 195 examinations, mostly on very virulent cases, and he found that he could not argue from the length of the bacilli or from their clubbing whether they were virulent or not. It was easy by cultivation to change the long form into the short form, and both long and short bacilli were to be found in nearly all colonies on the surface of agar; he had never found unmixed colonies of the long variety. He had occasionally seen the short variety change into the long variety. He concluded by asserting that any morbid lesion in a throat which was associated with the Klebs-Löffler bacillus was a case of diphtheria; that culturally, tinctorially, and morphologically these might resemble other non-pathogenic bacteria, and that they could not be identified without experiments on animals. With regard to the xerosis bacillus he had made examinations of a series of cases of conjunctivitis. From two cases, which were those of ordinary muco-purulent ophthalmia, he cultivated a bacillus on serum and agar-agar, which was morphologically identical with the diphtheria bacillus. In two cases of membrane upon the conjunctiva following traumatism, one from a burn with lime and one from a burn with nitrate of silver, similar bacilli were present. But the gelatin culture of this organism was different from that of the diphtheria bacillus; it grew in small colonies which were not dead-white like those of the diphtheria bacillus; the agar culture was also different. Non-pathogenic long bacilli resembling the long form of diphtheria bacillus had been found in bad meat and in cow's milk by Klein. There were, indeed, a large number of bacilli which conformed to this type, and this emphasised the small reliance to be placed on morphological identity.

Dr. H. DURHAM disputed the value of experiments on animals to determine the virulence of the organism under examination, and quoted Koch's experiments in this direction with cholera bacilli, which were absolutely worthless in identifying the microbe of cholera. What was required was to prove absolutely, by means as yet unknown, that the

[1] Annales de l'Institut Pasteur.

Digitized by Google

so-called pseudo-diphtheria bacillus could be raised in virulence.

Dr. GOODALL asked how many times the cases were examined before the organism was pronounced to be a pseudo-bacillus. Some of his patients had been examined twice and the bacillus of diphtheria had not been found, and yet the patients had afterwards developed paralysis. The long variety he had found to be always present in the severe cases, while the short variety he had not found by itself in cases which were really bad or in which paralysis had afterwards developed. He hoped the term pseudo-diphtheria bacillus would be discarded.

Mr. PETERS, in reply, pointed out that a bacteriological examination was often valueless unless material were taken directly from the larynx. His pseudo-diphtheria bacillus he had seen cause membrane in but one instance. The pointed bacillus, which was rare, was the one which, being pathogenic, most resembled the short, non-pathogenic bacillus.

Mr. EYRE also briefly replied.

The following card specimens were shown:—

Dr. WEBER: Heart from case of Angina Pectoris.

Dr. SNOW: Colloid Carcinoma of Breast.

Mr. LENNOX BROWNE: Malignant Growths of Tonsil.

Dr. ROLLESTON: Crateriform Ulcer.

Dr. HUGH WALSHAM: Tuberculous Liver with Lardaceous Disease.

CLINICAL SOCIETY OF LONDON.

Membranous Colitis treated by Right Colotomy and subsequent Closure of the Wound.—Congenital Median Cervical Fistula.

AN ordinary meeting of this society was held on Dec. 13th, Dr. WHIPHAM, Vice-President, being in the chair.

Dr. HALE WHITE and Mr. GOLDING-BIRD communicated the particulars of a case of Membranous Colitis treated by Right Colotomy and subsequent Closure of the Wound. The patient, a neurotic woman aged thirty, first began to pass mucus from the rectum and to suffer from constipation in 1885. From that time both these symptoms had become more marked, and by 1891 she was suffering from severe abdominal pain. In the next year the motions often consisted of nothing but mucus and blood, and the pain was agonising. This state of things continued till 1894, when she began to pass tubular casts; the pain kept her in bed most of the day, very strong purgatives were necessary to move the bowels, and she was a complete invalid. When seen by Dr. Hale White and Mr. Golding-Bird in 1895 she was in the same condition and had much tenderness over the descending colon and sigmoid flexure. A motion was examined; it consisted of a little fæces, much mucus, long tubular casts, and a considerable amount of blood. As during the previous ten years all sorts of drugs, various diets, prolonged rest in bed, and many health resorts had been tried, it was decided, with the consent of Dr. Walter Smith of Dublin, to perform a right colotomy. The bowel was fixed to the surface on May 10th, and opened on May 17th. Three days later the colon was washed out from the artificial to the natural anus with hot water, but already the membranes had ceased to be formed. For five weeks all the motions were passed through the artificial anus without the aid of purgatives. The fæces always appeared normal. As at the end of this time all the original symptoms had disappeared, the colotomy wound was closed and the bowels were subsequently kept confined for a week with opium. Some compound liquorice powder was then given, and a motion which was passed contained neither mucus nor blood. The general health and strength improved, and she went into the country on July 24th, feeling better than she had done for many years, having passed no blood or mucus since the operation on May 10th. Dr. Hale White and Mr. Golding-Bird submitted that in a severe case of membranous colitis this treatment was justifiable and was the most rational, for by it the colon could have complete rest. Their patient, it was true, had since died, but as far as could be made out her death had nothing to do with her operation or the colitis. Her subsequent history was imperfect, but it could not be made out that she suffered from membranous colitis after she left London.—Mr. ADNEY (Tunbridge Wells) said that he witnessed the last forty hours of the life of this patient. When called to her he found that she had already acute general peritonitis which was equally marked on both sides of the abdomen. She was moribund, and the inflammation appeared to be of the suppurative form. The swelling felt per rectum was probably an enlarged lymphatic gland which had suppurated and the resulting abscess burst into the peritoneum. The patient stated that there had been no return of the symptoms pointing to colitis.—Mr. GODLEE said that the treatment of dysentery by colotomy had been suggested to him many years ago by Dr. Manson, but he had only had an opportunity of putting it in practice during the present year. The patient, a female, had suffered from dysentery in India, but the symptoms had passed off. Since her return home she had suffered from hepatic abscess which had burst into the bowel, and she had nearly lost her life from thrombosis after child-birth. The dysentery set in again and he did a left colotomy, his object being to apply nitrate of silver or other suitable local applications to the diseased bowel. The whole mucous membrane in the neighbourhood of the colotomy opening was studded with long polypoid growths an inch and a half or two inches in length. The patient somewhat improved after operation, but she died later from causes apart from the dysentery.—Dr. TURNEY said that between three and four years ago Mr. Ballance operated on a case which he had diagnosed as dysentery, but which turned out not to be so. The patient was a man aged thirty-five who had been in India but had not suffered from dysentery there. He complained of a discharge of blood and mucus from the bowel, and he was much emaciated. Mr. Ballance opened the abdomen in the right inguinal region, cut across the ileum near the ileo-cæcal valve, bringing the upper end of the gut to the surface and fixing it there to form an artificial anus, the lower end being also brought out for irrigation purposes. The gut was irrigated several times daily, the fluid traversing the whole length of the colon and escaping at the anus. The patient improved at first, but died from hypostatic pneumonia within a week. The ulcerated bowel readily absorbed the toxic products passing along it, although the mucous membrane was too diseased to perform any physiological function; hence it was no loss to the patient to be deprived of the use of the large intestine. He hoped this method of treatment would be extended to cases of ulcerative colitis. In the light of the case which had been narrated he was disposed to believe that in another case division of the intestine would be unnecessary.—Dr. F. HAWKINS (Reading) said that as membranous casts frequently came from parts of the bowel other than the colon he objected to the term "membranous colitis." He had seen cases in which casts had come from the jejunum and ileum. He thought a better name would be "mucous disease of the bowel." He believed that this affection was more common than was supposed, for he himself had met with several examples. In one case the patient, a woman aged forty-four, ceased to pass casts under purely medical treatment, and she had not passed any now for three years. She had been in the habit of taking large doses of sulphate of magnesia daily for a year before the trouble commenced, and another case had been reported in which the disease was preceded by the taking of large doses of this salt.—Mr. BARKER asked what was the microscopical structure of the casts and what was the mode of their production. In one case in which he made a microscopical examination of the casts they appeared quite structureless, containing only some scattered epithelial cells, the remainder of the casts appearing to consist merely of coagulated mucus.—Dr. HERRINGHAM said he was interested in the causation of this affection, among other reasons, because he himself had been a sufferer from it. The passage of casts usually followed a long period of constipation. He had examined many such casts under the microscope, and they were always structureless. If under treatment the constipation disappeared the membranes ceased to be formed. He knew of three cases which came to a sudden fatal termination, in all of which death was preceded by great pain and tenderness in the left side of the abdomen. In one of these cases which died after operation, and in another case which recovered after operation, an abscess was found in the region of the descending colon. With regard to the causation of these abscesses in the region of the sigmoid flexure, he thought they were due to retained fæces leading to ulceration. In one of the two cases of abscess he had referred to a small communication with the bowel was found, but in the other the pus was perfectly sweet, and as far as could be made out no communication existed with the gut. He added that a German physician who had described these cases under the name of "pericolitis

Digitized by Google

sinistra" believed them to be as common as suppurative lesions of the vermiform appendix.—Dr. SIDNEY PHILLIPS said that the subject under discussion was the treatment of colitis, and not that of dysentery; moreover, the mucous casts which were passed in cases of colitis were very different from those which were consequent on prolonged constipation. In colitis sloughs of mucous membrane were frequently passed, and the symptoms were different from those met with in association with dysentery. In colitis the ulceration often involved the small intestine as well, and this was a reason why, perhaps, the intestine should be opened in the lower ileum in preference to the colon.—Dr. WHIPHAM said that he had seen a case in consultation with Mr. Edgcombe Venning which was on all fours with the one related by Mr. Golding-Bird. The patient was a neurotic young woman who had passed mucous casts for some months before he saw her, and the passage of the casts was always preceded by attacks of severe pain in the region of the descending colon. Small doses of calomel secured free evacuation of the bowels, and the motions contained shreds and casts of mucous membrane. She was kept altogether in bed on a milk diet, and under this *régime* she became extremely emaciated, and it was feared that she would succumb, but although no change was made in the treatment she suddenly took a turn for the better, and for six months she had been quite well. A point of interest in connexion with this case was the fact that her sister had since manifested symptoms of the same affection.—Dr. HALE WHITE, in reply, said that he dissented altogether from what Dr. Hawkins had said in respect of the nomenclature, for the term "mucous disease" of the bowel was already applied to a different affection in children. He admitted that the disease might not be as rare as had been supposed, but it was certainly rare in a severe form. The mild form commonly followed constipation, and the patients usually got well when the constipation was relieved. This form was commoner in hysterical women. The severe form did not appear to be commoner in women than in men, nor was it commoner in neurotic subjects. With regard to the cases of abscesses in the left side of the abdomen, he had recently seen a case in which an elongated vermiform appendix led to an abscess which opened on the left side. With regard to the action of sulphate of magnesia as a causative agent, the patient did not go to Kissingen to take the waters until many years after the disease had been established. The microscopical appearances of these casts had been accurately and exhaustively described by Dr. Wilks and Dr. Goodhart in the Transactions of the Pathological Society.—Mr. GOLDING-BIRD, in reply, said that the local tenderness over the ascending colon led him to select that part of the gut for opening. It was remarkable that Mr. Godlee's patient was relieved by the operation although he did nothing to the papilliform excrescences on the mucous membrane. It should be borne in mind in respect of these cases that the mechanism of defecation when set in action in association with an ulcerated bowel excited profound nervous depression, and the opening of the gut in the region of the descending colon, by obviating this in a great measure, probably explained the relief experienced by Mr. Godlee's patient.

Mr. R. BARWELL related a case of Congenital Median Cervical Fistula in which operation was followed by recovery. The patient, a young woman, was sent to him in April last by Dr. Bezly Thorne with well-marked lateral curvature of the spine. On June 11th, her back being nearly straight, she showed an opening in the mid-line of the neck, situated on the most prominent point of the thyroid cartilage, which occasionally, at least once a day, discharged a thin fluid, and of which she was very anxious to be cured. The small orifice was surrounded by depressed and reddened skin for about a quarter of an inch from side to side; nearly half an inch from above downwards it was partially overhung by a transverse narrow fold of healthy skin. While the deeper parts of the throat were at rest the coloured depression was very shallow, but in swallowing it deepened, being drawn upward and inward, gliding under the transverse fold, which thus became more overhanging, widening also so as to stretch almost from one sterno-mastoid to the other. On palpation a line of cylindrical, somewhat hard tissue could be felt running up from the opening to the hyoid bone; it seemed about the size of a cedar pencil. The foramen cæcum was not abnormally large. She would not allow the use of a probe. He diagnosed a tubular remnant of a supra-hyoid accessory thyroid gland, and on June 19th he dissected it out through a small oval incision. The wound healed rapidly, though a re-collection of fluid had to be evacuated about a fortnight later. Unfortunately, no microscopical examination was made of the tube removed.

OPHTHALMOLOGICAL SOCIETY.

Retinitis Circinata.—A rare Form of Nystagmus.—Superficial Peripheral Choroiditis.—Embolism of the Central Retinal Artery.—Retro-bulbar Optic Neuritis.—Recurrent Paralysis of the Third Nerve with Migraine.—Double Ptosis.—Paralysis of both Internal Recti.—Exhibition of Cases and Card Specimens.

AN ordinary meeting of the above society was held on Dec. 12th, Mr. EDWARD NETTLESHIP being in the chair.

Mr. HARTRIDGE showed a case of Retinitis Circinata. It presented the appearance of a grey degeneration at the yellow spot, with a mass of white deposit in the nerve fibre layer of the retina radiating from the yellow spot region. There were no retinal hæmorrhages. It did not agree in every detail with the recognised appearances, but he thought it was possibly an early stage of retinitis circinata.—Mr. HOLMES SPICER thought that the characters of the white exudation in this case were more like those of albuminuric retinitis than of retinitis circinata. In all the undoubted cases that had been observed there had been a remarkable constancy in the character of the exudation, a grouping quite different from that shown in this case.—Mr. HARTRIDGE, in reply to Dr. HABERSHON, said that there was no renal disease; the heart had not been examined.

Dr. ERNEST CLARKE showed one case and Dr. GRIMSDALE three cases of Nystagmus in the fixing eye during occlusion of its fellow. In Dr. Clarke's case the vision in the two eyes together was $\frac{2}{3}$; when either eye was occluded by placing a card in front of it, the uncovered eye immediately began to oscillate violently. In Dr. Grimsdale's cases the nystagmus was of the same kind, but less marked.—Dr. HABERSHON said he had examined Dr. Clarke's case and found that, though there was no sign of actual nerve disease, the patient was of a neurotic type, and all the reflexes were more pronounced than usual.—Dr. ORMEROD pointed out that the patient was a jeweller and that the nystagmus had come on since he commenced that trade, in which he used a single watchmaker's glass to one eye.

A case of Peripheral Choroiditis of Obscure Origin was shown by Dr. RAYNER BATTEN. The patient was a woman aged forty. The choroiditis was limited to the periphery; the outline of the patches was irregular and map-like; the deeper layers were not affected, but the surface layers had a bleached appearance. Vision was almost unaffected except for slight contraction of the fields. No evidence of acquired syphilis could be found; the condition was probably a late manifestation of inherited syphilis. It was still progressing.—Mr. HOLMES SPICER thought the fundus changes in Dr. Batten's case were due to congenital syphilis, the white lines seen along the smaller veins being a common feature of that affection, and were also an indication of recent progress.

Mr. MARCUS GUNN related the case of a young adult anæmic girl in whom Embolism of the Central Retinal Artery occurred without evidence of cardiac disease. About three weeks ago there was sudden failure of the left eye, with the appearance of a thick film before it. The vision had somewhat recovered in part of the field since. She was suffering from amenorrhœa at the time. Although there was not much change in the size of the arteries there was the typical cherry-red spot at the macula. Although at first he regarded it as a case of embolism, he had since thought that it might have been a hæmorrhage into the optic nerve sheath which had affected the vascular supply of the nerve.—Mr. HARTRIDGE spoke of a recent case of embolism of the central artery in a healthy man. When the patient was seen two hours and a half after the occurrence there was already œdema of the retina.—Mr. BICKERTON mentioned a case he had seen lately in which there was very little apparent change in the vessels, and the pupil acted to light.—Dr. BATTEN cited a case of sudden failure of sight in an anæmic girl, with very slight changes in the vessels.—Mr. DRAKE-BROCKMAN said that some time ago he had seen a woman who, with a sudden attack of giddiness, had completely lost the sight of one eye. The patient was anæmic, but was free from cardiac disease or albuminuria.

Mr. HOLMES SPICER showed a case of Retro-bulbar Optic Neuritis occurring in a healthy man sixty-eight years old

Digitized by Google

whose sight had been failing for seven months. He had been a great smoker, but had given up smoking. There was no history of rheumatism, gout, or syphilis, no locomotor ataxy or disseminated sclerosis, and no renal disease or diabetes. The optic discs were very pale and slightly swollen. The fields were quite full, but he had a large colour scotoma at the fixation point. The case presented all the features of a severe tobacco amblyopia, but recovery had not followed abstention from the poison; he had got steadily worse.—Mr. GRIFFITH thought that the pallor of the discs in the case exhibited was too intense for uncomplicated tobacco amblyopia.—Mr. JOHNSON TAYLOR considered the case was an aggravated one of tobacco neuritis complicated with alcoholism.—Dr. HABERSHON suggested that the case occupied an intermediate place between tobacco amblyopia and the family cases of optic atrophy described by Leber.—The PRESIDENT said that cases were sometimes met with in which tobacco produced much graver changes in the nerve than were usually met with, and these were generally those of old men. The present case he considered might be of that class.

Dr. ORMEROD and Mr. HOLMES SPICER showed a case of Recurrent Paralysis of the Third Nerve with Migraine. A boy aged fifteen had had complete paralysis of the left third nerve when a year old; recovery took place. When he was about seven years old he had a second attack; since then he had had an attack every nine or ten months. He was subject to "bilious" attacks, with intense headache on the left side, and the paralysis always came on during a bad attack. There was some atrophy of the left optic nerve, and some of the paralysed muscles had never recovered. The present attack was passing off, but there were still slight ptosis, a dilated pupil, and complete paralysis of the external muscles of the eye supplied by the third nerve.

Mr. WAREN TAY showed a case of Recent Double Ptosis with Loss of Convergence and Weakness of the Internal Recti. There was no apparent cause for the attack; at first the movements of the eye were good, but complaint was made of diplopia; later the failure of convergence was marked. Recovery quickly followed the use of iron and nux vomica.

Mr. TREACHER COLLINS showed a case of Paralysis of both Internal Recti. A man aged twenty-two had suddenly had paralysis of both internal recti five days ago, accompanied by headache. He was unable to move either eye towards the nose either in looking to one side or in convergence. The pupils acted normally and vision was good; his gait was unsteady, his knee-jerks were exaggerated, and he became unsteady on standing with his eyes closed.—Dr. TURNER made some remarks on the probable seat of the lesion in the last two cases.

The following case and card specimens were shown:

Mr. DONALD GUNN: Peripapillary Atrophy of the Choroid of Unusual Character.

Mr. SPENCER WATSON: Specimen of an Eye lost after Removal of a Foreign Body by the Electro-magnet.

Mr. JESSOP: Specimen of Papilloma of the Conjunctiva.

HUNTERIAN SOCIETY.

Exhibition of Specimens.

AN ordinary (pathological) meeting of this society was held on Dec. 11th, the President, Mr. C. J. SYMONDS, being in the chair.

Dr. F. J. SMITH showed two specimens of Tubercle of the Choroid taken from a case of tuberculous meningitis.

Mr. COTMAN showed a specimen of Perforating Ulcer of the Stomach taken from a man forty-eight years of age.—The PRESIDENT spoke on some points in the diagnosis of the occurrence of perforation, and quoted some cases of correct and incorrect diagnosis within his own experience.—Dr. F. J. SMITH also spoke of the difficulties of diagnosis and advised operation (even exploratory) when perforation was diagnosed.—Mr. OPENSHAW said there was no difficulty in posterior perforations.—Mr. COTMAN replied.

Dr. J. H. SEQUEIRA showed a specimen of Rheumatoid Arthritis taken from a dissecting-room subject. The left shoulder-joint was affected, and there was atrophy of the biceps muscle.—Mr. CAMPBELL MCDONNELL discussed the relationship of rheumatism and rheumatoid arthritis, as did also Dr. GLOVER LYON, and Dr. SEQUEIRA replied.

Mr. OPENSHAW showed: (1) a Solid and Sarcomatous Growth of the Ovary weighing 7 lb. 7 oz.; (2) a Sarcoma of the Kidney removed by operation from a man twenty-four years of age, which had only been growing five months and weighed several pounds; and (3) a Myeloid Sarcoma of the Middle of the Shaft of the Femur, for which he had performed amputation at the hip-joint by a method of his own.—In connexion with Mr. Openshaw's second case, the PRESIDENT mentioned a large abdominal tumour which had existed for more than six years without apparent increase or much serious discomfort to the patient; he thought it was an adenoma of the suprarenal capsule, but had not been able to obtain a necropsy when the patient died from an intercurrent disease.

SOUTH-WEST LONDON MEDICAL SOCIETY.

Hydro-nephrosis.—Lightning Stroke.—Septic Pneumonia.—The Treatment of Incised Wounds.—Exhibition of Cases.

A CLINICAL meeting of this society was held on Dec 11th, Dr. GILBERT RICHARDSON in the chair.

Mr. THOS. S. HOWELL read notes of an interesting case of Hydro-nephrosis in which the obstruction in the ureter was believed to have originated in a strain at the age of thirteen years; the patient died suddenly from hæmorrhage into the sac at the age of forty-four years.

Mr. PERCY POPE read notes of the following cases: (1) Five Cases of Lightning Stroke occurring Simultaneously; and (2) a Large Quantity of Morphia taken Subcutaneously with Suicidal Intent.

Mr. M. G. BIGGS read notes of a case of Septic Pneumonia.

Mr. A. E. DODSON made some remarks on the Treatment of Incised Wounds, advocating the avoidance of the use of water in surgical incisions.

Mr. JOHN GAY showed a patient who had received a Gunshot Wound above the Right Elbow, causing extensive Laceration of the Tissues and Severance of the Musculo-spiral Nerve. The healing of the wound was followed by complete loss of power in the forearm, which was entirely restored by a ten months' course of massage.

Dr. A. D. ROE showed a case of Mitral Disease in a boy.

Dr. M. MACKINTOSH showed a case of Empyema in a boy which had been entirely cured by one aspiration.

ÆSCULAPIAN SOCIETY OF LONDON.

Exhibition of Case and Specimen.—Diphtheria successfully treated with Antitoxin.—Intestinal Obstruction.

A MEETING of this society was held on Dec. 6th, Dr. E. F. WILLOUGHBY, President, being in the chair.

Mr. W. C. WORLEY showed a case of Extensive Molluscum Fibrosum in a man of poor mental and bodily development aged fifty-two. The growths, which varied from the size of a pea to that of a small grape, had appeared gradually during the past six years, were numerous, and were distributed over the body above the knee, but especially on the face and neck.

Mr. W. C. M'DONNELL read notes of a case of Diphtheria successfully treated with Antitoxin. The usual clinical signs of diphtheria were present, breathing became stertorous on the third day of treatment, and the urine, examined on the fourth day, contained a trace of albumin. Antitoxin was injected (15 c.c.) on the third day, and again (10 c.c.) on the fourth. Within two days of its use all the symptoms had greatly improved, and recovery was uninterrupted. Löffler's bacillus was not isolated in a specimen of mucus first examined, but it was found in a second.

Mr. A. QUARRY SILCOCK read notes of two cases of Intestinal Obstruction. In Case 1 the patient was seen in consultation with Mr. Beaman Hicks. The obstruction was evidently low down in the large intestine. An exploratory median incision showed the colon to be much distended. It was, therefore, punctured and the puncture closed with Lembert's sutures. A malignant tumour could then be felt in the sigmoid flexure. The colon was stitched to the abdominal wound and opened thirty-six hours later. Recovery was rapid. The patient in Case 2 was seen in consultation with Mr. Hoskins. The same symptoms were present and the same operative procedure was adopted as in Case 1. The colon could not, however, be brought up to the mesial incision, and a left inguinal colotomy was therefore performed. Recovery was rapid, but the patient died some

Digitized by Google

months later. Mr. Silcock emphasised the utility of the exploratory method pursued in these cases as being efficient and as obviating injury by bruising, &c., to the distended structures.

Mr. G. STEVENS showed a specimen of Rupture of the Heart. The patient, a man aged seventy-six, became collapsed after the passage of a stool and died within three-quarters of an hour. It was found that the left ventricle was ruptured by a small aperture posteriorly, near the interventricular septum. The loss of blood had evidently been gradual. The heart tissue was fatty, and showed also the microscopic signs of pigmentary infiltration.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.
(METROPOLITAN BRANCH.)

Outbreak of Enteric Fever.

A MEETING of this society was held on Dec. 10th, Dr. YARROW being in the chair.

Dr. SIDNEY DAVIES read a report on an Outbreak of Enteric Fever distinctly traceable to a particular milk-supply, though the actual cause could not be discovered. Plumstead had been comparatively free from the disease, the number of cases notified in the past three years having been 22, 29, and 26, and up to the beginning of May of the present year there had been 6 scattered cases as regards time and place. Between the 9th and 11th of that month 6 cases, all getting their milk from this dairy, had been reported, but he did not apply for a closing order until the number had risen to 25 by the 15th. The milk was nevertheless sold surreptitiously, and on the 29th there had been 92 cases. In the following weeks 47, 21, 7, and 6 and between June 26th and 30th 4 fresh cases were reported, besides 13 in July. Of the 177 cases occurring in the district up to the nd of June 159, or about 90 per cent., were proved to have had their milk directly or indirectly from this dairy—33 of them from a shop in Woolwich which was supplied from the Plumstead dairy. How many cases may have occurred in Woolwich from the same milk could not be ascertained, and the epidemic must have continued to rage there had the dairyman been content to obey the letter of Section 71 of the Public Health (London) Act, selling his milk exclusively in Woolwich, but the notoriety he obtained by defying and evading the magistrate's order, for which he was again summoned and fined, led to the breaking up of his establishment and the sale of his stock on May 28th. The occurrence within a few weeks, at a time of year at which enteric fever does not usually prevail, of six or seven times as many cases as had previously been known to arise in a whole year, pointed to some extraordinary cause; and the fact that 90 per cent. of these were proved to have had milk from a single dairy left no room for doubt as to its influence, which was confirmed by the decline of the epidemic following the cessation of the sale of milk after the interval required for incubation; but had the business not been conducted so irregularly as it was, without books, &c., an even larger percentage of the cases might have been traced to the same source. In 44 of 141 houses regularly supplied by the dairyman's carts there were 65 cases. Of 49 houses in certain streets supplied by him 29 were invaded, but only 2 of the remaining 150. The 177 cases included 74 males and 103 females; 23 were under five years of age, 41 from five to ten, 57 from ten to twenty, 45 from twenty to forty, and 6 over forty, one of these, a mild case, being seventy-one years of age. Besides these there were several suspicious cases of diarrhœa among infants. The cases sent to hospital numbered 113, with 13 deaths, and those treated at home 64, with 10 deaths, or 11 and 15 per cent., in marked contrast to the usual mortality of scarlet fever &c., and probably due to the more careful dieting of patients in hospitals. The case mortality in Plumstead had previously been 22 per cent.; possibly the lower rate on the present occasion might have been owing to the larger proportion of children attacked in a milk epidemic. An inspection of the dairy showed the drains to be everywhere unsound, the yard gulleys defective, the rain water pipes connected with the drains, and the cowsheds extremely dirty. The water-supply was that of the Kent Company, and as drawn from the taps was of its well-known purity, but there was a brick tank, lined with cement, from which the water was baled for the cows, and possibly for washing the cans. The tank was green and the water turbid, the former evidently not having been cleaned for months or years; and the milk was kept in a cellar under the house, where it was possibly exposed to sewer air. The cows were apparently in good health, and an examination of the milk and of the water in the tank failed to show the presence of the typhoid fever bacillus, though the bacteria in each were identical. Little value, however, could be attached to such purely negative results in the face of the overwhelming evidence of the connexion of the epidemic with the supply of milk.

LIVERPOOL MEDICAL INSTITUTION.

Endo-laryngeal Removal of "Singer's" Nodule.—A Responsibility to the Lying-in Patient from a Sanitary Point of View.—Spinal Localisation.

A MEETING of this society was held on Dec. 12th, the President, Mr. CHAUNCY PUZEY, being in the chair.

Mr. BARK showed two patients after Endo-laryngeal Removal of "Singer's" Nodule. They were both professional voice users. The first patient had completely lost his singing voice; the growth had been removed in 1892 by another surgeon, but recurred in about a year. In July, 1893, the growth was completely removed by Grant's guarded laryngeal forceps. Two weeks later he fulfilled a professional engagement and said that his voice had never been better; there had been no recurrence since. The second patient had suffered from hoarseness and loss of singing voice for over two years; the growth in this case also was removed by Grant's forceps; this was in June, 1894, and the voice had been good ever since.—Mr. BARK also showed a Papilloma removed from the Anterior Commissure of the Larynx by Gibb's snare and a patient suffering from Trachoma of the Larynx.

Dr. STEEVES read a note entitled "A Responsibility to the Lying-in Patient from a Sanitary Point of View." He thought that a variety of puerperal fever existed the result of defective sanitation, and instanced cases where he believed puerperal septicæmia was caused by atmospheric infection by sewer air. He referred to the great benefit that a puerperal fever patient derived from removal to healthy surroundings. In the city of Liverpool one-third of the puerperal fever cases reported were from houses described as insanitary. The prevalence of this disease was no necessary index of the amount of zymotic disease existing. The medical attendant when engaged for a confinement rarely inquired into the sanitary condition of the house, but Dr. Steeves thought that if the physician was not experienced in sanitary details he should not hesitate to obtain a skilled opinion. If the owner of the property refused to abate a nuisance the aid of the sanitary authority should be invoked. A protracted period of ill-health frequently followed confinement, the victim really suffering from chronic sewer air poisoning; this could only be put an end to by change of residence or an alteration in the sanitary arrangements of the house. Dr. Steeves then moved the following resolution, which was seconded by Dr. Imlach: "That, in the opinion of the members of the Liverpool Medical Institution, it is the duty of every medical practitioner, when engaged to attend a confinement, to forthwith inspect, or cause to be inspected, the premises of the patient, with a view of having any sanitary defects which may exist corrected, and so further the stamping out of puerperal septicæmia by the methods of preventive medicine." Several members spoke on the resolution, some stating that, in their opinion, insanitary conditions had nothing whatever to do with puerperal septicæmia; others thought that the resolution to be effectual should apply to every kind of illness, and not specially to the puerperal woman. It seemed to be generally agreed that it would be very unwise that any such resolution should go forth to the public from the institution, and on being put to the vote it was rejected by an overwhelming majority.

Professor SHERRINGTON drew attention to the Localisation of Function in the Spinal Cord as illustrated by the distribution to the skin of the sensory spinal nerve pairs arising from the cord. He pointed out that experiments show the field of skin supplied by each sensory spinal nerve root to be a large area of somewhat simple configuration. Where simplest—that is, in the trunk and neck—the segmental skin field is band-like, wrapping transversely round one lateral

Digitized by Google

half of the body. In the limbs the spinal skin fields are distorted and are disconnected from attachment to the median line of the body, whereas in the trunk and neck each of the spinal skin fields extends from the mid-dorsal line to the mid-ventral line. In the region of the limbs the mid-dorsal line of the body may be said to extend laterally in a side branch, forming a secondary axis almost at right angles to the main axis; upon this secondary axis, which may be called the limb axis, the spinal skin fields are ranged as though upon folded portions of the axial lines of the trunk itself. Each spinal skin field spreads out to a marked extent into neighbouring spinal skin fields, and in this way has an overlap into the field in front and the field behind. There is, therefore, no area of skin which is supplied by one spinal nerve alone; the supply is from two roots in some places, as in the palm, and in others from three roots. Although in a plexus each sensory spinal root gives separate contributions to many nerve trunks, the cutaneous distribution of the root composes a field, not of discrete or disjoined patches, but of patches so joined that the distribution of the entire root forms one continuous field. Numerous slides were shown in the lantern of the various skin fields as met with in the monkey.

Professor PATERSON described the Distribution of Spinal Nerves to the Skin and Muscles of the Trunk and Limbs of Man. By means of a large parti-coloured model he showed how closely the skin fields in man correspond with those found experimentally by Professor Sherrington in the monkey. He pointed out that, while superficially segmental in origin, the spinal nerves are truly segmental in distribution only to the muscles of the thoracic wall—where the segmental elements forming muscles have combined, the segmental nerves combine also, forming plexuses. With regard to cutaneous innervation it was certain that overlapping takes place in the distribution of the simplest type of nerve, so that it was possible to affirm that no spot of skin and no muscle (except the inter-costal muscles) are supplied by a single spinal nerve. With this qualification the cutaneous innervation of the trunk between the limbs is zonular—continuous belts of skin are supplied from back to front by the branches of the third to the twelfth thoracic nerves. The growth of the head and limbs causes the adjacent nerves to be drawn out of their primitive position. In the limbs, lines (dorsal and ventral axial lines of Sherrington) could be drawn from the middle line of the body down the limbs and indicated the meeting-place of widely separated nerves; it is only at the ends of these lines that a continuity of distribution appears. It is seen in the limbs that, in spite of the apparent complexity due to the combination of the spinal nerves in the plexuses and in the nerves of distribution, a definite arrangement exists by which the skin and muscles are supplied by a gradually descending series of spinal nerves, proceeding from the pre-axial to the post-axial borders of the limbs.

MANCHESTER MEDICAL SOCIETY.

Chorditis Tuberosa.—Pathogenesis of Cancer.—Malignant Endocarditis.—Tuberculous Disease of the Mucous Membrane of the Middle Ear.

A MEETING of this society was held on Dec. 4th, the President, Mr. F. A. SOUTHAM, being in the chair.

Dr. YONGE showed a case of "Singer's" Nodes of the Vocal Cords in a boy aged fourteen, without history, and without symptoms except partial loss of the upper register in singing. The unusual features of the case were the absence of hoarseness or symptoms of laryngeal fatigue (which are met with in the majority of such cases), the peculiar position of the nodes, which were situated about the centre of the cords instead of anterior to that point, and the absence of any history of laryngeal overstrain. The cords, in spite of being "weighted," as it were, by the nodes, vibrated in a similar manner to healthy cords. This was proved by blowing indigo on to the cords, when the particles moved outwards in a curved line towards the ventricles during phonation, behaving in precisely the same manner in which, as Dr. Hodgkinson has shown, they do in the normal vibrating cord; the efficient vibration explained the absence of vocal impairment in the case.

Mr. ROGER WILLIAMS, in his remarks on the Pathogenesis of Cancer, said that for many years the microbic theory of cancer had been so much the order of the day that no other had been able to obtain a hearing. Inasmuch, however, as the cancer microbe had not yet been discovered, and as collateral indications of its existence were conspicuous only by their absence, he thought the time had now come for setting forth a rival theory, and that was the task to which he proposed to address himself. It was evident that out of the confusion of a transition period but two conceptions as to the origin of neoplasms had emerged, the one based on the cell theory and the other on the microbe theory, and henceforth the struggle must be between these two. The question now was, Did cancers and other neoplasms arise, as J. Müller maintained, through a modification of the formative process, or were they the outcome of the inflammatory process owing to the presence of microbes or other sources of irritation *ab extra?* In other words, Were neoplasms essentially of *intrinsic* or *extrinsic* origin? He inclined to the former alternative and thought that the future would see a decided reaction in this direction. Having entered at some length into the various considerations favourable to this view, the conclusion was reached that in the great majority of cases the outbreak of cancer was entirely spontaneous and could not be attributed to the immediate action of any appreciable extrinsic cause whatever. In the genesis of neoplasms, as in the genesis of other organic structures, two factors must be taken into consideration—the *cells* whence they originate and the *force* that regulates the cellular activities. Lowly organised cells abounded in all parts growing and capable of growth, and these were the only real cancer and tumour germs. The essence of the neoplastic process was that certain cells of the affected part grew and multiplied more rapidly than their congeners, regardless of the requirements of the adjacent tissues and of the organism as a whole. The essential feature of malignancy was the persistency of this undue proliferative activity. The process by which cancers and other neoplasms arose might be regarded as a kind of abnormal generation, the tumour being the result of this modified super-induced repetition of the developmental process, and its qualities the result of the degree of emancipation of its constituent cells. Hence the genesis of cancer and other neoplasms was a phenomenon of the same order as discontinuous growth in general.

Dr. DRESCHFELD gave a communication on the etiology of Malignant Endocarditis. Of the organisms found some did not occur in other affections; others were well-known microbes, such as the staphylococci, streptococci, and pneumonococci. In some rare cases the typhoid bacillus, the bacillus of tuberculosis, the bacillus of diphtheria, and the gonococcus had been found. Of the predisposing causes besides pyæmic and septicæmic diseases, the acute zymotic diseases, pneumonia, and chronic endocarditis, Dr. Dreschfeld mentioned chorea, which in one case, without any previous endocarditis, was associated with malignant endocarditis, and related a case where rupture of one of the aortic valves from overstrain was soon followed by malignant endocarditis. The season had also some influence on the occurrence of malignant endocarditis; several of the cases observed commenced during the months of September and October. Of the various clinical forms, one was specially referred to where the chief symptom, besides the physical signs of endocarditis, was an intermittent pyrexia, the temperature rising only a few degrees for several hours, and being soon succeeded by a normal temperature. The rise of temperature was ushered in by a sensation of cold or distinct chill and general malaise; during the afebrile period the patient feels comparatively well. These cases often go on for months. They usually terminate fatally; occasionally, however, they recover. The examination of the blood during life, withdrawn by means of a syringe from a vein, gave often negative results on microscopic examination and on cultivation; occasionally, however, an organism (usually a streptococcus with virulent properties) was obtained. Large doses of quinine and the administration of arsenic appeared to give the best results. Several cases with typical signs of malignant endocarditis (intermittent or remittent pyrexia, symptoms of embolism, &c.) recovered under this treatment.

Dr. MILLIGAN read a paper upon Tuberculous Disease of the Mucous Membrane of the Middle Ear. In the first place he pointed out the insidious onset of the affection. The occurrence of a discharge from the mucous membrane of the middle ear, unaccompanied by pain or any of the usual symptoms of an acute sthenic inflammation, and the presence of a perforation in the centre of a pale, œdematous, and uninflamed membrana tympani, should always excite suspicion. The presence of enlarged cervical glands and the early appearance of facial paralysis are also important symptoms.

Digitized by Google

Special reference was made to the occurrence of facial paralysis in these cases, and its comparative rarity in non-tuberculous middle-ear affections. In order to definitely establish the tuberculous nature of such cases scrapings of portions of diseased bone, removed from the interior of the mastoid process, were taken and inoculated subcutaneously into guinea-pigs. In the course of from two to five weeks the animals were killed, and scrapings from enlarged glands taken and examined for bacilli. Microscopic sections of the liver and spleen were also made and examined. Of ten cases thus experimentally examined eight proved to be tuberculous and two non-tuberculous. Great stress was laid upon ascertaining the essential character of the morbid affection, not only from the point of view of treatment, but also from that of prognosis. In tuberculous middle-ear affections the prognosis is grave, and the younger the patient the graver the prognosis, thus differing very materially from simple inflammatory non-tuberculous cases, where the prognosis is good. Free removal of all diseased foci of bone should be undertaken, and, in general, to effect this it will be found necessary to open the mastoid cells. Good food, tonics, and fresh air are all essentials in the treatment of such cases. The paper was illustrated by lantern slides, microscopic sections, and dissections of guinea-pigs.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens. — The Symptoms and Diagnosis of Malignant Diseases of the Larynx. — The Retinacula of Weitbrecht or Cervical Ligaments of Stanley.

A MEETING of this society was held on Dec. 11th, Mr. A. W. PRICHARD being in the chair.

Dr. EDGEWORTH showed a patient with Unilateral Neuritis of the External Popliteal Nerve.

Dr. PROWSE showed specimens from a case of Acute Nephritis in which the inferior vena cava was plugged with clot, leaving a small central channel; both pulmonary arteries were plugged with similar clots.

Dr. SKERRITT showed a specimen of Diffuse Cancer of the Stomach.

Dr. MICHELL CLARKE showed a specimen of Aneurysm of the Ascending Aorta communicating with the Superior Vena Cava, and Dr. SHINGLETON SMITH and Professor FAWCETT spoke on the subject.

Dr. WATSON WILLIAMS read a paper on the Symptoms and Diagnosis of Malignant Diseases of the Larynx, illustrated by patients and drawings.

Professor FAWCETT read a paper, illustrated with numerous specimens and diagrams, on the Retinacula of Weitbrecht or Cervical Ligaments of Stanley.—Mr. HARSANT and Dr. EDGEWORTH commented on the paper.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Radical Cure of Hernia.

A MEETING of this society was held on Dec. 5th, the President, Dr. PORTER, being in the chair.

Mr. SNELL showed: (1) A large number of Stereoscopes with Photographs illustrating Eye Operations and methods of examining eye patients; (2) an Electrolysis Needle, and introduced a woman with embolism of the central artery of the retina.

Mr. RICHARD FAVELL showed Gynæcological Specimens and gave particulars of a successful case of Nephrectomy.

Dr. SINCLAIR WHITE exhibited and made remarks on: 1. A Successful Case of Laminectomy for Complete Paraplegia due to spinal caries. The paralysis had been present for upwards of a year and had resisted seven months' treatment by continuous extension and other recognised expectant plans. The patient, a boy eight years of age, was operated on five months ago and could now walk well. The arches of the fourth, fifth, and sixth dorsal vertebræ were removed and a large cavity corresponding in extent to the body of the fifth dorsal vertebra cleared out. 2. Upwards of 300 Gall-stones removed from a woman. Dr. White, instead of stitching the cut edges of the gall-bladder to the wound in the parietes, tied them over a glass tube with a constriction at the point of ligature. This plan had answered well by saving time at the operation and by keeping the wound free from bile during its healing. 3. A Child with Supernumerary and Webbed Fingers and Toes.

Mr. CLYDE L. HAYES showed a case of Malignant Disease of the Tongue.

Dr. CUFF showed: (1) A woman with a large Venous Nævus of the Tongue; and (2) a boy aged ten with Enchondromata on the Left Hand.

Dr. ARTHUR HALL showed cases of Melanoderma and Syphiloderma.

Dr. GWYNNE read a paper on the Radical Cure of Hernia. He maintained that it was one of the most successful operations of modern surgery, relieving the patient not alone from grave inconvenience but also from the ever-present danger of strangulation. He advocated Macewen's method of stitching up the inguinal opening, but thought that ligature and excision of the sac simplified the operation and produced as good results, especially in children, as Macewen's mode of dealing with it. In Dr. Gwynne's opinion this applied with still greater force to congenital herniæ. In cases of the latter he preferred closing the ring with stout ligatures so as to restore the valvular condition of the canal, and subsequently ligaturing the sac as high up as possible without excising any portion, due care being taken not to include or otherwise injure the spermatic cord. A number of cases were exhibited dating from one to five years after operation.—The PRESIDENT, Dr. SINCLAIR WHITE, Dr. WILKINSON, Dr. GWYNNE, Dr. BURGESS, Dr. SWEETEN, and Dr. ADDISON discussed the cases and paper.

PLYMOUTH MEDICAL SOCIETY.

General Paralysis of the Insane.

AT a meeting of this society on Nov. 30th, Mr. SQUARE in the chair, a paper was read by Mr. A. N. DAVIS, the medical superintendent of the Borough Asylum, on General Paralysis of the Insane. After dealing with the symptoms, causation, and course of the disease, Mr. Davis pointed out the frequency with which this disease occurs amongst the annual admissions to the asylum, overcrowding, heredity, alcohol, and syphilis being the principal causes. No case had been reported as recovered, but remissions were relatively frequent, and these principally amongst the maniacal types. The melancholic cases were chiefly females, amongst whom no remission occurred, but on the contrary their disease rapidly progressed to a fatal termination within twelve months from admission. The cases of longest duration were not marked by any continuous mental excitement or severe convulsive seizures, but gradually drifted into steadily progressive dementia. Expansive delusions and pupillary anomalies characterised all the male cases, but beyond a feeling of passive contentment no such delusions were the rule amongst the female paralytics.—In the discussion which followed Dr. ALDRIDGE (Plympton House Asylum) remarked on the large amount of trouble which cases of general paralysis caused to asylum superintendents owing to the fragility of the bones in the second and third stages and alluded to the large proportion of general paralytics coming under Dr. Davis's care. He himself had only had seventeen cases in twenty-four years, or 8 per cent. of the admissions, male and female. The cases usually became rapidly fatal after admission into an asylum—in the third stage in about six months. He mentioned syncope as an occasional cause of death; he had never seen a female general paralytic, though such cases were not uncommon in the upper classes at the present day. He had seen no case absolutely cured. The prognosis was not difficult; when asylum treatment commenced a man's affairs should be put in order.—Mr. BULTEEL asked as to the part played by injury as a cause of general paralysis.—Mr. RIDER cited two fatal cases due to worry in temperate men of the Royal Navy.—Dr. PEARSE had only seen one genuine case. — Dr. MARIETTE also inquired as to injury in its causal relationship.—Mr. WHITEFORD asked whether influenza was a common cause.—Mr. SQUARE objected to the name as a misnomer for a collection of symptoms which indicated brain disease.—In reply Mr. DAVIS said two female cases—both in prostitutes—were rapidly fatal; he also cited a case where a second remission of symptoms had taken place. He said several cases now in the borough asylum were put down to influenza.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens.—"Brief Sketches from my Breviary" &c.

A MEETING of this section was held on Nov. 22nd, Dr. LOMBE ATTHILL, President, in the chair.

Dr. W. J. SMYLY showed three specimens of Ectopic Gestation, all of which had been removed by operation, the patients making good recoveries. Double Pyosalpinx (two specimens): both recovered. Uterus removed in a similar case: abdominal section; attempt to remove tubes failed after rupture of one with extravasation of pus; vaginal hysterectomy; abdominal cavity shut off with Mikulicz's bag; recovery. Pedunculated Myoma larger than adult fist: the soft tumour was diagnosed as dermoid of left ovary, but was found to be a myoma; recovery. Myomatous Uteri (four specimens): hysterectomy in all cases; one death. Cancerous Tumour of Left Ovary: operation simple; sudden and severe internal hæmorrhage the same evening; abdomen reopened, bleeding controlled, and abdomen cleared of clots; convalescence uneventful until ninth day; complete paraplegia with anæsthesia, loss of reflexes in lower limbs, and paralysis of bladder; some fever for a week, then normal temperature, but paralysis persists.

Dr. E. WINIFRED DICKSON exhibited a Fibro-myoma removed from the Cervix Uteri. The patient was aged thirty years and had borne four children. The last pregnancy had ended a few weeks previously, at six and a half months; there had been severe hæmorrhage on this occasion, and the tumour had been then diagnosed. The symptoms had been slight, consisting only of a dragging sensation in the pelvis, dating for a year back, and some glairy discharge. The tumour was attached by a short broad pedicle to the front and left side of the cervical canal from the os externum nearly to the os internum. The posterior lip was hypertrophied, and the glands much enlarged. The tumour was removed with scissors, and the edges of the wound united with sutures. There was not much hæmorrhage. The patient made an uninterrupted recovery.—Dr. SMYLY remembered only two specimens of myoma of the cervix which had been shown to the Academy. One of these was shown by himself.—Dr. ALFRED SMITH remembered one which Dr. Macan had exhibited, and in which there were adhesions between it and the vagina.

Dr. ALFRED SMITH showed a Uterus with large Fibro-cystic Tumour which was removed by complete hysterectomy. The tumour extended one finger's breadth above the umbilicus, was very elastic, and growing rapidly. Palpation showed that the tumour had a long pedicle, and several small daughter cysts were growing from the fundus of the tumour. Vaginal examination: The uterus was separated from the tumour by a broad pedicle; its fundus was well studded with small fibromata, and was greatly enlarged. The diagnosis of ovarian tumour was made. Abdominal section revealed a fibro-cystic pedunculated tumour growing from the left side of the uterus, and the fundus of the uterus invested with small fibroids. The entire removal of the tumour and uterus was determined upon.

Mr. R. A. FLYNN exhibited a Uterus removed by Vaginal Hysterectomy for Cancer. He said:—"A woman aged forty-six had ten children, and at the birth of the last, four and a half years ago, I attended the patient. She consulted me in January last for backache and pain in the left side. On vaginal examination I found the os uteri turned towards the anterior vaginal wall, the cervix lacerated, and through the posterior vaginal wall I found the corpus uteri lying backwards on bimanual examination. There was retroversion of the uterus, which was quite movable; the adnexæ were normal; the sound passed two and a half inches, causing neither hæmorrhage nor pain; the point passed backwards. The speculum showed nothing abnormal. The uterus was easily replaced bimanually, and a No. 8 Smith's pessary was introduced. I saw the patient a week afterwards and found the uterus in good position and her symptoms relieved. I did not see the patient again until Nov. 3rd, when she consulted me for menorrhagia which had lasted two months. On vaginal examination I found the cervix enlarged, with its tissues so friable that it could easily be broken down with the finger, causing considerable hæmorrhage. On bimanual examination I found the uterus normal in size and position, and the adnexæ normal; the speculum showed a large ulcerated cervix. I removed the pessary and the uterus went very quickly into the position of retroversion. I now removed a piece of the cervix with a knife for microscopic examination, and sent the tissue removed to the Clinical Research Association, London, and received the following report on Nov. 9th:—'The specimen removed from the cervix uteri shows an early infiltration of the tissues with a squamous-celled epithelioma.' Dr. Smyly kindly saw the patient with me on Nov. 11th, and agreed with me that it was a favourable case for vaginal hysterectomy. The operation was performed on Nov. 14th, the broad ligament being secured with Landon's clamp forceps; the clamps were removed in forty-eight hours. The patient has up to the present (Nov. 22nd)—nine days after the operation—made an uninterrupted recovery. The case I regard with hopefulness, as I was fortunate in getting her at an early stage, and consider that there is a good chance of the non-recurrence of the growth."

Mr. WALTER BERNARD read a paper entitled "Brief Sketches copied from my Breviary, of the priceless sayings of other men, with some remarks showing what valuable outposts they were in helping me to extend the boundaries of my knowledge, and to avert death while practising the obstetric art." He said:—"While engaged in general practice many as well as myself cannot but feel how essential it is for the common good, as well as for an example to those who follow, that some proof at certain stages of our careers ought to be given that we are keeping our lamps well oiled and trimmed during the well-timed changes in preventive medicine. From my breviary I shall awaken some of the lore of the past and present. From the time of Hippocrates down to our own times puerperal fever, its lore and complications, were mystified and vague, and not until 1860 was the disease clearly defined. Strother, in 1718, was the first to give it the name of puerperal fever. Smellie, a great compiler of the thoughts of other men, then came to the front, making known his mistakes and failures, and being no "secret monger" he did not fossilise his experience. Since Smellie's time much has been written on puerperal fever, but it was not until the great discussion on it, held in London in 1875, that its accurate relations to infective diseases were made apparent. Eclampsia, taken by itself, is rare. A few cases follow one another, not often seen by a medical man until soon after a seizure. During utero-gestations there are occasionally marked signs of a coming storm which will be found in books, and which by proper treatment can be frequently averted. The headache, giddiness, failure of sight, and œdema of limbs sound a warning note. As to treatment, one of the old rules holds good: if plethoric, bleed; if anæmic, do not. Administer chloroform, hydrate of chloral, enemas, purgation, and the hot-air bath. For the induction of premature labour no absolute rules can be enforced, but in this state of things a level-headed consultation is absolutely necessary. Some of the prodromata of the so-called functional and organic hemiplegia are curiously alike, such as the numbness, giddiness, tingling, dragging, and cardiac and vascular changes. Some of these had a gouty or syphilitic history, and early arterial degenerative changes appeared in some before middle life. A few had a history of chorea in childhood. My records show that too much dependence was placed on the local treatment of dysmenorrhœa and too little on the general management of patients as regards condition and family history. In placenta prævia the well-known and carefully thought-out rules ought to be followed. Ancient forceps, like crania, are of much interest, as they exhibit the intelligence of men coequal with their cranial formations. Laceration from the driving power of ergot and the untimely and unskilled use of the forceps is almost a thing of the past. Their skilful management, together with that of the perineum, need not be gone into. So far back was external pressure used in retained placenta that it was unknown in remote antiquity when it commenced. Patience in the vanished past, as well as in Guillemans's time in 1609, was recommended. It was not even known when the 'Dublin method' commenced, which Credé of Leipzig brought under the notice of the German School in 1860, modifying it according to his views. At one time pressing off the placenta had its advocates. The practice did not last long when it again came into fashion some years ago. Post-partum hæmorrhage is not common now, as medical men and nurses are better trained, and the causes are more fully investigated. But yet occasional

Digitized by Google

cases are met with, and consequently every medical man's ether and uterine syringes ought to be always antiseptically ready and in good working order. And send at once for the nearest help, throwing reputation, money, and mutual distrust aside while life is swinging in the balance. Let us do our duty at any cost, even at the risk of our own lives; but to save lives outside we ourselves must work, and if we work honestly we can be independent and rise above the level of all that is acrid, trivial, and temporary."—Dr. MACAN said they had listened with great pleasure to Mr. Bernard's paper, which had touched on almost every subject of midwifery. They felt very much indebted to him for coming from Londonderry to read it.

SECTION OF PATHOLOGY.

Tumours of the Kidney composed of Suprarenal Tissue.

A meeting of this section was held on Nov. 29th, Dr. CONOLLY NORMAN, President, being in the chair.

Dr. MCWEENEY described two new cases of Tumours of the Kidney composed of Suprarenal Tissue and discussed the subject, which has hitherto escaped notice from English-speaking pathologists. His first case was that of a left kidney successfully removed by Mr. Coppinger at the Mater Misericordiæ Hospital in March, 1892, from a woman aged fifty-three, who is still alive and well. The lower part of the kidney is converted into a large cyst, from which a bowlful of brain-like hæmorrhagic material was evacuated during the operation. The walls of the cyst are ragged and covered with adherent masses of tumour tissue. The second case was that of a woman aged thirty-eight from whom a huge mass of confluent tumour nodules occupying the position of the left kidney was removed by Mr. Lentaigne at the Mater Misericordiæ Hospital last September. The only recognisable part of the kidney left was its upper extremity. The nodules were not unlike liver in appearance and consistency; many were as large as the closed fist; all were distinctly encapsuled, and none showed signs of advanced degenerative change. Microscopically these two tumours agreed in their close resemblance to the suprarenal cortex. They consisted of large polygonal or cubical epithelial cells, with a small, round, centrally placed nucleus, arranged without intercellular substance in elongated rows or circular groups separated by blood capillaries. The tumour cells were placed directly on the capillary wall, which simply consisted of a line of endothelial nuclei. In the first tumour the deposition of fat and glycogen was a marked feature. There was but little fat and no glycogen in the second. This would appear to show that the deposition of glycogen is not, as Lubarsch supposes, an essential feature of tumours of this kind, but is merely associated with retrogressive change. The origin of certain tumours of the kidney from suprarenal "rests" was first pointed out by Grawitz in 1883. His results were extended and generalised by Horn. Dr. McWeeney came to the same conclusion as Lubarsch—viz., that they must really be considered as derived from dislocated suprarenal elements. Thirty-two such cases are now on record, many of which took a malignant course and formed metastatic deposits in various organs. Nephrectomy had proved a very fatal procedure even in the absence of peritonitis and uræmia. In one of the cases now brought forward two pounds of morphologically perfect suprarenal cortex, free from degenerative change, were present in the body, a fact not without significance in view of the high physiological activity now known to be possessed by this tissue.—Dr. O'SULLIVAN said that when in Vienna last summer he had seen two of these growths. The first was like Dr. McWeeney's first case. It was an encapsuled mass confined to the upper part of the kidney, and consisted of pultaceous material infiltrated with blood. There was no metastasis. No microscopic examination was made. The other was of more pathological importance, since in the kidney itself there were several masses of the same character, but also a considerable amount of metastasis in the bones.—The PRESIDENT said the Academy should be congratulated on having received such a learned paper from Dr. McWeeney. There was a case published in the *Journal of Pathology*, about three years ago, by Dr. Kanthack and Dr. Rolleston resembling in many ways that of Dr. McWeeney. Another case, not mentioned by Dr. McWeeney, was published in France in 1882 of adenomata of the kidney.—Dr. MCWEENEY, replying, said that he had not as yet been able to look up thoroughly the English literature on the subject. He had, however, consulted Dr. Rolleston's Lectures on the Suprarenal Capsule, which were most exhaustive. In the class of cases Dr. McWeeney was referring to, the tumour originated in the kidney, altogether apart from the suprarenal. In both of his cases the tumour originated in the lower end of the kidney. The fully formed tissue of these tumours is not like urinary tubules. In the cortex of the human suprarenal, but more especially in that of the higher mammals, pseudo-tubular structures of the same kind were found by Creighton, Marchand, Pfaundler, and others.

Reviews and Notices of Books.

Archæological Survey of India: The Bower Manuscript. Facsimile Leaves, Nagari Transcript, Romanised Transliteration and English Translation, with Notes. Edited by A. F. RUDOLPH HOERNLE, Ph.D., Principal, Calcutta Madrasah. Part II., Fasciculus II. Published by Order of the Government of India and under the Patronage of the Bengal Government. Calcutta. 1895.

[SECOND NOTICE.]

WE took the opportunity of giving some account of this very interesting archæological publication in October last year,[1] after the appearance of the first portions of the work, and referred more especially to the main portion of the manuscript containing a treatise on Medicine. The second fasciculus of the second part of the publication is now before us, completing the medical portion, or rather as much of it as was saved from destruction. There are fourteen chapters on thirty-one leaves; that portion which contained the fifteenth and sixteenth chapters is lost. The size of separate leaves is about 11½ in. by 2½ in. The writing, in Nagari character, is in black ink, mostly on both sides of the leaves.

"The whole manuscript when discovered consisted of fifty-six leaves[2] of birch bark, some in single thickness and others from two to four thicknesses. Some of the leaves appear perfectly fresh and clear, others are much discoloured. All are very brittle and tender. The leaves are enclosed between two boards, and a string runs through them." The *whole* MS. consists of five distinct parts, and is written almost entirely in *slokas* or verses: firstly, the medical portion now consists of thirty-one leaves; the second part contains a collection of proverbial sayings, on five leaves; the third part has a story of how a charm of snakebite was given by Buddha to his disciple Ananda whilst staying in the Garden of Anathapinda, on four leaves; fourthly, another collection of proverbial sayings, on six leaves; and, fifthly, a fragment of another medical work, on five leaves. Besides these there are a few detached leaves unconnected with one another and with those of the larger portions.[3]

Professor Hoernle, with rare erudition and perseverance, was able to interpret the meaning of the whole MS., which he transcribed in the original Nagari with a transliteration into Romanised characters, and translated the medical portion of it into English, which is now completed. Professor Hoernle adds very copious notes and references, comparing them with other Hindu medical treatises, from which it appears that the prescriptions of the author occur almost word for word in the works of Charaka, Susruta, and Vangasena, the old Hindu medical and surgical authors.

Our interest very naturally centres around the now completed medical portion of the MS., the "Navanîtaka," or "The Cream," as its author calls it. In our first notice we have mentioned the division of this treatise into sixteen chapters, and have culled from it a curious prescription, containing thirty-six ingredients, for a powder which is to

cure almost every conceivable disease the flesh is heir to, and if taken for two months without interruption it will secure the patient's life for one hundred autumns. The author, whoever he may have been, was a Buddhist by religion and wrote in Sanskrit, although not in the most classical style of that language; the copying of the MS. was done by several scribes, portions of it being written in a careless and slovenly manner.

Beyond its antiquity, as the most ancient medical manuscript known to exist in the Sanskrit language, dating from about the fifth century of our era, this work possesses no special value for medicine of the present day. Verses 43, 45, and 50, however, contain the following sensible doctrine:[4] "The normal condition of elements, health, energy, and long life are all dependent on the digestive faculty ..... through all these, life of living beings is prolonged. Hence one should first of all examine the state of the digestive faculty ..... a wise physician will at all times, in all diseases, first direct his treatment to the proper regulation of the digestive faculty." This very much coincides with the advice given by an eminent physician recently deceased to a well-known patient. There are prescriptions for treating cases of cholera, diphtheria, stone in the bladder, &c.

We feel we ought not to conclude our notice of this manuscript without giving an account of its discovery by that indefatigable traveller, Captain Bower, and the romantic circumstances connected with it. Captain Bower says: "While at Kuchar, in Kashgar, Eastern Turkestan, a man offered to show me a subterranean town, provided I would go there in the middle of the night, as he was frightened of getting into trouble with the Chinese if it was known that he had taken a European there. I readily agreed, and we started off about midnight. ..... The subterranean ruins of Mingai, to which my guide had promised to take me, are situated about sixteen miles from Kuchar, on the banks of the Shahyar river, and are said to be the remains of Afrasiab's capital. ..... The same man procured me the packet of old manuscripts. They had been dug out of the foot of one of the curious old erections (Buddhist *stupas*) about fifty to sixty feet high, broad in proportion, and resembling somewhat a huge cottage loaf, of which several are to be found in the Kuchar district."[5] This is the find to which Professor Hoernle gave the appellation of "Bower Manuscript" in honour of its discoverer.

On Brain and Nerve Exhaustion (Neurasthenia) and on the Nervous Sequelæ of Influenza. By THOMAS STRETCH DOWSE, M.D., F.R.C.P. Edin., &c. London: Baillière, Tindall, and Cox. 1894. Price 2*s.* 6*d.*

AT the last meeting of the British Medical Association but one the discussion on Neurasthenia and its Treatment was introduced by Dr. Savage in the following words: "What is neurasthenia? There was once a professor who, being asked what he knew upon a certain subject, replied, 'Nothing; I have not even lectured on it.' This is rather how I feel in relationship to the subject on which I am to open a discussion. We have a disorder whose very name is not without difficulty, for the classical scholar only recognises it as neurasthĕnīa, while we medical men are content to call it neurasthēnīa."

In face of so frank a confession by an acknowledged expert it was with no great expectation of enlightenment that we took up Dr. Dowse's *brochure*, albeit a carefully revised fourth edition. Before embarking upon a systematic perusal of the work we commenced our task by glancing rapidly through the pages, which are admirably printed. Almost at once our attention was arrested by the subjoined passage: "Occasionally a spark of science scintillates in the ever-increasing and heterogeneous detritus which man is vain and pleased and conceited enough to call knowledge. This scintillation is wisdom. The cosmology of nature, the evolution, devolution, and involution of conceptual properties, based upon analytical and synthetical deduction, constitutes an appreciative something which we call 'facts in nature.' The revelation through the agency of perception and reflection by coördination and correlation develops faculty; and when such is the outcome of an initial and intuitive potentiality the giant genius springs into existence and illumines by intensity and expansive radiation."

After this we felt that if it were a fair sample of the remainder we had, indeed, embarked upon an arduous voyage. On the very next page we found it stated that, "in dealing with human life and thought, we have in the plainest possible language to deal with human individualities." There seemed to be promise of better things here, and we consequently felt emboldened to persevere. Soon another paragraph stood out, as it were, from the luxuriant context: "Conceit and ignorance are usually twins by birth; and even by culture they are both propagated by the same soil and nourished by the same elements; they are both intolerant, selfish, cruel, and utterly devoid of reciprocity, sympathy, or charity." Then came: "As a physician I should indeed be a dreaming dotard if I failed to comprehend, to realise, to estimate, and to value the significance and the importance to mankind of our constant and progressive accumulation of knowledge. ..... No one doubts the enormous power and self-sufficiency of knowledge"—*id est*, of the "heterogeneous detritus," &c., of a page or two before! The following passage is even still more remarkable: "Does the cultivation of science, upon its purest scientific lines, ennoble the nobility of human nature, or has it not a tendency to elaborate certain faculties at the expense of others, and thus lead to prejudice, bigotry, jealousy, and conceit? Power, and especially self-acquired power—for power born is vastly different to power bred—has through all ages been attended with vainglory and a supreme admiration for self. Has science altered this? No. It cometh like the wind and goeth like the wind. It seems as though it were the final links in the great and continuous chain of evolutionary conditions." In the face of such high-strung eloquence it may perhaps appear a trivial interruption to inquire where the final links in a continuous chain are situated?

Having managed to read the eight introductory pages of the book, we became aware of some alarming symptoms not unconnected with exhaustion, and had it not been for Dr. Savage's encouraging opinion that neurasthenia is seldom caused by brain fatigue we should incontinently have given in. Fortified by this authoritative dictum, we ventured once more on our course. Soon we reached a paragraph which, although inordinately long, it is really quite impossible to leave unquoted. Here it is: "The greatest learning, sagacity, and knowledge have been expended to unravel, evolve, interpret, and arrange the connexions which link and bind together the physiological, anatomical, and pathological signs and symptoms which are developed, extracted, and produced by some unknown factor directed in the evolution and dissolution of that strange, wonderful, related, but to us exceptional, region which forms an oasis between the physical, the material, the moral, the intellectual, the mental, the ideational, the metaphysical, and the psychical, and which, when viewed from the hopeless belief of the physicist, the materialist, and the scientist, forms a realm entirely subordinate to the great evolutionary doctrine, which at one time was looked upon as the revolutionary, transmitting, and metagenetic power which should bring light out of darkness

[4] Ibid., p. 181.
[5] Proceedings of the Asiatic Society of Bengal, p. 221, 1890.

Digitized by Google

and convert an unknown problem of infinite omniscience to the level of the sagacity, the intelligence, and the understanding of the mind of man. When we look around and note the feeble, weak, illogical, impotent stuff ....." The passage does not really end here, but space is too important to be recklessly filled.

Proceeding on our weary quest we next arrived at eight "propositions ..... of interest." The first two are appended: 'That in neurasthenia there exists a want of correlative integrity between the cerebro-spinal and sympathetic centres, and, in my opinion, this is the fundamental cause, and is often but not necessarily hereditary. That there is defective antagonism between the centres at the various levels, cerebral and bulbo-spinal, by which a process or processes of inhibition are started and maintained. Governing and controlling centres are subjugated by restraint, so that controlling power is greatly diminished."

Peradventure the reader will understand what is meant by "correlative integrity" and "defective antagonism" in this connexion? A little further on the symptoms of neurasthenia are stated in great detail under a dozen heads. No one with the smallest tendency towards hypochondriasis should read this portion of the book unless he wants to be frightened out of his wits. The succeeding thirty pages or so, treating as they do *de omnibus rebus et quibusdam aliis*, must be left unsurveyed.

Concerning treatment we find "each case must be studied closely and carefully by itself. I must say that this has been my own experience." Dr. Dowse does not believe in iron and quinine or in electricity for neurasthenia. Opium "continued for some weeks, and it may be months," is his dangerous sheet anchor, in spite of the admission that "it may be necessary to increase the dose." He also recommends full doses of hydrate of chloral, and this notwithstanding his own warning with reference to alcohol: "It must be remembered that we are dealing with a class of people whose resisting power is of the lowest order—who are liable at any moment to give way to any idea which is uppermost in their vacillating minds and to gratify every passion."

Some very elementary matter is next inserted with regard to heat-producing and flesh-forming compounds; and interspersed there are many remarks about foods, children, dyspepsia, gout, koumiss, Board schools, and dipsomania, which for want of space and other reasons cannot be further alluded to. The neurasthenic dietary formulated by the author must not, however, be dismissed in any such summary manner. His "general advice" to his patients on the subject is as follows: "Don't rise until eight o'clock in the morning. ... ... Take breakfast with fish or a well-cooked chop or rump-steak. ... ... At eleven o'clock take a glass of dry sherry and a biscuit, or a new-laid egg beaten up with port wine. ... For luncheon, at half-past one, take oysters.....(or) a basin of really good soup, which should be followed by a cut of mutton or beef from the joint.....You may drink a wine-glass of whisky, with a bottle of Apollinaris. At 4 o'clock a small cup of immediate tea may be taken with some dry biscuits—avoid the sweet, tempting cakes which are now so freely supplied with this meal.....The dinner should never consist of more than four courses—namely, soup, fish, joint, and game. Never mix your wines, but vary them every three or four days, sometimes taking a dry champagne, at other times a good well-seasoned, sound burgundy." That's all. There is absolutely nothing ordered for supper.

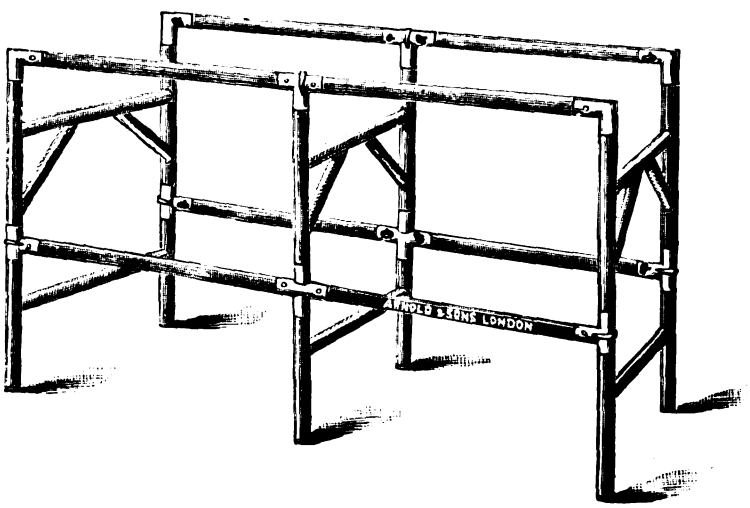
Transactions of the West London Medico-Chirurgical Society. Vol. VI. London: Baillière, Tindall, and Cox. 1895. Price 5*s*.

THIS volume is edited by Mr. J. H. Menzies and Dr. Clemow, and shows unmistakable signs of the flourishing condition of the society. Abstracts of very many interesting papers are given as well as a full report of the two Cavendish Lectures, one by Mr. Henry Morris on Some Changes in Surgical Opinion regarding the Diseases of the Urinary Organs, and the other, by Sir William Broadbent, on Some Points in the Treatment of Typhoid Fever. The reports of the clinical evenings are highly instructive and give the accounts of a large number of very good cases which were shown, and altogether this volume is well got up and presented in a readable form.

The Practice of Massage: its Physiological Effects and Therapeutic Uses. By A. SYMONS ECCLES, M.B. London: Macmillan and Co. 1895. pp. 375. Price 7*s*. 6*d*.

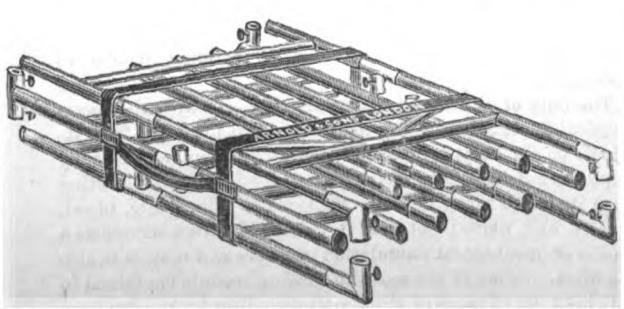
IN spite of writings neither obscure nor few, it may be safely asserted that a really scientific exposition of the much-abused subject of massage has hitherto not been available in English medical literature. To a great extent this gap has been filled by the monograph before us, which deserves to be widely read and studied, for its chief merit lies in the exposition it gives of the physiological basis of this therapeutic measure and the appropriate application of it to the relief of many a chronic malady. Nor is it possible to peruse its pages without being convinced that the art of the masseur is one not easily acquired, and demanding of its practitioner a more than superficial knowledge of bodily structure and function. It is, moreover, clear that it is not possible, even with such detailed descriptions as are here given of the methods of "effleurage," "pétrissage," "tapotement," "vibration," and "massage à friction" to convey to the learner the more or less delicate differences of manipulation that can only be imparted by practical demonstration, whilst it is also obvious that the practice, to be thorough and effective, demands no little dexterity and endurance. From all which it follows that there must be much so-called "massage" which is far from attaining the height of excellence to which the author points, whilst from the therapeutical standpoint the method is likely to suffer from mal-application in some cases and unsuitable employment in others. Dr. Symons Eccles writes with a confidence born of experience, and on p. 263 he deplores the "apathy which still pervades the medical world in this country" as to the proper supervision of massage; and doubtless he has reason for this remark, for any therapeutic measure is liable to fall into discredit if it be wrongly applied or ignorantly perverted from its main object. In the same connexion he goes on to say that "it is unfortunate, both for practitioners and the public, that no measures have yet been taken to provide for the efficient teaching and practice of massage and medical gymnastics in the great schools of medicine attached to our hospitals, in which thousand of cases must exist in want of such treatment by more careful and thorough massage than can be obtained under present conditions." These remarks are made in regard to the treatment of chorea, a malady in which regulated muscular exercise is *primâ facie* a rational course to encourage.

The bulk of the work is naturally occupied with the therapeutical application of the method. That massage, from its effects on the circulation, promotes metabolism, and thereby improves nutrition, explains in general terms the good resulting from its use in many chronic affections of skin, joints, blood, muscle, and nerve; but that it is also of direct service as a means of mechanical stimulation of nerve and muscle is also manifest. Some of the most interesting records contained in this book are of cases of chronic gastric disorder and habitual constipation—conditions which prolonged drug treatment often tends to aggravate rather than to relieve—where no doubt can remain of the efficacy of massage treatment. Equally instructive are the descriptions of various forms



Digitized by Google

of nervous disease, organic as well as functional, which are amenable to the same therapeutic measure. Indeed, it is in the neuroses especially that massage has had some of its most striking successes, but Dr. Eccles is emphatic in the opinion that for its proper guidance and conduct it is essential that the medical man himself should be fully cognisant of its powers and their limitations. If by this work he succeeds in gaining for the practice more serious attention in this country at the hands of those who prescribe it, he will have done not a little to redeem the practice from the subsidiary position that it mostly occupies. Whilst making every allowance for mistaken conclusions, there remains a sufficient body of evidence to prove that the method of massage, properly and scientifically applied, is physiologically correct, and therefore rational and appropriate in the treatment of diseases.



New Inventions.

A PORTABLE BAMBOO OPERATING-TABLE.

THE surgeon upon arriving at a private house where preparations have been made for an operation usually finds a kitchen table or perhaps even a dining-room table of, say, three flaps, enough to seat sixteen guests comfortably, got

ready to support a patient weighing perhaps 8 st. If the assistant had merely to look at the proceedings with a spy-glass across the vast superfluous expanse of table there would still be grave inconvenience caused by the little space left for instrument tables, &c. I generally ask permission to

obtain from the upper storeys two plain deal dressing tables. These, though often rickety, serve, when divested of their pink calico hangings, to support the weight of the heaviest man, fairly distributed as it is over the eight legs of the two tables; and I am certain that, at least for private use, a far lighter operating-table would suffice than any hitherto described.

Messrs. Arnold and Sons, London, have made for me one with a frame of stout bamboo with aluminium furling rod-joints fixed by thumb-screws. The top is of stout waterproofed canvas, descending eight inches down the sides and ends and removable. The whole table can be washed with soap, soda, and warm water just as easily as the waterproof sheeting between the carbolised towels and the patient, and is just as aseptic. The table can be tilted to an angle and kept so by placing the legs of one end on a box. The weight without the cover is 25½ lb.

C. B. KEETLEY, F.R.C.S. ENG.,
Surgeon to the West London Hospital.

THE "EXCELSIOR" BED SUPPORT.

THIS bed support was first brought into use at the Birmingham General Hospital during the present year, it being designed to prevent patients from slipping down in bed. It consists of a strip of woven wire mattress webbing two feet long and five inches wide, covered with a cushion and fixed in a sloping position on vertical brackets attached to a horizontal board. Straps or bands of stout ordinary webbing fastened to the ends of this board and buckled to the head of the bedstead keep the support in any desired position on the mattress. When the patient is in the recumbent attitude with his knees flexed and the back of his thighs resting against the cushion of the support, he is securely maintained in a comfortable position free from any tendency to slip towards the foot of the bed, for the pressure of his weight is resisted by the straps buckled to the head of the bed. The appliance, in fact, imparts to an ordinary mattress some of the convenience of a reclining chair in which there is a hollow to receive the lower part of the back. The manufacturers are The Bed Support Company, The Butts, Coventry.

ICKRINGILL'S PATENT HYGIENIC AND ELASTIC CLOTH.

THE special characteristic of this cloth depends on the circumstance that its thickness and softness—equal to those of stout flannel—are produced by a peculiar arrangement of the fibre, which is brought out endways on one of the sides of the fabric, giving a surface somewhat like thick short fur. The longitudinal threads of the cloth, being of caoutchouc render it very elastic, while it is pleasantly smooth, soft, and velvety to the touch and thoroughly pervious to air and moisture. A notable advantage of this material is that it may be washed with soap and hot water without its elastic properties being impaired and without the troublesome tendency, as in flannel, to become felted. Abdominal belts are manufactured of the cloth, a purpose for which it seems to be very well suited, as it not only affords the necessary mechanical support, but fits smoothly in consequence of its elasticity, secures protection and warmth, and does not confine the moisture of the skin. The cloth is made of varied strength, and one of the thinner qualities is made up into roller bandages of the ordinary form. The manufacturers are Ickringill's Patent Hygienic and Elastic Cloth Syndicate, Limited, 35, Devonshire-street, Keighley, Yorkshire. Messrs. Maw, Son, and Thompson, Aldersgate-street, are the London agents.

WEST-END HOSPITAL FOR NERVOUS DISEASES, WELBECK-STREET, W.—Sir W. H. Broadbent has accepted the post of consulting physician on the staff of this hospital, rendered vacant by the death of Dr. Bristowe. Owing to the resignation of Dr. Hughes Bennett on account of ill-health Dr. T. Outterson Wood becomes the senior physician, Dr. W. Wallis Ord is promoted to second, and, by arrangement with Dr. de Watteville, the beds allotted to the third physician to in-patients have been taken over by Dr. Fletcher Beach.

THE LANCET.

LONDON: SATURDAY, DECEMBER 21, 1895.

THE paper of Dr. NEWSHOLME on a National System of Notification and Registration of Sickness communicated to a meeting of the Royal Statistical Society, and reported in abstract in another part of our present issue, will be read by all who feel interested in the national health. The audience to which Dr. NEWSHOLME mainly addressed himself was the Statistical Society, and through it the public. His views met with more criticism than concurrence, but all admitted the interest of the paper as a whole, and all would be ready to admit that the system of registration which he advocates is the logical completion of the system of death registration. This system originated in this country, and has been copied by our neighbours of the Continent. Dr. NEWSHOLME would persuade us to follow their example in the registration of sickness. It is impossible to deny that the registration of mere mortality affords very inadequate information. Many grave diseases causing extensive suffering and temporary disability for the duties of life do not cause death. It is very gratifying to know that, however backward we are in this country in the registration of sickness, we have long had men amongst us who were alive to its importance and who have more or less carried it out on a limited scale and in a voluntary way, either alone or in combination with those whom they were able to entice into coöperation. Amongst them Dr. NEWSHOLME made honourable mention of Dr. (now Sir) B. W. RICHARDSON, Dr. RUMSEY, Dr. ARTHUR RANSOME, and others.

In 1869 Mr. GOSCHEN was approached as President of the Poor-law Board by a deputation headed by Dr. RICHARDSON, urging legislation to procure the registration of sickness. Mr. GOSCHEN expressed hearty approval of the suggestion, but pointed out—and for this the profession cannot be too grateful to him—that care should be taken not to impose additional labour on the Poor-law officers. It would even seem that in the beginning and middle of last century there were men who advocated the registration of disease. But with all this historical advantage and impetus we are behind other nations—Belgium, Germany, Denmark, Sweden, and Norway. It is true that lately in the Factory and Workshops Acts sections are found requiring notification of cases of poisoning from lead, arsenic, phosphorus, or anthrax to the Chief Inspector of Factories at the Home Office, also to the inspector and to the certifying surgeon for the district. But there is no attempt in these Acts to require a return of general sickness, or even of any of the more common diseases which in some of the countries specified by Dr. NEWSHOLME are reported. In some of the countries named by Dr. NEWSHOLME a large number of constitutional diseases are required to be reported; also a large number of local diseases. The hospital statistics of the German towns include every individual infectious disease, and others also, to the number of 144. Syphilis and gonorrhœa, phthisis, pneumonia and pleurisy, chronic alcoholism, acute rheumatism, and other rheumatic affections are among the diseases included in the hospital statistics. Dr. NEWSHOLME seems to think it would be possible and proper for the State to require similar returns from its own hospitals and from hospitals supported by charity. Lord THRING and others failed to see by what right the State could demand returns from private hospitals sustained by charitable voluntary subscriptions. The fact is that in this country the people have two marked characteristics which ardent sanitarians are prone to forget—they are jealous of any unnecessary encroachment on their personal liberty and privacy, and they do not like too much refinement in legislation. They would not tolerate the method described in an interesting speech by Dr. WEEKS of Portland, Maine, U.S.A., as the legal one in his State—the placarding in scarlet of the dwelling in which there is a case of scarlet fever or diphtheria or small-pox. This would seem a cruelly excessive publication of the domestic affairs of a British citizen. And if they submit to registration or notification of disease it is not that they like it, or for its own sake. As Lord THRING said, they only submit to it for the ulterior purpose of isolation. If notification is to have no consequence or efficiency, it will be sure to be resented and removed. This brings us to the real test of such measures as the registration of sickness proposed by Dr. NEWSHOLME, and to a perception of the force of the strong current of criticism with which they were received. He was careful to say in his reply that it was far from his intention to recommend a general registration of sickness. In the paper he argued that everything but "age" itself came within the care and the concern of preventive medicine; and so it does—but such excessive care is apt to be resented by ordinary people, and by the ordinary member of Parliament, who is bound to respect their views. If there were any strong case made out for returns of any given disease this reluctance would give way, especially if it were shown that such returns would lead to any practical remedies that legislation could promote. And this is practically all that Dr. NEWSHOLME wants. At any rate, it is all that he is likely at present to get. He would do well to define a few—a very few—diseases of the constitutional class on which information is most wanted, and to begin any system of registration of sickness with them. Public opinion would sanction some extension of the notification principle in regard to other infectious diseases than those now notifiable. They are clearly a class by themselves. They endow the patients suffering from them with a power of affecting and injuring others, which gives these others an interest in, and even a right to interfere with, their personal liberty. But the case of incommunicable diseases is very different. It may be so extensive and so injurious, and withal so amenable to legislative measures, as to justify State notice. But all this has yet to be made clearer before it can be embodied in practical legislation.

Dr. NEWSHOLME realises that when a wider notification is called for it will necessitate a revision of the notification fees. It should be clearly understood that medical men

Digitized by Google

are to be recompensed for the imposition of such additional work, either by direct payment or, as he suggests, by additional legal guarantees for the protection of the profession from vexatious prosecutions.

THE subject that has been under discussion at the last two meetings of the Royal Medical and Chirurgical Society is one which has often exercised the minds of thoughtful clinical observers, and one, too, in which renewed interest has been taken since the tacit assumption that infective diseases are due to the invasion of the body by specific parasitic organisms. The phenomena of the diseases in question are in the main explicable on the theory of the implantation of germs which undergo continuous development in the blood and tissues, inducing the morbid changes peculiar to the special disease of which they are the cause. The stages of incubation, of active manifestation, local and general, and of decline and recovery concord precisely with the development, activity, and ultimate fate of the micro-parasites in their struggle with the cell forces of their host. It is also quite in agreement with what is known concerning the life-history of allied non-pathogenic organisms, that under appropriate environment and in suitable soil the development of the pathogenic parasite is favoured and encouraged. Similarly the facts of immunity are capable of satisfactory explanation from analogies derived from our knowledge of the conditions of life in the vegetable world, as in the exhaustion of the soil, although it may well be that other conditions are operative in the case of the animal organism for which no counterpart can be found in the macrocosm. At any rate, the present position of pathological interpretation in this matter is this general admission of the fact of pathogenic germs as the essential factor in diseases belonging to the so-called infective groups. The discovery of the actual microbes in certain of these diseases, and the exhaustive studies that have been made of their morphology and development in artificial media, have not only added to the clearer comprehension of their *rôle* in disease, but have amply sanctioned the inference of the existence of like agencies in allied affections.

If, then, what is known of the ordinary clinical history of infective disease harmonises with observed facts of the life-history of specific bacterial organisms, it becomes a matter of importance to determine whether variations in the course of the former are concomitant with, or, rather, consistent with, variations in the conditions of the latter. Perhaps the most remarkable of such departures from the ordinary evolution of a disease is the reappearance, after a long interval, of the manifestations peculiar to it, a recrudescence of symptoms which can only admit of one of two explanations—either that it is due to fresh infection or that it means a reawakening to vitality of germs long since implanted in the body, which for some reason or other have fallen into a state of quiescence or dormancy. This is the question which has been so ably debated at the Royal Medical and Chirurgical Society, the general outcome of which debate has undoubtedly been to strengthen the belief in the latency of disease germs, and this from direct bacteriological evidence as well as from clinical and pathological observations in the human subject. As Mr. HUTCHINSON, in his admirably suggestive remarks at the opening of the debate, observed, a distinction must be made between true latency and a latency which is only simulated. In the first the assumption is that the disease germs are actually in a state of quiescence, as dormant in the tissues of the body as the grains of wheat in the Egyptian sarcophagus, awaiting only some special condition to restore them to vitality; in the other instance, they may be supposed to be silently exerting their influence, but without any overt manifestations of their presence. The adoption of a belief in true latency, which, as Dr. WASHBOURN showed, is consistent with bacteriological knowledge, would certainly afford an explanation of facts in the history of syphilis, tuberculosis, and leprosy which were so well advanced by Mr. ERNEST LANE, Dr. KINGSTON FOWLER, and Dr. ABRAHAM. The view, however, is capable of very wide application, as Mr. HUTCHINSON indicated in reference to vaccinal erysipelas, and Sir W. BROADBENT in respect to typhoid fever. It may also be applied to the explanation of direct inheritance, not only in syphilis, but in regard to tuberculosis, thus reinstating a doctrine somewhat shaken of late years by a too rigid belief in the contagiousness of tubercle.

One aspect of this doctrine as an alternative to that of reinfection from without is deserving of careful analysis. It was referred to by several speakers, and has been often discussed elsewhere. This is the determination of the conditions that are requisite for calling into activity the dormant microbes. More than one speaker alluded to the influence of traumatism as an apparent exciter of latent infectivity. In some cases this is fairly obvious, but in others it is very mysterious and inexplicable. Why should injury of a joint evoke tuberculosis in it? or why should a slight blow be followed by tuberculous meningitis? Inexplicable as this agency is, it is not more so than the admitted agency of chill, which is the direct antecedent of many diseases that are admittedly microbic in origin. We explain this by stating that chill lowers the vital resistance of the organism; but why should it equally stimulate the latent germs to activity? There is, indeed, ample scope, not only for speculation, but for arduous research in the endeavour to harmonise the facts of specific infection with those of apparent spontaneous outbreak of disease. As regards the fact of latency of germs we think there can be no dispute. It is impossible, for instance, to explain the sudden outburst of tuberculous meningitis in a subject who has caseous foci in glands or elsewhere on the theory of reinfection. Long before the bacillus tuberculosis was discovered such outbursts of acute tuberculous infection in those who had such foci in the body were recognised, and were regarded as the chief danger from which it was almost impossible to protect the subject. The cases cited by Dr. FOWLER in respect to pulmonary tuberculosis hardly admit of any other explanation. As to syphilis, the doctrine of latency has long been held, and is, indeed, often the only explanation available to explain the life-long liability to further infection that is associated with

Digitized by Google

this disease. If, then, the teachings derived from analogy, the experiences of the bacteriological laboratory, and the observed facts of clinical experience, all point to the fact of latency of the germs of disease, the concordance of testimony is too great to be disregarded.

A SPECIAL meeting of the governors of the Chelsea Hospital for Women was held on Wednesday afternoon, Lord GLENESK presiding. The purpose of the meeting was to consider the propriety of the governors dispensing with the services of a member of the honorary medical staff. Under all ordinary circumstances such a proceeding should have been possible to the governors in a manner that would call for no controversy. But the Chelsea Hospital for Women is a luckless institution; for, although the result of the meeting of the governors was to cordially endorse the action of their executive body in the expulsion of the medical officer in question—in which action they were supported, it should be added, by the whole of the medical staff, the impeached officer excepted—yet the outcome of the meeting cannot be considered satisfactory. There are many points remaining which suggest debate of an acrimonious character, and which may possibly receive that unfortunate attention. Therefore we say that the Chelsea Hospital for Women is a luckless institution, for its executive are unable to take a strong and decided action. A trail of ills follows their various departures, and the name of the hospital becomes associated in the public mind with what, for lack of a more dignified word, we must term "rows."

Briefly, the case is as follows, but an account of the meeting is given in another column. Mr. O'CALLAGHAN made changes in the organisation of the hospital. Whether these changes were or were not reforms is no question before us now, but it is our most strongly held opinion that to place any nurse, however capable, in a position of superiority to the resident medical officer of the hospital, will always be in direct contradistinction to the manner in which hospitals should be conducted, and such a course, if uniformly adopted, would end in the ruin of all proper medical administration. Having instituted this "reform" (for Mr. O'CALLAGHAN'S action certainly did place the resident medical officer in a subordinate position to a nurse), a dispute arose between Mr. O'CALLAGHAN and the resident medical officer as to the after-treatment of one of his operation cases. Out of this dispute there arose a dispute between Mr. O'CALLAGHAN and certain members of the staff as to the said operation. The propriety of the operation was unquestioned, and the manner of its execution was not impeached. The dispute was simply whetner what had been done was of the nature that had been suggested in consultation. Mr. O'CALLAGHAN says that it was and Mr. BLAND SUTTON says that it was not. The dispute has obviously arisen out of a sad error, but either side may be right without affecting the merits of the case, for though Mr. O'CALLAGHAN'S colleagues, holding him as the mistaken person, find him impossible to work with, the lay executive of the hospital have clearly stated that they were not acting in response to the wishes of their honorary medical staff in desiring from Mr. O'CALLAGHAN his resignation, but entirely upon their own responsibility. Following on these unfortunate occurrences the board, as we have indicated, called upon Mr. O'CALLAGHAN to resign. He refused. They offered a form of arbitration. For this reason and that reason the proposal came to naught. Finally, on Wednesday afternoon, the board made a motion for Mr. O'CALLAGHAN'S expulsion, which, being endorsed by a general meeting of governors, was carried by 106 to 17.

What was the real point at issue? Not Mr. O'CALLAGHAN'S opinions of the duties of a house-surgeon. Not Mr. O'CALLAGHAN'S accuracy, which has been gravely impugned. The question before the meeting was, Is such a "row" a domestic one, or is it one upon which arbitration from outside should be invited, the executive of the hospital being unable to manage the affairs of the hospital properly? Mr. O'CALLAGHAN was making no categorical defence; he was simply asking for arbitration. We have no hesitation in saying that under ordinary circumstances arbitration would have been unnecessary. Under ordinary circumstances a board of governors would have been the proper people to deal with the situation. But the management of the Chelsea Hospital for Women is not governed by a properly constituted lay board. They are under a stigma. They should never have undertaken the business of the election of their present medical staff. At the time they did so they lay under the censure of an independent tribunal. We refer to the committee of investigation appointed by the hospital authorities to inquire into Dr. PARKES'S statements that he considered that the lay management of the hospital was unsatisfactory. As a result of that report the medical staff of the hospital resigned, and the lay management should have done the same. They were equally to blame then, and they still rest under the shadow of that blame. Now Mr. O'CALLAGHAN has been dismissed by this discredited lay board. A strong board above criticism, backed by its medical officers, should be able to discharge not one, but fifty honorary medical officers. But the lay management of the Chelsea Hospital for Women is not strong, and in undertaking the dismissal of Mr. O'CALLAGHAN without formulating the charges against him, and giving proper reasons for refusing the conditional arbitration for which he prayed, they have made a mistake. On the merits of the case we express no opinion, but as to the value that arbitration would have had as a method of dealing with the case we have no doubt.

ROYAL BRITISH NURSES' ASSOCIATION.—The eighth annual conversazione of the Royal British Nurses' Association was held on Monday, Dec. 7th, in the galleries of the Royal Institute of Painters in Oil Colours, London. Princess Christian, the president of the association, was unavoidably absent, but many distinguished guests attended, among them being Lord and Lady Halsbury, Lady Dimsdale, Lady Dorothy Nevill, Sir T. and Lady Lawrence, the Rev. Sir Borradaile Savory and Lady Savory, Sir J. Crichton Browne, F.R.S., Sir J. Eric Erichsen, Sir Richard Quain, and Sir Dyce and Lady Duckworth. The guests, who numbered some 2000, were received by the vice-chairman of the executive committee, Sir J. Crichton Browne, Mr. T. Pickering Pick, and Miss Thorold, supported by the honorary officers of the association, Mr. Langton, Mr. Fardon, and Mrs. Dacre Craven.

Annotations.

"Ne quid nimis."

THE CASE OF MR. LIONEL SMITH.

WE are sure that all our readers will be glad to see from a letter which appears in another column that some slight redress has been made to Mr. Smith for all the injuries which he has suffered during the past eight years. For a full account of the case we must refer our readers to our issues of Feb. 9th and Aug. 24th; but to recapitulate shortly the facts are these. In 1887 Mr. Smith was acting medical officer at Albany. In the following year a patient in the Albany Colonial Hospital died, and a coroner's jury of three persons attaching blame to Mr. Smith on this account, the Government dismissed him, allowing an appeal to the Secretary of State, who upheld the Governor's decision. Mr. Smith then, having been refused a hearing before the Medical Department in West Australia, entered a petition of right with the Colonial Secretary as defendant. The jury, after one trial in which they disagreed, eventually found for the plaintiff with £200 damages for wrongful dismissal, but on the question of whether he had or had not been wrongfully dismissed they could not agree. In the end the Privy Council ordered judgment to be entered for the Government of Australia. This is a very short and bald statement of a grievous and cruel wrong inflicted by the Government upon an absolutely innocent man. Government took away his livelihood and his character, so that he is left, a middle-aged man with a wife and children, to begin the world over again. It will be seen from the letter in our correspondence columns that Mr. Chamberlain, true to his Bechuana name of "the one who rights things," has offered Mr. Smith the appointment of district surgeon in Zululand, a post he has determined to accept. The salary is very small, but it is something, and in order to be able to take it Mr. Smith requires funds to complete the education of his children and to provide for the passage and outfit of himself, his wife, and his family. He has been fighting his battle nobly and resolutely for eight weary years, and has now come to the end of his resources. We confidently appeal to our readers and through them to their well-to-do patients to send us such a sum as will enable Mr. Smith to face, at any rate, the immediate future without fear. Let everyone consider the woeful position of this man. Judged guilty of a crime which he never committed, maligned, deprived of all opportunities of making a living, looked upon as that much-to-be-pitied but tiresome person "a man with a grievance," with those dearer to him than his life dependent upon him, he is absolutely without means. A chance, thanks to Mr. Chamberlain, offers itself of, at all events, keeping a roof over his head and of getting food, but immediate help is wanted. Christmas is the season of all others for works of charity and mercy, and we are confident that those who have this world's goods will answer our appeal to share them with their brother who is in such sore need. Let them remember that "alms do deliver from death," rather than be placed in the category of those of whom it was said, "When they will not give a doit to relieve a lame beggar they will lay out ten to see a dead Indian." Subscriptions sent to THE LANCET office should be enclosed in an envelope marked, "Lionel Smith Fund."

LONDON WATER-SUPPLY.

THERE was no protracted debate on the question of London's water-supply at the meeting of the County Council last Tuesday. The proposal to ask Parliament to create a water trust for the control of the London water-supply was rejected, and in its stead a motion was carried by a majority of thirteen to ask the Government to place the control of the water-supply in the hands of the London consumers, who are to be directly represented by the Council in conjunction with the City Corporation. A clause is provided for consumers in the metropolitan area outside the county who "shall not be denied or deprived of similar rights in their respective areas." Further, "the purchase price of the existing water undertakings shall not be assessed under the provisions of the Lands Clauses Consolidation Act, but shall be based upon the fair and reasonable value of these undertakings, due regard being had to the rights, special circumstances, and obligations of the companies." Finally, "the Parliamentary Committee shall be instructed to report as to the reply of Her Majesty's Government immediately after the recess." The adoption of this motion will probably wrest a definite pronouncement from the Government as to the precise direction which they propose legislation should take, and their reply will therefore be one of great moment.

PLUMBER'S WORK.

IN view of the great importance in a sanitary respect of the work of plumbing we have been for a considerable time engaged in an inquiry as to the relative efficiency and cost of plumber's work. We have been much struck by the absence of any definite information as to the latter point, and have as far as possible endeavoured to supply the deficiency. Our inquiry is now practically completed, and we propose to publish in the course of a few weeks the results of our Commissioners' investigations. These investigations have been undertaken independently by us, and we are solely responsible for the result. We have thought, however, that their value would be enhanced if the report were submitted to the criticism of experts. The Worshipful Company of Plumbers very courteously and readily fell in with our views, and appointed a committee to consider our report and make suggestions or criticisms thereon. The committee have devoted much time to this work, and we shall have great pleasure in printing their report as an addendum to our own. Their criticisms, whether destructive or the reverse, will be equally welcome.

HORSELESS CARRIAGES AND SANITATION.

So novel as yet is the mere idea of street traffic without the aid of horse power that the minds of most persons can hardly have touched the practical questions involved in such an arrangement. We are not, however, wholly without evidence bearing upon this subject. The ordinary cycle, though but a toy in comparison with many larger and more complicated members of its class, and a variety of automatic wheeled machines which have appeared at times on public view, have added something to our education. The steam and electric tramcar, and even the time-honoured road engine, afford other examples of mechanical energy thus employed. We may therefore claim to know enough of the outlines of the new system of movement to sketch with an approach to accuracy some of the advantages and drawbacks which its adoption must entail. It is needless here to discuss the many economic, æsthetic, and social effects which would follow even the partial disuse of the horse as a draught animal. Another question, that of sanitation, calls for more attention from us. There can be no doubt that, as regards this important matter, the equine mechanism is somewhat lacking. Our stables without the horse would be as pure as our homes if we were ourselves visible only as figures of still life, waxen, or ivory models. The stable-pit filled with the defiled bedding of our obedient and faithful four-legged

Digitized by Google

servant would be known no more to our senses. The contagia bred in its midst and scattered in the dry dust of summer air, to find their way within our sleeping and sitting rooms, would be only the remembered signs of a past and primitive civilisation. The germs of glanders would not harbour and be hatched, as they still occasionally are, in the stalls of overcrowded mews. Thus far the margin of profit is on the side of him who charges his vehicle with steam or electric energy. Possibly he may still have grounds for anxiety, for accidents will happen, even with machinery. It is hardly to be expected, however, that this generation will witness a triumph of hygiene so marked as is suggested by the above description. The stable and the coach- or cart-house will not soon be dissociated, and the need of stringent sanitary measures on the part of their owners will remain as a pressing and continual obligation. Much remains to be done, and much can be done, in this direction in order to ensure not only the health of stabled animals, but of the human population in or near mews. The frequent and regular removal of refuse is one important means to this end, and by means of the methods, at once effectual and simple, employed for this purpose in well-kept stables the work of cleansing can be carried out with ease and completeness.

THE HOSPITAL ACCOMMODATION OF THE METROPOLITAN ASYLUMS BOARD.

WE have received, through the courtesy of Mr. T. Duncombe Mann, clerk to the Board, a copy of a letter he has addressed to the chairman, Sir E. H. Galsworthy, showing what the Board has done to meet the enormously increased demand on its space since the notification system and the wholesale admission of the public, as distinguished from paupers, to the hospitals. It makes much of what the Board has done in providing in four years five sites, on two of which hospitals have been already built. On three others the buildings have not been completed, and, indeed, on one—the Tooting permanent site—building is not yet begun. The weakest part of Mr. Mann's defence is in not showing why the Board should keep 1000 beds for a handful of small-pox cases while there is such a pressure for the admission of fever patients. We adhere to our view that the whole working of this system of huge hospitals for the admission of great numbers that presumably could be accommodated at home requires immediate and close investigation as to its efficiency and expediency. Unfortunately it is one of those questions which have no party interest, and it is too probable that we shall go on spending millions of money without curtailing the proportions of epidemics.

VITAL STATISTICS IN EGYPT.

THE Egyptians are unquestionably a very prolific people. From an official paper just published we learn that the number of native births registered during the year 1894 was 335,549, while the deaths from all causes came to 192,103 only; the excess of births over deaths amounted consequently to no fewer than 143,446, which, with an estimated population of 8,000,000, represents the enormous increment rate of 1·79 per cent. Under the existing *régime* there is no reason to doubt the accuracy of the vital returns, whatever may have been the case formerly when the military service was so unpopular that parents used every effort to prevent the inscription of their sons' names on the hated lists. Registration, thanks chiefly to the untiring labours of Dr. Engel Bey, is now very fairly carried out all over the country; and, moreover, even though a little of the old leaven should still remain, the effect of uninscribed infants would be to cause a fictitious diminution of the birth-rate. The census of 1882 is generally regarded as incorrect and misleading, because it was hurriedly taken during the height of the Arabi disturbances, but the statistics now supplied tend in some measure towards the rehabilitation of the discredited enumeration. Its details may be, and probably are, often unreliable, but the totals arrived at seem to be approximatively correct. The native population of Egypt up to the Second Cataract, and including the Oases, was put down as 6,469,716, and if we adopt that number as a basis and allow for increase from superiority of births at the 1894 rate, the calculation will be found to work out at about 8,000,000. According to this hypothesis the birth-rate last year was equal to 42 (nearly) per 1000, and the death-rate to 24 per 1000. Before leaving this portion of the subject there is one point to which we desire to draw attention as affording food for thought. In the two principal towns the difference between the birth- and death-rates is startlingly less prominent than it is in the rural districts, which are nevertheless often said to be extremely insanitary. For every 100 births in Cairo and Alexandria there were 86 deaths during the twelvemonth, whereas in the provinces the proportion was as 100 to 54. Turning to the foreign side of the tableau we find that while 2513 "strangers" died in Egypt during the year 1894, the number of births among them was only 1056. It is probable, however, that the latter total does not represent the whole of the exotic progeny, for in a note it is stated that although registration of deaths is now obligatory for all, the declaration of births is still optional for foreigners. Some years ago the idea prevailed in certain quarters that European women were nearly always barren in Egypt. There are, of course, no real grounds for the notion, but should it still be entertained we are here furnished with upwards of a thousand unmistakable proofs of its fallacy. On the other hand, it has been affirmed that the procreative powers are, if anything, enhanced by residence on the banks of the Nile, and all native Egyptians are thoroughly convinced that the muddy water of their river is in this respect infallible. In their own case there would seem to be very little doubt that, at all events, it does not act as a preventive. With regard to vaccination, it is very satisfactory to find that the operation is now efficiently performed throughout the length and breadth of the land. No fewer than 312,188 "vaccinations with success" are recorded, the number of failures being only 3548, or a little over 1 per cent. In 4045 instances revaccination was essayed, for the most part with good results, only 788 cases proving refractory at the second attempt. Since December, 1890, infants of all nationalities have been liable to compulsory vaccination.

ROYAL ACADEMY OF MEDICINE, IRELAND: THE PROPOSED NEW HOSPITAL SCHEME.

A SPECIAL meeting of the Academy was held on Tuesday last to consider the above scheme, Dr. James Little, President, being in the chair. Dr. Duffey, physician to the City of Dublin Hospital, moved a resolution to the effect that, whilst approving of the proposal to provide better accommodation for cases of small-pox and a home for patients recovering from infectious diseases, the proposed scheme for establishing new isolation hospitals for infectious cases was unnecessary and uncalled for. The proposal was seconded by Sir Christopher Nixon, who argued that the treatment of fevers in departments of general hospitals had not been attended with ill results, and he considered the proposal to establish new hospitals unnecessary and calculated to cause great expenditure of the ratepayers' money. Dr. Grimshaw, President of the Royal College of Physicians of Ireland and Registrar-General for Ireland, moved the previous question. In a very long address he pointed out the dangers resulting from treating cases of fever in other than special hospitals, and mentioned cases which had come

Digitized by Google

under his own observation in which fever had been spread in hospitals from one person to another. He considered that every case of fever was a centre of disease from which it could spread, and urged, therefore, the necessity of isolating patients completely, which could not be done in general hospitals. He had always condemned the treatment of fevers in such hospitals, and his opinion on that subject remained unchanged. Sir Charles Cameron, chief medical officer of health of Dublin, in seconding the amendment, said that if the Academy passed the resolution proposed it would be an indelible stain upon them. Everywhere except in Dublin fever was treated in special hospitals; and was Dublin right and the rest of the world wrong on that subject? The amendment was then submitted and carried by 21 to 12 votes, and as the original resolution could not then be put, the long debate anticipated did not take place. Many members left before the division was taken.

WEATHER AT MENTONE DURING TWENTY-ONE SEASONS.

WE have received from Dr. William Marriott of Mentone an analysis of the weather at that place during twenty-one years, concerning which he writes as follows:—In the choice of a winter and spring climate for an invalid, the number of fine days on which he can go out at these seasons of the year should be taken into serious account. In the following table of the weather at Mentone during twenty-one seasons, it will be seen how great is the preponderance of fine days over cloudy and rainy ones. The latter are counted rainy even if only a slight amount falls, the rest of the day being fine and allowing of walking or driving out, a continuously rainy day throughout, preventing an invalid getting out, being of rare occurrence, probably half a dozen in the season. The observations in 1886–87 were only taken up to Feb. 22nd owing to the earthquake on the following day:—

November to April.

	Fine.	Cloudy.	Rainy.
1874–75	86	59	36
1875–76	102	40	40
1876–77	104	34	43
1877–78	117	14	33
1878–79	93	19	68
1879–80	117	32	33
1880–81	104	30	46
1881–82	138	18	25
1882–83	98	30	53
1883–84	113	27	42
1884–85	119	15	47
1885–86	104	23	54
1886–87	82	4	28
1887–88	113	3	62
1888–89	120	13	48
1889–90	123	12	46
1890–91	117	21	43
1891–92	118	11	53
1892–93	122	14	44
1893–94	127	15	39
1894–95	117	15	49

Thus out of 181 days in the six months there are only from forty to fifty rainy days. Invalids can therefore look forward to 135 fine days, mostly bright and sunny, while in London during the same period they would not amount to twenty.

TREATMENT OF MALIGNANT DISEASE OF THE BREAST.

IN a paper which appears in another column, by Dr. Robert Sanderson, the question is raised as to whether it is right to stop the "clearing out" process at the axilla. Dr. Sanderson very rightly pleads that we must also consider the posterior triangle. It is important to remember that lymphatic glands may be affected by carcinoma either directly or indirectly. The glands which receive lymph directly from the infected area enlarge first, but it is only at a later period that other glands, through which the lymph has afterwards to pass, become involved. In carcinoma of the breast the lymphatic glands which are most frequently affected are those in the axilla, especially the pectoral set lying under the border of the pectoralis minor. Later in the case glands higher up, situated in the posterior triangle, become also involved. It is extremely rare for the glands above the clavicle to be affected directly. In every case of carcinoma of the breast, in order to reduce the chance of recurrence to a minimum, the axilla should be cleared, even if no enlarged glands can be felt. But if there be no evident involvement of the axillary glands, there is practically no chance that the glands in the posterior triangle are affected; so that it is undesirable to subject the patient to the increased risk of this extension of the operation. But if the axillary glands are markedly involved there is very great probability that the glands above the clavicle are also affected; in such a case there is no reasonable chance of cure unless these glands also are removed. The superficial glands lying on the cervical fascia can be readily taken away, but it is no easy matter to remove the deeper glands which lie around the subclavian vessels and under cover of the clavicle, and these deeper glands are those most likely to be affected. Yet it is undoubtedly advisable to attempt their removal in many cases where they are now left untouched. But the axillary and the supra-clavicular glands are not the only lymphatic glands connected with the breast; the lymphatics of the inner segment of the breast run to the sternal glands in the anterior mediastinum, and it is greatly owing to the fact that carcinoma of the breast usually affects the upper and outer segment of the breast that these intra-thoracic glands are so rarely involved.

LETTER-BLINDNESS.

THE case of word-blindness recorded by Dr. Hinshelwood, which will be found on another page, with the appended comments on visual memory, is of very considerable interest, and an additional form of visual defect must be accepted in which, as in a few other recorded cases, there is not only word-blindness, or loss of memory of the signification of the words of a sentence, but a failure to recognise the individual letters of which words are composed. In this instance the precision of the limits of the cerebral lesion was so exact that Arabic figures were read with perfect ease though the patient was unable to name a single English or Gothic letter. The defect proving persistent the patient, a man aged fifty-eight years, was recommended by Dr. Hinshelwood to begin to learn his letters like a child, and after some months of painful application he recovered the power of naming them. A somewhat similar condition has been observed in patients possessing a knowledge of music, the defect consisting in a loss of the power of musical expression, which has been named "amusia," in one form of which analogous to the above-mentioned case there is a loss of the power of comprehending the significance of musical notes though they can be perfectly seen. In Dr. Hinshelwood's case there was complete loss of vision in the inner part of the right and the outer part of the left retina, or right lateral homonymous hemianopsia. The chief interest of such cases as this, and of others that Dr. Hinshelwood has collected, consists in their bearing on the recondite subject of memory. It has been generally regarded as a special and distinct faculty holding good for all sorts and kinds of knowledge. Sir William Hamilton and Dugald Stewart were at one in regarding it, in the words of Stewart, as that faculty which enables us to treasure up and preserve for future use the knowledge we acquire. That a person has a good memory is in common parlance equivalent to saying he can recall any past impression on his senses; but it is obvious that this is incorrect, and that whilst there is no such single faculty as memory, memories of different kinds of impressions—as of vision, hearing, and movements—do exist, each

Digitized by Google

of which, as pathology teaches, has its own special cortical area in the brain. An intimate connexion exists between the several centres, but any one may be lost from some local lesion, whilst the others remain intact and in full functional activity. Moreover, some of these centres, as those for speech and writing, as well as the seats of the visual memory of numbers and musical notes, are probably unilateral whilst such visual memories as those of objects, places, form and colour are, as Dr. Hinshelwood observes, efficiently imprinted and stored up in the higher visual centres of both hemispheres. Therefore it would require a bilateral lesion to produce object blindness, hence its much less frequent occurrence. We must refer our readers to Dr. Hinshelwood's instructive paper for the reasons that led him in this case to believe the lesion to have been unilateral.

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

WE must offer our thanks to our contemporary the *Times* for the excellent leading article of Dec. 13th concerning the School Board and medical certificates. It is all very well for Mr. Sharp to say no slight is intended to be put upon the medical profession, but the fact remains that he has put a slight upon it in general, and in particular by refusing to consult the medical officer of the Board. If the remarks in the whole of the medical press, the leading article and correspondence in the *Times*, the caustic little dialogue in this week's *Punch*, and the refusal of sundry hospitals to give any more certificates do not overcome the pigheaded obstinacy of Mr. Sharp's committee and the Board as a whole, and lead to a rescinding of the resolution of May 30th, further steps will have to be taken. The Board makes a great point of Bible instruction. We would remind it of a notable question, "Who made thee a judge and a ruler over us?"

THE METROPOLITAN POLICE SURGEONS' ASSOCIATION.

THE eighth annual dinner of this association was held on Wednesday evening, the 18th inst., at the Criterion Restaurant. In consequence of the inability of the chief surgeon of the metropolitan police to preside, the late chief surgeon, Mr. Timothy Holmes, acted as chairman. On the conclusion of the dinner the Chairman proposed the usual loyal toasts, and then the "Navy, Army, and Auxiliary Forces," coupled with the name of Lord St. Vincent, who, in the course of his speech, referred to the successes of the Medical Staff in Burmah and at Chitral. The Chairman then proposed "The Metropolitan Police Surgeons' Association." After he had commenced, the unexpected arrival of the chief surgeon, Mr. Mackellar, was announced, and his appearance was the sequel for much cheering and hearty congratulations on recovery from his recent illness. Mr. Mackellar was requested to reply, and did so in his usual eloquent manner, his name being received with musical honours. Mr. Farr also replied, giving a history of the formation of the Association. In the absence of the Commissioners of Police, to whose kind assistance in the interests of the Association reference was made by the Chairman, the "Health of the Chief Surgeon" was proposed, and acknowledged by Mr. Mackellar. Dr. Phillips, in proposing the "Guests," made allusion to the happy relations existing between the divisional surgeons of police and the metropolitan magistrates. Mr. Newton, the magistrate of Marylebone Police-court, replied. Mr. Spurgin proposed the health of the Chairman, who, in reply, reviewed some of the events which affected police surgeons during his tenure of the office of chief surgeon. "The Medical Press" was proposed by Dr. Yarrow, and Mr. W. H. Battle, who replied, alluded to the interest which was taken by the medical press in all matters of public importance brought forward by the Association. He also expressed the especial interest which the Editors of THE LANCET took in supporting the views of such an important Association. "The Dinner Committee," proposed by the Chairman, was replied to by Mr. Spurgin, one of the secretaries of the Association, who may be congratulated on the success of a very pleasant gathering. During the evening a programme of music was provided under the direction of Mr. Herbert Schartau, assisted by Mr. John Bartlett, Mr. Wingrove Ives, and Mr. F. Russel, a ventriloquist who is well known for his clever sketches.

CONDITION OF THE BLOOD IN PURPURA.

IN the *Presse Médicale*[1] is an essay on Purpura Hæmorrhagica by Professor Hayem in which the condition of the blood in this disease is recorded, and describing investigations made by him. Professor Hayem states that in this variety of purpura the blood possesses the following characteristics. 1. There are no appreciable anatomical modifications in the red corpuscles, except, perhaps, a diminution or absence of those corpuscles of exudation which are produced by the disintegration of the red cells when preparations of blood are submitted to the action of solvents. 2. There is a considerable diminution in the number of hæmatoblasts; those that remain are often considerably increased in size. 3. There is no constant alteration in the number of leucocytes. In one case only was the number of white cells increased. 4. The coaguability of the blood was normal. The fibrous reticulum remained invisible, although, on the other hand, it was formed of fibres of an unusually large size. 5. Transudation of serum was absent from the clot, which latter possessed only a feeble power of contraction. Thus, the two characteristic and constant pathogenic properties of the blood appeared to be the scarcity of hæmatoblasts and the absence of transudation of serum after coagulation. The diminution of the hæmatoblasts in purpura would partially explain the production of hæmorrhages (epistaxis, menorrhagia, &c.), as these bodies play an important *rôle* in the arrest of bleeding and the clotting of the blood. It is probable that in certain diseases attended with purpura the diminution in the number of hæmatoblasts is in consequence of a destruction of these elements. It is possible that the state of the blood may be dependent upon a faulty elaboration of nutrient material, or upon the introduction into the blood, under the influence of digestive disorders, of toxic substances having the property of producing changes in the hæmatoblasts.

PROSECUTIONS FOR SELLING DRUGS OVER THE PRESCRIBED STRENGTH.

THE law is clear in regard to the sale of drugs, but not so easily interpreted is it in regard to food, although both, of course, come under the provisions of one Act. In the former case the requirements of the Pharmacopœia are to be complied with, but in the latter no rules are laid down as to what should be the standard quality of the various articles of food. Drugs are required to be sold containing neither a deficiency nor an excess of the active ingredient, but the precise quantity; foods are not to be attenuated, or, in other words, the seller is not to practise a fraud upon the purchaser, nor is he to offer for sale any article for consumption containing ingredients that are injurious to health. The pharmacist, therefore, commits just as serious a breach of the law if he supplies drugs which are of greater strength than is asked for, or in excess of the strength prescribed by the Pharmacopœia. (Parenthetically, imagine a London milkman found guilty of

[1] 1895, p. 233.

Digitized by Google

selling milk containing an unusual proportion—say 20 per cent.—of cream!) Four cases of this kind occurred recently at Birmingham. In two of the cases tincture of iodine was sold containing 150 per cent. of iodine and 50 per cent. of potassic iodide in excess of the quantities set forth by the British Pharmacopœia; in the other two cases samples purporting to be tincture of aloes contained 40 per cent. of solid ingredients and 50 per cent. spirit in excess of the formula. With the exception of one case—viz., that of aloes, in which it appeared the inspector purchasing the samples had entered it as "compound tincture"—fines were inflicted and costs imposed. It is not probable in these particular instances that any harm would have resulted despite the great excess of ingredients found on analysis by Dr. Alfred Hill, the medical officer of health; but if the same laxity had been extended to other drugs the results might obviously have been very serious indeed. The majority of these offences are probably committed when a purchaser buys drugs on his own responsibility, and not when he is under the direction of a medical adviser. On the whole the record of offences of this sort, on the part at any rate of respectable chemists and druggists, is a very satisfactory one; theirs is a business which requires constant care, and no one better than themselves know it and realise it. Still, the cases which do occur from time to time should not escape the notice of the medical profession, who should, therefore, keep a constant watch and some sort of check on the medicines which druggists make up for them.

A CASE OF TRICHINOSIS.

A CASE of trichinosis is reported by Dr. Edgar Garceau of Boston in the *Boston Medical and Surgical Journal* of Nov. 21st of this year. Apart from the rarity of the disease the case presents several points of interest. The patient was a German thirty years of age. About the end of March he ate some smoked ham. Many of his friends who also ate some of the same ham were taken violently ill the day after with severe vomiting and purging, but they all eventually recovered. He himself was not taken ill at once, which fact he thought was accounted for because he ate only a very small piece. For two weeks, however, he felt ill, complaining chiefly of backache and pain in the limbs. When seen on April 12th the muscles of the calves of his legs and of the arms and back were sore. The bowels had been regular, and there had been no symptoms of intestinal irritation. On examination a few red spots were seen on the abdomen, which disappeared on pressure. The spleen was of normal size. The temperature was 103·5° F. The face was red, the eyes bulging in the sockets, and the conjunctivæ red and swollen and raised above the level of the corneæ. The next day he was worse, and he passed three very loose stools, watery, and of pea-soup consistency. The following day there was vomiting, the temperature was 104°, and the voice husky. He gradually grew weaker and died on April 17th. Only a partial necropsy was allowed, but no difficulty was experienced in demonstrating the characteristic trichinæ. At the early stage of the case the diagnosis and the resemblance to enteric fever was remarkable. The prodromata of malaise, backache, and pain in the limbs, the gradually rising temperature, the characteristic typhoid stools, and the rose-coloured spots all suggested enteric fever as the probable diagnosis. The pains in the limbs, however, became so severe that morphia had to be administered for their relief, and then the diagnosis of trichinosis was more assured. We have, therefore, the history of the case and the period of incubation (two weeks) during which time the trichinæ were migrating from the intestines to the muscles. If the patient had eaten a good deal of the ham it is probable that he would have escaped, as the others did, by the violent vomiting and purging. Dr. Garceau suggests that a cathartic should be given in future doubtful cases to clear out the parasites. In this patient's case all the trichinæ swallowed had a chance to propagate, and the number so propagated may be inferred when it is said that a single female trichina may produce more than a thousand embryos. The ocular symptoms were suggestive; the œdema of the conjunctivæ was very marked, and was the first symptom which aroused suspicion as to the nature of the case. The implication of the laryngeal muscles, as evidenced by the husky voice, was also characteristic.

THE "SUN" AND CHARGES AGAINST A MEDICAL MAN.

ON Thursday, Dec. 12th, the case of Ady *v.* Cadett came before Mr. Vaughan. Mr. Cadett is a journalist, who, it was alleged, had published a defamatory libel in the columns of the *Sun* upon one J. C. Ady, a medical man. Mr. Ady having been cross-examined, Mr. Vaughan stopped the case and dismissed the summons. As we believe further proceedings are pending we refrain from any comment.

MUSCULAR ATROPHY AND GENERAL PARALYSIS.

IN a recent number of the *Münchener Medicinische Wochenschrift* Dr. Riebeth publishes a case of which an abstract appears in the *Neurologisches Centralblatt*. The patient had gonorrhœa in 1884, but had not apparently had syphilis. His nervous symptoms began in 1893, and consisted of weakness, giddiness, noises in the ears, and inability to work. There were also considerable excitability occasionally verging on violence, an indifferent manner and emotional tendency. He was found to have unequal pupils, loss of reaction to light, absent knee-jerk, articulatory disturbance, and impairment of intelligence. After his discharge there were increase in his psychical symptoms, diminution in his appreciation of pain, and other disturbances of sensibility. In March, 1894, the triceps and trapezius on each side were found to be wasted, and this wasting gradually increased, so that at the end of May, 1894, there was much atrophy of the right trapezius and latissimus dorsi, and of the pectorals and triceps on both sides. There was slighter atrophy of the left trapezius and of the serratus, rhomboid, deltoid, and infra-spinatus on the right side; while in the left latissimus, the flexors of both forearms, the rotators of the upper arm on the right side, the right supra-spinatus, and the abdominal muscles the atrophy was very slight, but distinct. In these muscles there was diminished response both to faradaism and voltaism. It is evident that in this case there was first affection of the posterior columns with a disturbed cerebral state, while the condition underlying the muscular atrophy developed later. The condition somewhat resembled that in the juvenile form of muscular dystrophy, but here the muscular atrophy probably depended upon changes in the spinal cord.

HUNTINGTON'S AND CONGENITAL CHOREA.

AT the recent meeting of the Vienna *Verein für Psychiatrie und Neurologie*[1] Dr. von Sölder showed a case of Huntington's chorea. The patient was a woman fifty-two years of age who became affected with chorea seven years previously, but her intelligence was still good. The eye muscles, contrary to the usual rule, took part in the contractions. Speech was much interfered with, and there was but little voluntary control of the choreic movements. These, however, ceased during sleep. There was considerable muscular weakness, and the reflexes were distinctly increased. The patient was the granddaughter of a woman who became choreic at the age of fifty and died in her fifty-third year. Of her seven sons, all (including the father of

[1] Neurologisches Centralblatt, 1895, p. 1149.

Digitized by Google

the patient shown), except the eldest, suffered from chorea about the fiftieth year. The patient had four sisters, and of these one suffered from chorea at the age of forty-nine, while two others were mentally affected. A son of the patient was healthy. Another case was also shown, one of so-called "chronic congenital chorea" in a girl aged sixteen. The contractions were noticed immediately after birth, and the patient did not begin to walk until she was four years old, and it was only at the age of eight that she could walk alone. She was also late in speaking. She used her hands with difficulty, but her condition showed a slow but gradual improvement. Voluntary movement increased the contractions. The knee-jerk was slightly increased, but with the exception of a small degree of weak-mindedness the general condition was fairly good. The case, according to Dr. von Sölder, is really one of cerebral diplegia, and, as was recently pointed out in our columns, this is almost invariably the actual condition in cases of so-called congenital chorea; so that the term is probably a misnomer, and the movements would be more correctly described as those of athetosis.

DR. RENTOUL explains in a circular that his opposition to five successive Bills since 1890 has cost him, "out of his own private means," £321 15*s.* 9*d.* Dr. Hugh Woods established a fund to repay Dr. Rentoul, and succeeded to the amount of £50. Mr. Colin Campbell succeeded in the same way to the amount of £30. In 1894 the branch committee of the Lancashire and Cheshire Branch refunded him £37 17*s.* 2½*d.* These sums amount in all to £117 13*s.* 2½*d.*, leaving him still £204 2*s.* 6*d.* out of pocket.

THE death, on the 17th inst., is announced of Mr. Daniel Ambrose, M.D., Q.U.I., L.R.C.S.I., &c. Dr. Ambrose was member of Parliament for South Louth. He belonged to the anti-Parnellite party, and at the last General Election defeated another medical man, Mr. J. G. Fitzgerald.

WE regret to hear of the death of Dr. Fauvel, of Paris, whose reputation as a laryngologist is of world-wide fame. His work on Tumours of the Larynx is one of the standard works on the subject.

THE ASHANTI EXPEDITION.

VERY great activity has been displayed on the Gold Coast in disembarking stores and in preparing for the advance of the troops on Kumasi. One of the main difficulties in the present expedition, as on the last occasion, has been the transport. There is no animal or vehicular transport in the country, and everything has to be carried by native bearers. Great care has been taken in providing and organising a sufficient force of these, and the transport work went on very satisfactorily as far as Mansu, but owing to the difficulty in procuring food in the country beyond, and the desertion of a number of the native carriers, a block occurred from the accumulation of stores at that station. This will, however, soon be overcome. As in our Indian warfare, and following the course adopted in the last Ashanti campaign, rest camps have been provided along the line of route. Eight of these have been constructed, and a field telegraph will be completed between Cape Coast Castle, which is the base, and Prahsu. The postal service which has been organised between these stations is working well. The distance, it may be mentioned, of Prahsu from the base is about eighty miles. A pontoon bridge is being constructed over the Prah, but the work is temporarily delayed pending the arrival of requisite materials, and cannot be completed for many days. Three canoes, each capable of carrying thirty men, have been constructed for the passage of the river.

Meanwhile a hospital for the troops is being provided at Connor's Hill, which will afford accommodation for five officers and seventy-five men, and a bearer company of 600 men has been organised for the transport of the sick. We are not told, by the way, what the means of transport of the sick and wounded will be, whether stretchers or canvas cots or hammocks from the naval ships, or all of these. Surgeon-Captain Eckersley has started to provide for the establishment of a hospital, at Prahsu for the troops on the march. In addition to the land hospitals at the base there will, of course, be the large amount of accommodation afforded by the floating hospital, the *Coromandel*, which has been specially fitted up for the purpose; and with the steam transports and other communications between the Gold Coast and this country there should be no difficulty in arranging for the transit of invalids.

Whilst preparations are being made for the advance of the force along the line of route from Cape Coast Castle across the Prah to Kumasi, a movement is also to be made contemporaneously with that of the expeditionary force from the coast, from the north, by a large force of constabulary and a detachment of Houssas and two Maxim guns. This latter force will, it is understood, proceed to the Nkoranza country, and thence threaten, and advance if necessary, on the Ashanti capital.

The subordinate chiefs in the interior of the colony are understood to be very favourable to the expedition, and have proffered their services and large detachments of bearers. Samory, the Mahommedan chief of a large warlike tribe in the vicinity of Ashanti, who has a powerful army, is understood to be also favourable to the British enterprise.

The belief entertained on the Gold Coast is that the chiefs of the Ashantis are determined on fighting. It is rumoured that Prempeh will be deposed and replaced by his mother, a woman of fortitude and masculine character, who is strongly inimical to the whites. Be this as it may, the expedition may have to encounter some unforeseen difficulties and hard fighting before the troops succeed in capturing the Ashanti capital. The topographical difficulties and dense bush for obvious reasons offer very favourable conditions for Ashanti warfare. The country is well adapted for raids and surprises and sudden attacks from numerous small and concealed bodies of men.

The health of the troops on the Gold Coast is reported to be excellent. The present season is favourable in this respect for the expedition, which cannot, however, it is believed, start for Kumasi for some time. We hope that when it does start the march to the Prah may not be protracted by any defective arrangements or other obstacles, for the country and bush are very malarious, and that when the expedition has accomplished its work by penetrating to the capital and securing its political objects the force may effect its return march before the rains set in. In that case there is no reason to suppose that the risks to health and life should prove greater than on the occasion of our last war with Ashanti. Everything depends upon the exercise of forethought in providing for the requirements of the force and in safeguarding their health, as far as practicable, by good sanitary arrangements. The previous experience of those who have to conduct the arrangements in these respects affords the best guarantee that we can have of their being properly carried out.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on the 12th inst., the President, Mr. Christopher Heath, being in the chair.

A further report dated Nov. 15th was presented from the Board of Examiners in Dental Surgery. The chief recommendation was that an examination in mechanical dentistry, chemistry, physics, and metallurgy should form the first examination for the licence. The report was referred to a committee of the Council.

Dr. Arthur P. Luff was appointed an Examiner for Part I. of the Examination in Public Health.

Two cases of alleged misconduct on the part of Members were considered.

The President stated that the Deputation Committee, at a meeting held on the 2nd inst., had determined to further postpone their report to the Council, as one of the subjects referred to their consideration had been selected by the

Digitized by Google

Council for reference to the meeting of Fellows to be held on Jan. 2nd, 1896.

The President, on behalf of himself and the Vice-Presidents, reported the delivery of the Bradshaw Lecture, on the 5th inst., by Mr. N. C. Macnamara, the subject of the lecture being, "Infective and Tubercular Osteitis as Causes of Arthritis in Childhood and the Importance of Early Treatment." The best thanks of the Council were accorded to Mr. Macnamara for his lecture, and he was requested to publish it.

A letter of the 22nd ult. from Mr. Frank Marshall, honorary secretary of the Newcastle-on-Tyne Dental Hospital, applying for the recognition of that institution by the College for the purposes of teaching, was referred to the Board of Examiners in Dental Surgery.

A letter was read, dated the 20th ult., from Mrs. E. Garrett Anderson acknowledging the receipt of the letter informing her of the reply of the Council to the memorial from the London School of Medicine for Women, and expressing the belief that the memorialists, while much regretting the decision, will greatly value the assurance contained in the resolution of the Council that, had the matter rested solely with them, the prayer of the memorialists would have been granted.

A letter was read, dated the 27th ult., from Dr. Liveing reporting the adoption by the Royal College of Physicians of London, on the 22nd ult., of the report, dated Nov. 11th, 1895, of the delegates on the arrangements of the examinations under the five years' curriculum, with the following rider—viz: "That the College of Surgeons be informed that this College would consider it an improvement if pharmacology were placed with therapeutics under the head of medicine, instead of being accorded a distinct position as a subject separate from medicine, surgery, and midwifery." The Council thereupon expressed their approval of the suggested alteration.

A letter was read from Mr. Thomas Bryant reporting the proceedings of the General Medical Council at their late session. The letter was received, and the best thanks of the Council were given to Mr. Bryant for his services as representative of the College.

THE BATTLE OF THE CLUBS.—XIV.

WE have received a copy of the "Rules, Code of Etiquette, &c., of the Fermanagh Medico-Ethical Association." The objects of the Association are as follow:—

The promotion of social and professional intercourse, of mutual protection and coöperation, of opportunities to enable members to obtain the advice and united support of the local profession.

To obtain increased and more efficient representation for general practitioners on the General Medical Council, and of medical men in Parliament.

To arbitrate in disputes between members of the Association.

To support and protect the honour and dignity of the profession, and to promote honourable practice, to suppress advertising, or other unfair methods of competition, unqualified and irregular practitioners.

To watch Parliamentary proceedings affecting the profession and give the members the opportunity of expressing their views thereon.

To consider and take action upon the relations of medical officers with all forms of club practice, and with regard to Poor-law and other official appointments.

To circulate a Code of Ethics and information as to various scales of medical tariff amongst the members.

To promote the improvement of medical fees, and the adoption of some "wage" or "valuation" limit for those entitled to free attendance from Poor-law medical officers.

To establish, maintain, and circulate amongst the members a patients' black list.

WITH REGARD TO CLUB PRACTICE.

To enforce a wage limit.

To insist on a medical examination for all new members and an examining fee.

To raise the usual rate of subscription for females and juveniles.

To safeguard the tenure of office by a three months' notice on either side.

The code of medical etiquette set out by the Association is, with some additions, that adopted by the Manchester Medico-Ethical Association. It contains directions for nearly every conceivable point that can possibly arise in the relation of practitioners to patients or to one another. A very full and carefully drawn-up table of fees is given. With regard to the question of club practice the Fermanagh Medico-Ethical Association does not seem to have made up its mind. Appended to the rules and code are the rules adopted for club practice in Cork, and those drawn up by the Eastbourne Provident Medical Society, of which latter a full account appeared in THE LANCET of Oct. 5th, 1895. In the matter of Cork, the Fermanagh Medico-Ethical Association consider that the wage limit—£200 a year—is too high, and that the practice of charging for a family irrespectively of numbers is not nearly so desirable a practice as charging for each member of a family. In these two opinions we cordially agree. For a man with an income of £200 a year to belong to a club is absurd, or would be in England; but the question of medical attendance in Ireland stands upon a somewhat different footing. In our opinion, the club difficulty is best solved by the formation of provident medical associations like those at Eastbourne and Bexhill, and the Portsmouth Medical Union.

CHELSEA HOSPITAL FOR WOMEN.

THE CASE OF MR. O'CALLAGHAN.

ON Wednesday afternoon a special meeting of the governors of the Chelsea Hospital for Women was held in the board-room at the hospital, under the chairmanship of Lord Glenesk. The purpose of the meeting was "to consider the propriety of the governors dispensing with the services of a member of the honorary medical staff, and to pass a resolution thereon." There was a fair attendance.

At the opening of the proceedings, Mr. O'CALLAGHAN asked if Mr. Charles Russell, his solicitor, who was helping him in the case, might be allowed to speak for him. This was not granted at first, but Mr. BURDETT-COUTTS, M.P., appealed to the council in the interests of fair play. He said that the case of Mr. O'Callaghan should be fully and fairly stated before the governors proceeded to a decision on the subject.

The CHAIRMAN said that this need not be made a formal matter of motion. Mr. Russell had no real *locus standi*, but as there was a disposition on the part of some of the governors it would be advisable to admit him, and he would take it upon himself to do so.

Mr. RUSSELL was then admitted into the room.

The CHAIRMAN said that the council had considered themselves obliged to summon this meeting to decide upon the council's conduct in a matter affecting the hospital. Rumours had got abroad about the hospital, as if some scandal had occurred in it connected with the patients and with matters of that kind. That was not the case. He had only to repeat the strong terms of praise he used when they last met regarding all responsible for the carrying on of the hospital, including of course Mr. O'Callaghan, of whose skill no one had ever had the slightest doubt. Mr. O'Callaghan had circulated a pamphlet in which he represented himself quite unfairly as a victim, not because of professional jealousy but because he was a reformer, and that he was meeting the usual fate of reformers—martyrdom. His reform consisted of interfering with the general law of the hospital by forbidding the resident medical officer to interfere with his (Mr. O'Callaghan's) patient. It was a question of hospital discipline, not of Mr. O'Callaghan's efficiency at all. Mr. O'Callaghan had found fault with the resident medical officer for touching the dressings of a patient. That was a medical question upon which only medical authorities could determine; but immediately after this the council found that the case had not been entered up in the books; that the woman had died on June 18th; and that on the 26th, when the weekly board meeting was held, there was no notice of the death, and the case was not written up. There again they thought Mr. O'Callaghan had been in default. Mr. O'Callaghan virtually attributed the death to the resident medical officer—to a secondary shock received from his treatment. That was a serious allegation; and the council found, upon further inquiry, that Mr. O'Callaghan had invited Mr. Bland Sutton and Dr. Duncan to state their opinion in a way that both gentlemen considered a violation of medical etiquette. It had been his (Lord Glenesk's) painful duty to inform Mr. O'Callaghan that he had lost the confidence of the board, and it had been thought he would at once resign. Mr. O'Callaghan did not take that course, but called for further investigation, and Mr. Burdett-Coutts made his appearance on the field of battle and suggested a *modus vivendi*, to which they were all most ready to listen. But the whole medical staff then intimated that they

Digitized by Google

could not possibly work with Mr. O'Callaghan. In all this matter he would point out that the council had been pretty nearly unanimous throughout; and they were certainly unanimous now, and the medical staff were also unanimous. Before the medical staff made that intimation the council had already asked Mr. O'Callaghan to resign; and therefore the council were not, as some people had said, dictated to by the medical staff at all. The death of the patient Sarah Welman was in no way regarded as accountable to the action of the resident medical officer. On the other hand, the staff considered that he would have been neglectful of his duty if he had acted otherwise than as he did. Mr. Burdett-Coutts and Mr. Dyer Edwards interviewed the medical staff, hoping to find some way out of the matter without calling for the resignation; but the staff replied that they were unable to assent to the suggestion of withdrawal and apology. Upon that the council resolved—Mr. Burdett-Coutts withdrawing and two other gentlemen not quite agreeing—not to rescind the motion calling for Mr. O'Callaghan's resignation. Messrs. Day, Russell, and Co. wrote on behalf of Mr. O'Callaghan that he would not resign, and the council replied that they would have to refer the matter to the governors, and that word "refer" had been twisted into meaning an arbitration. That was never intended. The council were the executive, doing the work for the hospital as well as they could, but they were never going to submit to an arbitration before lawyers. They were willing to refer the matter to two gentlemen as consultants, one to be nominated by the President of the Royal College of Physicians and the other by the President of the Royal College of Surgeons. He then narrated the circumstances which led to his (Lord Glenesk) having seen at the hospital two gentlemen nominated by the Royal Colleges of Physicians of London and Surgeons of England to assist as consultants in the matter, and read correspondence from Messrs. Day, Russell, and Co. showing how and why the help of these gentlemen had not been used. The council had never intended to offer an arbitration before which Mr. O'Callaghan could appear with distinguished leaders of the Bar, and they ultimately took the advice of Mr. Cozens Hardy, Q.C., as to their legal rights. Lord Glenesk concluded his speech by saying that the council, after eighteen meetings, and after carefully weighing everything, had come to the conclusion, very reluctantly but entirely based upon the internal regulation of the hospital, that whether Mr. O'Callaghan lost his head or whatever else was the matter with him, he could not get on with his colleagues, and so they wished him to depart from Chelsea Hospital. If this meeting decided that the executive and the honorary staff were in the wrong they would be asked to appoint another board and another staff, though both would willingly continue their services until their successors were appointed; but this meeting would either endorse their conduct towards Mr. O'Callaghan or prefer to dispense with their service.

Mr. RUSSELL, Mr. O'Callaghan's solicitor, was then heard. He said that Mr. O'Callaghan was there that day charged with some terrible things. He (Mr. Russell) had nothing to complain of in the way the chairman had put the case according to the chairman's view of it. They no doubt desired to be fair; but he thought the council had acted in the most unfair way in threatening resignation should this meeting not support them. The meeting had been told that Mr. O'Callaghan had made false charges against colleagues, that he had tried to suborn them to falsify the books. Yet the chairman said that there was nothing to arbitrate upon. After taking upon himself the responsibility for Mr. O'Callaghan not appearing before Dr. Black and Mr. Bryant, Mr. Russell said he thought the history of the dispute had been given correctly, fairly, good-temperedly, and politely in the pamphlet which had been circulated. Mr. O'Callaghan had desired to introduce a particular reform into the hospital, and the chairman said he should have gone to the board to ask authority to do it. But that missed the whole point of the case, because there were rules by which the doctor in charge of each ward was given power, as he contended, to introduce such changes. He knew there was a difference of opinion about it, but when Mr. O'Callaghan issued the order that the resident medical surgeon was not to interfere with his patient he did it in the belief that he was well within his rights. The patient was admitted on May 30th. Shortly afterwards there was a consultation about which there was now a dispute. On the one side, Mr. Bland Sutton stated that a particular operation was advised. On the other side, Mr. O'Callaghan said that a totally different operation was advised. The operation book was not written up until the woman was dead and buried. It was then brought to Mr. O'Callaghan to sign, and immediately, when it was called to his attention, Mr. O'Callaghan said he did not notice that Mr. Sutton had signed for a different operation, and he did what a man of honour would do, and the next time he met Mr. Sutton he told him that he had made a mistake and signed for the wrong thing. Mr. Sutton said, "Do you mean to say that I am a liar?" and to that rather "tread on the tail of my coat" remark Mr. O'Callaghan said, "Well, if you put it that way, you are." But did that mean that Mr. O'Callaghan tried to suborn a colleague to falsify a book? Mr. O'Callaghan now apologised heartily and sincerely for the language he used. But the charges were serious, and some impartial outsider should be asked to hear and decide upon them, which he thought was the original intention, and which would have been carried out but for the unhappy incident of the arbitrators named going and seeing a member of the board without a representative on the other side. A first impression upon an arbitrator was most important.

The CHAIRMAN said the reference had nothing to do with the council. It was simply a reference of the charges made by Mr. O'Callaghan against the resident medical officer.

Mr. RUSSELL said that the question had been raised whether Mr. O'Callaghan had the right to establish a particular rule, and so the conncil would also have been concerned. Lord Glenesk was incapable of doing an unfair action consciously; but surely where the honour and the future of a medical man of good repute were concerned, it was the commonest justice that they should put definitely in black and white the charges made against him. That was what he asked them to do, and to refer the charges to fair arbitration.

Dr. DUNCAN, senior medical officer at the hospital, asked if Mr. O'Callaghan had written or endorsed the contents of the pamphlet which had been circulated.

Mr. O'CALLAGHAN: Certainly.

Dr. DUNCAN said that the pamphlet was teeming with inaccuracies, and he went on to give extracts and to contradict them. It mentioned that the Samaritan Hospital had not a resident medical officer. He (Dr. Duncan) had it on the authority of one of the staff of that hospital that, although it did not keep a resident medical officer now, it used to do so, and the officer was dispensed with owing to circumstances totally unconnected with the treatment of patients. Moreover, all the staff lived in the vicinity of the hospital; but Mr. O'Callaghan and himself lived three miles away from the Chelsea Hospital for Women, and a patient might easily bleed to death before they could arrive. The medical staff came to the unanimous conclusion that the death of the patient in this case was in no way contributed to by the action of the resident medical officer. It was entirely false to say that the action of the medical staff forced the council to call for Mr. O'Callaghan's resignation.

Mr. BLAND SUTTON then gave his version of the incident of the signing of the operation book. He had signed it, leaving the line above his for Mr. O'Callaghan to enter his statement about it. Ten minutes before going before the committee, he met Mr. O'Callaghan, who, without discussing the case, said, "Look here, my boy, there is a way out of this difficulty for you." He replied that there was no difficulty for him. Mr. O'Callaghan said, "Tell the council you made a mistake, that your entry referred to a case in another ward," and he replied that he had had no other case, and asked, "Do you mean to say I deliberately wrote a lie in the book," and Mr. O'Callaghan said, "Yes, and I will tell the board so." He then said he would never speak to Mr. O'Callaghan again.

Mr. BURDETT-COUTTS read his letter of resignation as a member and Vice-chairman of the Council, stating that his reasons were that the Council first called upon Mr. O'Callaghan to resign upon the strength of an *ex-parte* statement, and that although it was afterwards much shaken by evidence adduced by Mr. O'Callaghan, the Council refused to rescind the resolution. In taking this latter decision the Council appeared to have accepted a second *ex parte* statement from the medical staff, which was not only injurious to Mr. O'Callaghan, but an attempt to dictate to the Council whether they should or should not retain a particular officer in the hospital. He considered that the whole matter should be referred to arbitration.

The CHAIRMAN said that Mr. Burdett-Coutts had only

Digitized by Google

been present at two out of the eighteen meetings at which this matter had been considered. His late colleagues were now unanimous.

Mr. FERGUSON said that there was nothing to arbitrate upon.

Mr. J. L. LANGMAN said that Mr. O'Callaghan had been blamed for not attending before the arbitrators; but Mr. O'Callaghan had been told that no action would be taken for two months, and so had made his arrangements to go away. He moved: "That the whole of the questions that have arisen in this matter be referred to arbitration."

Mr. O'CALLAGHAN said he wished to say a few words in reply to some of the remarks which had been made. Mr. Sutton, during the week in question, saw two cases with him of the same nature, and he (Mr. O'Callaghan) said that Mr. Sutton had mixed up the two, and when asked to sign the book on the second case he forgot. He (Mr. O'Callaghan) knew it was a mistake only—but it was Mr. Sutton's mistake. He was prepared to prove this before the arbitrators; but all these things wanted clearing up, and he was prepared to go to arbitration, for all he wanted was justice and fair play for the sake of his reputation.

Dr. TRAVERS seconded Mr. Langman's motion.

At this stage,

Mr. RUSSELL said that, to keep himself in order, he would now formally lodge a protest against the staff or their nominees voting upon this occasion, that he would ask for a scrutiny of the votes, and that he protested against the power of the governors to dismiss Mr. O'Callaghan.

Upon Mr. Russell attempting to say these words an interruption took place, booing, tapping, and sounds of disapproval proceeding from one end of the room—the end where the audience was largely composed of ladies.

The CHAIRMAN then moved: "The council, after full investigation and consideration, being of opinion that the continuance of Mr. O'Callaghan as a member of the medical staff would be incompatible with the maintenance of proper discipline of the hospital and injurious to its interests: and all the other members of the honorary medical staff having in a formal manner definitively refused to coöperate with him in the discharge of their professional duties in the hospital: it is resolved that Mr. O'Callaghan be, and he is hereby, relieved of his duties as an honorary medical officer of the hospital."

Mr. DYER EDWARDS seconded this motion.

Canon FLEMING said there was a lady present who was not credited with the number of votes to which she was entitled. That, no doubt, would strengthen Mr. Russell in his intention to have a scrutiny. He (Canon Fleming) was in favour of the motion for arbitration.

A vote was then taken, with the following result:

For Mr. Langman's motion	17
Against	106
Majority against	89

The Chairman's motion was then put to the meeting and agreed to without a further division.

The proceedings, which lasted three hours, terminated with a vote of thanks to Lord Glenesk for presiding.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual general meeting of the Association of Fellows of the Royal College of Surgeons of England was held on Dec. 11th. Mr. George Pollock, the President, occupied the chair. The minutes of the last annual general meeting were read and confirmed. The President stated that as his address practically embodied a report of the work done by the Association during the past year he would ask Mr. Percy Dunn, honorary secretary, to read it. The following is a summary of the address:—

The first business of importance which took place after the annual general meeting last year was the appointment of a sub-committee to meet and confer with a sub-committee of the Society of Fellows with respect to the election of the President of the College and other matters. Practically, the only result which ensued from this conference, which took place on Nov. 7th, 1894, was the decision, at the instance of the Association of Fellows, of the Society of Fellows to undertake a canvass of the Fellows upon the subject of the mode of election of the President. But out of this meeting of the two sub-committees the Association were led to adopt a resolution asking the Council of the Royal College of Surgeons of England to agree to a conjoint committee of the Council and the Fellows for the purpose of considering what alterations should be made in the existing charters of the College. This resolution was brought before the Fellows' meeting in January last.

Upon several occasions, both officially and unofficially, communications bearing upon College politics have been received from the Society of Members, but the committee of the Association has in all cases declined to pledge itself to any definite policy in this regard, leaving it to the members of the Association to act in their individual capacity as they may deem fit.

The Association has recorded in its minutes the loss sustained by the profession by the death of Mr. Hulke.

The next important matter was the appointment of a deputation to meet a committee of the Council of the Royal College of Surgeons of England on June 10th. At that meeting the deputation laid before the committee of the Council several proposals for the amendment of the charters and by-laws which had already received the sanction of the Association, and subsequently, at the request of the committee, placed these propositions in writing, together with the reasons that might be adduced in favour of them. These propositions have been under the consideration of the committee of the Council, but as that committee has not yet reported to the Council of the College no answer has yet been received by the committee of the Association.

The mode of conducting the proceedings at the half-yearly meetings of the Fellows, which appeared to the committee not to fulfil the objects for which the meetings were established through their initiative, has claimed some attention from the committee, as the result of which certain resolutions were forwarded to the Council of the College by the committee with a view to remedy the defects. The Council of the College has replied to the resolutions to the effect that the proceedings had been conducted in accordance with the regulations, but in answer to some further resolutions for the amendment of these regulations has contented itself with formally acknowledging the communication of the committee. It is still hoped that the action of the committee will bear fruit, but if not it may be advisable for further action to be taken.

The remainder of the report was occupied with an account of the proceedings of the committee in respect to the case of Mr. R. B. Anderson, already reported in THE LANCET, and recommending the members of the Association to coöperate with the Civil Rights Defence Committee and appoint representatives on that committee.

Mr. A. T. Norton read the auditor's report for the past year, and added that he would have great pleasure in rendering all the assistance in his power in keeping the books of the Association. The report was unanimously adopted, and a vote of thanks was accorded to Mr. Norton.

The following is the list of officers elected for the year 1895-6: President, Mr. George Pollock; Vice-Presidents, Mr. T. Holmes and Mr. W. Rivington; Treasurer, Mr. Tweedy; Auditor, Mr. A. T. Norton; Hon. Sec., Mr. H. Percy Dunn; Committee, Mr. W. Allingham, Mr. Herbert Allingham, Dr. Robert Barnes, Mr. Wickham Barnes, Mr. Bruce Clarke, Mr. John Couper, Dr. Ward Cousins, Mr. Gant, Mr. Victor Horsley, Mr. Jordan Lloyd, Mr. Mayo Robson, Mr. Manley Sims, Dr. C. Steele, Mr. George Jackson, Mr. C. B Keetley, Mr. George Helm, Mr. Mansell Moullin, Mr. Vincent Bell, and Mr. J. J. Purnell.

The case of Mr. R. B. Anderson was then brought forward for discussion, and the meeting unanimously approved of the action of the committee in this regard. Mr. Pollock Mr. Holmes, and Mr. Dunn were appointed the representatives of the Association on the Civil Rights Defence Committee. The following resolution was then passed unanimously: "That this Association adopts the reports of its committee and of the Civil Rights Defence Committee on the case of Mr. R. B. Anderson, and desires to express its thanks to the Right Hon. the Earl of Stamford as President and the public men and bodies constituting the Defence Committee who have stood forward in resistance to illegality, oppression, and persecution, and its appreciation of the action of the Council

Digitized by Google

of the College in uniting in defence of the rights of its Fellows and Members." Further, Mr. Holmes undertook to give notice of the following resolution for the half-yearly meeting of Fellows at the College in January next—viz.: "That this meeting learns with pleasure that the Council of the College are represented on the Civil Rights Defence Committee on the case of Mr. R. B. Anderson, and pledges itself to take every possible step to promote the objects of that committee."

Unanimous votes of thanks were severally passed to the officers of the Association for their services during the past year. This concluded the business of the annual general meeting.

THE SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE have received from the Society of Members of the Royal College of Surgeons of England certain "propositions for amendment of the Charters," and a statement in support of these propositions. The statement, we are informed, is published with the sanction of the President of the College.

Proposition 1 lays down "that no alterations in the constitution and external relations of the College shall be effected without the consent of the corporation."

Proposition 2 submits "that there should be an annual meeting of the corporation, to which the Council shall present a report of its proceedings, together with a duly audited balance-sheet, such report to be submitted to and approved by the meeting."

3. That the number of the Council be increased to thirty-two, and that eight of these may be Members and shall be elected by Members only.

4. No Member who has not been such for twenty years shall be eligible for a seat on the Council.

5. Members to be elected to the Council in the same way as Fellows.

6. Concerns the retirement of members on the Council.

The arguments used in the "statement" of the committee of the Society of Members are in brief as follows:—

As to the right of the Society to speak on behalf of the general body of Members, a similar body of propositions was signed by 5000 Members in 1888.

The Society of Members further suggest that the Council of the College ought to make inquiries themselves of the Members. The expense of such an inquiry is estimated at £45—i.e., £30 for postage and £15 for printing, &c.

With regard to Proposal 2, the committee think that as most of the income of the College comes from Members they ought to see how the money is spent.

"Proposal 3 contains the kernel of the whole matter." The committee consider that the College ought to show more activity in dealing with "infamous conduct," and also in suppressing unqualified practice in surgery.

As to Proposal 5, Members, as forming by far the greater part of the corporation, ought to have some share in its government. Under the new proposal the Fellows will still form three-fourths of the Council.

In conclusion, the committee earnestly ask the Council whether it would not be for the advantage of the College to allay the smouldering discontent now existing among Members.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5561 births and 3609 deaths were registered during the week ending Dec. 14th. The annual rate of mortality in these towns, which had been 17·9 per 1000 in each of the two preceding weeks, declined again last week to 17·8. In London the rate was 17·5 per 1000, while it averaged 17·9 in the thirty-two provincial towns. The lowest rates in these towns were 10·9 in Croydon, 11·3 in Brighton, 12·2 in Portsmouth and in Halifax, and 12·6 in Huddersfield; the highest rates were 20·4 in Manchester and in Norwich, 21·0 in Bolton, 21·7 in Blackburn, 22·8 in Liverpool, and 25·5 in Salford. The 3609 deaths included 524 which were referred to the principal zymotic diseases, against 529 and 561 in the two preceding weeks; of these, 198 resulted from measles, 92 from diphtheria, 79 from whooping-cough, 56 from scarlet fever, 53 from "fever" (principally enteric), 43 from diarrhœa, and 3 from small-pox. No fatal case of any of these diseases occurred last week in Brighton; in the other towns they caused the lowest death-rates in Croydon, Derby, Birkenhead, Burnley, and Preston, and the highest rates in Norwich, Liverpool, Blackburn, and Salford. The greatest mortality from measles occurred in Manchester, Birmingham, Norwich, Salford, and Blackburn; from scarlet fever in Hull and Birmingham; from whooping-cough in Salford, Liverpool, and Cardiff; and from "fever" in Norwich, and Sunderland. The 92 deaths from diphtheria included 63 in London, 4 in West Ham, 4 in Birmingham, 3 in Leicester, and 3 in Newcastle-upon-Tyne. Two fatal cases of small-pox were registered in Hull, and 1 in London, but not one in any other of the thirty-three large towns. There were 89 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 14th inst., against 89, 79, and 87 at the end of the three preceding weeks; 18 new cases were admitted during the week, against 20, 9, and 18 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2800, against 2807, 2799, and 2805 on the three preceding Saturdays; 329 new cases were admitted during the week, against 296, 325, and 312 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 447 to 264 in the five preceding weeks, were again 264 last week, and were 208 below the corrected average. The causes of 50, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Salford, Bradford, Leeds, Newcastle-upon-Tyne, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Burnley, Blackburn, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·4 and 19·5 per 1000 in the two preceding weeks, declined again to 18·9 during the week ending Dec. 14th, but exceeded by 1·1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·3 in Paisley and 15·4 in Edinburgh to 26·0 in Greenock and 29·2 in Perth. The 546 deaths in these towns included 24 which were referred to whooping-cough, 17 to diarrhœa, 10 to measles, 8 to scarlet fever, 5 to diphtheria, 4 to "fever," and not one to small-pox. In all, 68 deaths resulted from these principal zymotic diseases, against 49 and 67 in the two preceding weeks. These 68 deaths were equal to an annual rate of 2·4 per 1000, which was 0·2 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased from 10 to 19 in the three preceding weeks, further rose to 24 last week, of which 15 occurred in Glasgow, 4 in Dundee, and 3 in Aberdeen. The 17 deaths from diarrhœa showed a decline from the numbers recorded in recent weeks, and included 7 in Glasgow and 4 in Dundee. The fatal cases of measles, which had been 1 and 6 in the two preceding weeks, further rose to 10 last week, of which 5 occurred in Glasgow and 5 in Greenock. The 8 deaths from scarlet fever corresponded with the number in each of the two preceding weeks, and included 5 in Glasgow and 2 in Aberdeen. The fatal cases of diphtheria, which had increased from 3 to 10 in the three preceding weeks, declined again to 5 last week, of which 2 occurred in Aberdeen and 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 107 and 132 in the two preceding weeks, declined to 97 last week, and were 54 below the number in the corresponding week of last year. The causes of 37, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·1 and 20·1 per 1000 in the two preceding weeks, rose again to 22·8 during the week ending Dec. 14th. During the past eleven

Digitized by Google

weeks of the current quarter the death-rate in the city has averaged 24·0 per 1000, the rate during the same period being 18·0 in London and 17·2 in Edinburgh. The 153 deaths registered in Dublin during the week under notice showed an increase of 18 upon the number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against 10 and 6 in the two preceding weeks; of these, 3 resulted from "fever," 3 from diarrhœa, 1 from diphtheria, 1 from whooping-cough, but not one either from small-pox, measles, or scarlet fever. These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 2·7 in London and 0·8 in Edinburgh. The deaths referred to different forms of "fever," which had been 3, 4, and 1 in the three preceding weeks, rose again to 3 last week. The 3 fatal cases of diarrhœa showed a further increase upon the numbers recorded in recent weeks, while the mortality from whooping-cough showed a decline. The 153 deaths in Dublin last week included 28 of infants under one year of age, and 39 of persons aged upwards of sixty years; the deaths of infants showed a slight further decline from those recorded in recent weeks, while those of elderly persons showed an increase. Five inquest cases and 3 deaths from violence were registered; and 54, or rather more than a third, of the deaths occurred in public institutions. The causes of 13, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL KNOX has been appointed to the Charge of the Cambridge Hospital, Aldershot, in succession to Surgeon-Lieutenant-Colonel Smith, under orders for India. Surgeon-Captain Cockerill has been posted to Dover. The following officers have embarked for a tour of service in India since our last issue:—Surgeon-Majors Hubbard, Wight, Dundon, Beamish Powell, and Sandiford, and Surgeon-Lieutenant Williams.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain J. G. Hojel is appointed to be Professor of Materia Medica and Pharmacy at the Grant Medical College, Bombay. Surgeon-Captain G. B. French, Personal Assistant to the Principal Medical Officer of the Bengal Command, is to hold Civil Medical Charge of Naini Tal, in addition to his military duties, during the absence on leave of Surgeon-Major W. H. Cadge. Surgeon-Major F. S. Peck is reappointed to be Civil Surgeon of Muzaffarpur. Surgeon-Captain A. G. Hendley, Civil Surgeon, on return from the leave on medical certificate granted him by the Government of India, is posted to the Balaghat District. Surgeon-Lieutenant-Colonel J. Moran, Civil Surgeon, on return from furlough, to the Gorakhpur District, and Surgeon-Major G. M. Nixon, Civil Surgeon, on return from furlough, to the Jhansi District; Surgeon-Major D. F. Barry, Civil Surgeon, is transferred from Gorakhpur to Moradabad; Surgeon-Captain L. G. Fischer, Civil Surgeon, from Moradabad to Budaun; Surgeon-Major G. A. Emerson, Civil Surgeon, from Jhansi to Dehra Dun; and Surgeon-Captain J. M. Cadell, Supernumary Civil Surgeon, from Dehra Dun to Kheri.

NAVAL MEDICAL SERVICE.

Surgeon W. Bett has been appointed to the *Halcyon*.

VOLUNTEER CORPS.

Artillery: 1st Essex (Eastern Division, Royal Artillery): Surgeon-Lieutenant T. E. Stuart to be Surgeon-Captain. 9th Lancashire: Surgeon-Lieutenant A. Jones resigns his commission. *Rifle:* 3rd Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment): Berkeley George Andrew Moynihan, M.B., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Lancashire Fusiliers: Surgeon-Lieutenant R. Mitchell, M.D., to be Surgeon-Captain. 3rd (Morayshire) Volunteer Battalion Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): Surgeon-Captain G. H. Mackay, M.B., resigns his commission.

THE HOSPITAL SHIP FOR ASHANTI.

The *Coromandel*, which was fitted out in this country as a hospital ship, and recently sailed with the Special Service Corps and other troops and a draft of the Medical Staff Corps for the Ashanti expedition, has ere this reached her destination on the Gold Coast. The vessel, which is of 4358 tonnage and belongs to the P. and O. Company, should prove a very efficient floating hospital, according to the description that has been given of her—in the *Army and Navy Gazette* for example. The accommodation on the mess decks is for 350 men, with saloon cabin accommodation for forty officers. The hospital wards, which are spacious, well lighted, and ventilated, are painted a very pale green and fitted with ninety swinging iron cots, room being left for 100 canvas cots to be also slung if required. The ship is furnished with electric lighting throughout. The hospital wards are supplied with punkahs, and twelve lascars embarked as punkah pullers. Captain Wheler, who commands the *Coromandel*, was in charge of one of the transports employed in the Suakin expedition. The accommodation is excellent and the lighting and ventilation good. In addition to numerous port-holes, hatches, and skylights, the ship is fitted with Edmund's extraction system with specially constructed shafts for the removal of vitiated air from between decks and compartments. Arrangements for hospital cooking, over and above the usual cooking galleys, a condensing apparatus capable of supplying upwards of 3000 gallons of water per diem, a well-fitted laundry, bath-rooms, ice-making machine and ice-room, and soda-water manufacturing apparatus have been supplied, and the hospital sanitary arrangements have been carefully carried out. There is also an operating-room, furnished, of course, with the latest instruments and appliances, and a large dispensary. Quarters are also provided for the medical staff and for three lady nurses, a portion of the saloon being screened off and set apart for their use.

AN ELEMENTARY VETERINARY MANUAL.

We have received a copy of a small work entitled "An Elementary Veterinary Manual,"[1] for the use of officers attending veterinary classes. The author is Surgeon-Captain Bruce Seton of the Indian Medical Service, and the book forms one of Messrs. Gale and Polden's Military Series. We are always glad to welcome works by medical men which range beyond our own professional limits, and we are not surprised at an officer of the Indian Medical Service, who has been in charge of a Lancer regiment, devoting his spare time to a subject of such importance to cavalry officers. The book is simply and carefully written; its basis consists of notes taken at lectures in the Army Veterinary School, Aldershot, and these have been supplemented by notes and extracts from well-known handbooks. The book will no doubt be well received by officers in India, and will be very useful to those going through the army veterinary courses.

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force:—*North-Eastern District: Artillery:* 1st North Riding of Yorkshire Volunteer Artillery (Western Division, Royal Artillery): Surgeon-Lieutenant-Colonel Thomas R. Pearson, M.D. *North-Western District: Rifle:* 5th Volunteer Battalion the Cheshire Regiment: Surgeon-Major Seymour H. Munro, M.D., retired. 2nd Westmoreland Volunteer Battalion the Border Regiment: Surgeon-Major George William Brumwell.

Herr Dowe, whose invention of a bullet-proof coat gave rise to a good deal of interest and attention, recently died at Wiesbaden from pulmonary phthisis.

[1] An Elementary Veterinary Manual, by Surgeon-Captain Bruce Seton, I.M.S. London: Gale and Polden. 1895. Price 2s. 6d.

FOOTBALL CASUALTY.—On the 16th inst., at Chelmsford, during a match, Chelmsford against Colchester Garrison, a player fractured his right leg, and was taken to the Chelmsford Infirmary.

METROPOLITAN ASYLUMS BOARD.—An extraordinary meeting of the Board will be held to-day (Saturday) at 12 noon to consider the question of reopening the Gore Farm Hospital for the reception of convalescent fever patients. Mr. Brass will move:—"That the Small-pox Hospitals Committee be instructed to forthwith make arrangements for opening so much of the Gore Farm Hospital for the reception of scarlet fever convalescing cases as may be found necessary and practicable."

"Audi alteram partem."

THE HARD CASE OF MR. LIONEL SMITH.

To the Editors of THE LANCET.

SIRS,—The case of Mr. H. Lionel Smith, whose unjust treatment by the Government of Western Australia you commented on in your issue of Feb. 9th, has, we are glad to say, assumed a more hopeful aspect. After an eight years' struggle with what *Truth* designated as "bitter persecution," Mr. Smith found himself practically ruined and unable to obtain redress in Australia. Fortunately, however, we have in Mr. Chamberlain a Minister who acts promptly. On Aug. 8th he sent a courteous reply to an official letter on Mr. Smith's case from the Royal College of Physicians of Ireland, and this week Mr. Smith has received the offer of the appointment of district surgeon in Zululand from the Colonial Office. The salary is small, but it will enable Mr. Smith to start once again on his professional career. To do this, however, he is urgently in need of funds to meet expenses which have been incurred for the education of his children, now all but completed, and to provide for the passage and outfit of his wife and two youngest children. If prompt and substantial relief is not forthcoming we see no alternative but the workhouse for Mr. Smith and his family; but, on the other hand, if he is enabled to accept the post which has been offered him, he will have the opportunity of making a provision for them. In the eight years which have elapsed since his dismissal Mr. Smith has exhausted all his own resources, hence he is reluctantly compelled to allow this appeal to be made, and we cannot but think that there must be those within and outside the profession both able and willing to help under circumstances so urgent and yet so temporary.—We are, Sirs, yours faithfully,

JAMES F. GOODHART,
Dec. 17th, 1895. F. DE HAVILLAND HALL.

*** We have undertaken to receive and acknowledge subscriptions (vide p. 1592).—ED. L.

A PLEA FOR THE PASTEUR TREATMENT OF HYDROPHOBIA.

To the Editors of THE LANCET.

SIRS,—Having recently had a child bitten by a rabid dog brought to me I advised the parents to send it to the Pasteur Institute. Unfortunately, the poor little thing died. The anti-vivisectionists have commenced one of their usual energetic campaigns, and in the local papers endeavour to damage my professional reputation and prospects. I am asked by some neighbours why I recommend patients to resort to the Pasteur treatment for rabies. My answer is as follows, and I should be glad if you would comment on it and correct it if wrong. Hydrophobia has been recognised for centuries as one of the most fatal and intractable diseases. Up to the year 1880 every conceivable plan of treatment had been tried, and none proved in the least effectual. Of every 100 persons bitten by (presumably) mad dogs, from 20 to 70 developed hydrophobia; of these (20 to 70) rabid people everyone died and suffered horrible agony. In 1886 the Pasteur Institute was opened in Paris. Up to the present over 17,000 persons have been treated there for rabies. The total deaths have been 283, according to the anti-vivisectionists—that is, 1·66 per cent. Every one of the 283 who developed hydrophobia died in spite of every effort to save them. If these 17,000 persons had not been treated by the Pasteur method at least 30 per cent.—that is, 3200—would have developed hydrophobia and would have died. At the lowest calculation, then, some 3000 lives have been saved by the Pasteur treatment in ten years, or 300 a year, from a most terrible death. The anti-vivisectionists say that the Pasteur treatment causes hydrophobia. If this were true the deaths in 17,000 cases so treated should be 3200—the natural death-rate—plus the number of cases caused by the treatment, ever so many more than 3200. But the total deaths have been only 283. Contrasted with the fatality of the other diseases, diphtheria, typhoid fever, &c., the death-rate is very low. With these facts before him, every medical man is bound in duty and in conscience to recommend or, at least, offer the Pasteur treatment to every patient bitten by a dog presumably rabid. The medical profession are not biased in favour of anti-rabic inoculations, but would, I believe, prefer a treatment by other means, if any could be discovered nearly as successful as the Pasteur inoculations. While hydrophobia is such a dreadful death, while so many of those bitten contract the disease if untreated, while Pasteurism diminishes the cases and the deaths at least 18 per cent., and while there is no other efficient treatment before them, so long will the public demand the application of the anti-rabic inoculation to the bitten, and so long must the medical profession advise their patients to resort to it.

I am, Sirs, yours faithfully,
Twickenham, Dec. 18th, 1895. H. HOWARD MURPHY.

*** We have compared Dr. Murphy's figures with those given in the "Annales de l'Institut Pasteur" and find them calculated correctly. The 283 deaths are those given by the anti-vivisectionists. M. Pasteur used not to count deaths occurring within fifteen days of the first inoculation, so that the deaths for 1886–94 work out at 81. We would refer the opponents of the practice to consult the report of the Royal Commission appointed in 1886, an abstract of which appears in our columns of July 2nd, 1887, signed by such weighty names as those of Sir James Paget, Sir Richard Quain, Dr. Lauder Brunton, and others.—ED. L.

"TREATMENT OF SMALL-POX BY EXCLUSION OF THE CHEMICAL RAYS OF DAYLIGHT."

To the Editors of THE LANCET.

SIRS,—In your annotation under the above heading in the current issue of THE LANCET you mention the communications you have received from Dr. Moir, Dr. Finsen, and Dr. Feilberg; allow me to remind you that in 1871 (Feb. 4th and April 22nd) you published two articles on this subject by me, in which my experiments on plants and animals were described, and the reasons given on which I based my treatment of small-pox. Not to recapitulate, I may say I found, first, disease modifies the sensibility in the skin—i.e., sensation may be altered and perverted by it, due to some change produced in the nervous system not well understood; secondly, diseases that are partially eliminated by the skin increase its susceptibility to stimulation, so that what in health would be beneficial to it is by disease rendered hurtful; thirdly, light under ordinary circumstances—i.e., in health—is a desirable stimulant, but has detrimental effects in small-pox, scarlet fever, measles, &c.; fourthly, by excluding the white rays of light from patients suffering from these diseases, I find that in practice most beneficial results follow. These were the conclusions I came to twenty-four years ago, and I can say they have been confirmed in most, if not all of, the cases that have been under my care since then.

I am, Sirs, yours faithfully,
Jermyn-street, S.W. J. H. WATERS, M.D. Glasg.

"'TUBERCULOUS' *VEL* 'TUBERCULAR?'"

To the Editors of THE LANCET.

SIRS,—Kindly allow me to question the correctness of the judgment concerning "tuberculous" and "tubercular" in THE LANCET of Dec. 7th. What is the proper use of each of these words? The termination "ous" means "full of" or "abounding in"; the termination "ar" means pertaining to. In some words with both terminations the distinction is well preserved, as, for example, in "populous" and "popular." In others the distinction is nearly obliterated; but in so far as retained is to the same effect, as, for example, in "granulous" and "granular," "tubulous" and "tubular," "nodulous" and "nodular." Reference to a good dictionary, like Webster's, will settle this point. The tendency, however, is for the termination "ar" to supplant its rival. If indiscriminately used, the termination "ous," with its definite meaning, would often be wrong, while the less definite "ar" would nearly always be right. A concrete noun with the termination "ar" becomes an abstract adjective, meaning "having the qualities" belonging to the things signified by the noun; but with the termination "ous" the concrete force is retained, the meaning being "full of the

Digitized by Google

things" indicated. We may quite properly speak of "tuberculous meninges"; but to speak of "tuberculous meningitis or osteitis" is almost as bad as to speak of a "populous fallacy." A writer unable to discriminate between the two terms will therefore do wisely to adopt "tubercular" to the exclusion of "tuberculous." As to usage, on looking through the books at my disposal I find a great preponderance of authority in favour of "tubercular meningitis." The appeal to French and German usage can hardly be allowed much weight. We must surely be guided by the genius of our own language. I am, Sirs, your obedient servant,

WILLIAM R. HUGGARD.

Davos Platz, Switzerland, Dec. 10th, 1895.

THE METROPOLITAN ASYLUMS BOARD AND THE CHAIRMAN OF THE POPLAR HOSPITAL.

To the Editors of THE LANCET.

SIRS,—You write in a leading article in THE LANCET of Dec. 14th that "it is a little disappointing to see a man of Mr. Holland's position as chairman of a hospital say in a letter to the *St. James's Gazette* that the Metropolitan Asylums Board ought to provide for every scarlet fever case in London." If my opinion is of the slightest interest, will you kindly allow me to say that my mode of communication with the *St. James's Gazette* was a hurried interview, at their request, and not by letter, and that though my words certainly bear the construction you put on them I never meant to imply that the Metropolitan Asylums Board should do more than *take cases from homes where proper isolation is impossible*, and not all cases occurring in London? This limited duty, however, would cost them the million I mentioned. My special complaint against the Metropolitan Asylums Board is that I believe they had room for our Poplar Hospital patients, though not perhaps at Homerton, and considering how very serious it was for these patients, who were injured by accidents as well as infected with fever, to be sent to homes where neither injuries nor fever could be attended to, I do think that the officials of the Board might have done much more than they did for us. Further, after the officials had refused to take the patients we applied at Norfolk House for an ambulance to remove them to their homes. There we met with a blank refusal unless our medical officer would guarantee that they could be properly isolated at those homes. This he of course refused to do. He could, of course, guarantee nothing of the sort, nor do I believe that the officials were within their legal rights in refusing the ambulance to us on such grounds. You defend the Board; but surely it is to be regretted, to put it as mildly as possible, that they should have taken this moment for giving notice to all the staff at and closing Gore Farm with its 700 beds. This does strike a layman as curious conduct, when just now is the worst fever time, and when an epidemic of scarlet fever was in existence which admittedly the Board was unable to cope with. I know that the hospital there is an exposed one, and I know that the medical authorities condemn it for that reason, which, by-the-bye, says very little for the judgment of the Board in erecting a hospital there at all. But surely any hospital, in however exposed and cold a site, gives a better chance of recovery to children than a crowded home in a crowded district, and their removal there is certainly better for the community at large.

I am, Sirs, yours faithfully,

SYDNEY HOLLAND,
Chairman of the Poplar Hospital.

Dec. 14th, 1895.

THE SLAUGHTER OF CATTLE AND MEAT INSPECTION AND DISTRIBUTION.

To the Editors of THE LANCET.

SIRS,—If, as was laid down by the deputation to the President of the Board of Agriculture, it is desirable to formulate fresh regulations for the slaughter of foreign cattle at the ports of debarkation for the protection from disease of our flocks and herds, it is even more desirable to introduce amended legislation for the protection of human beings from the perils to which they are exposed by the consumption of meat which has not been certified by competent authority to be fit for food. At present, animals brought to the market or auction sales are transported, sometimes with the infliction of much pain and hardship, to the great centres of population, and are then driven, for the most part, to private slaughter-houses, often situated in the poorest and most populous districts, where the due inspection of the animals before killing, and of the meat afterwards, is surrounded with considerable difficulty. Is it not possible for the killing to be done in public slaughter-houses near main railway stations, contiguous also to the farms where the animals have been reared, the meat being then carried, if the railway authorities coöperate, by special meat trains fitted with the necessary refrigerating chambers? The general adoption of such a method throughout the land would be for the benefit of all concerned; the pain accruing to the animals would be reduced to a minimum, the long journeys in trucks and along narrow streets would be things of the past, and the slaughtering would be performed in the humanest possible manner by licensed slaughterers. Cattle markets, auction sales, and slaughter-houses might, by such coöperation as that suggested by the Duke of Devonshire in his letter to the Agricultural Union, be under the control of the breeders of cattle themselves, to the pecuniary gain of the farmer, and thus to the substantial advantage of the agricultural interest generally: not only would the animals be inspected before killing by properly qualified veterinary surgeons, but the meat would undergo a rigid scrutiny before being despatched to the market; butchers and their assistants, who deserve well of their countrymen for their valuable services, would be relieved in a measure of grave responsibilities; a continuous supply of good, sound, wholesale meat would be the boon secured for our teeming populations; and the standard of public health would be materially raised.

To further such a reform as is here proposed the Church Society for the Promotion of Kindness to Animals and the Church Sanitary Association are engaged in promoting a memorial, already influentially and numerously signed, and the President of the Board of Agriculture has consented to receive this memorial at the hands of a strong and representative deputation headed by the Duke of Westminster. The Lord Mayor of York and the Mayors of Leeds and Durham have shown their sympathy by granting the use of their parlours for conferences to be held in those cities. The names of those who desire to take part in the deputation or to sign the memorial will be gladly received.

I am, Sirs, your obedient servant,

F. LAWRENCE, Hon. Sec.

Westow Vicarage, York, Dec. 16th, 1895.

STATISTICS OF HOSPITAL TREATMENT.

To the Editors of THE LANCET.

SIRS,—All hospital physicians and surgeons are aware of the difficulties of keeping in touch with patients when they have been discharged from the wards after surgical or other treatment. It often occurs that a patient presents himself at the out-patient department for some affection which is the sequel of some operation performed at another hospital, perhaps some years previously. The patient does not remember the date of the operation or of his admission, and although the surgeon communicates with the registrar of that hospital he is in many cases unable to find particulars of the cases. In order to cope with this difficulty to some extent I would suggest that when a patient is discharged he should be given a card—blue for medical, red for surgical cases—with his name, number in hospital register, dates of admission and discharge, and name or number of ward, with a request printed thereon to the effect that he should present the card if he again applies for relief at the same or at any other hospital. Such a card (if it were kept by the patient) would at any rate give the surgeon particulars and enable him to communicate with the registrar of the hospital where the patient had been and so to obtain particulars. Such a card might well be given out by the ward sister, who might also tell the patient that it would be to his own advantage to keep it. If only some such plan could be generally adopted I think the notes of cases in some hospitals would be kept better than at present, and so be of value in making out statistics of certain modes of treatment. I need only to mention the radical cure of hernia as an example. It is, I am well aware, only occasionally that we meet with a case of exceptional interest from another hospital,

Digitized by Google

and generally only when the patient has changed his abode and has gone to live in another district; but in my own experience it is just in those cases that we are unable to obtain satisfactory details of the past history of the case.

I should be very glad to hear if any such plan as the one proposed exists in any hospital, and to receive any suggestions with regard to it.—I am, Sirs, yours faithfully,

Grosvenor-street, W. PEYTON J. B. BEALE, F.R.C.S.

*** Mr. Peyton Beale's letter deals with a subject of considerable importance to those engaged in hospital work and so, secondarily, to the whole profession. We hope that his letter may be fruitful in bringing forth suggestions.—ED. L.

A REMARKABLE SERIES OF INFANTILE MALFORMATIONS.

To the Editors of THE LANCET.

SIRS,—The following series of congenital and accidental malformations is probably unique and seems worthy of a corner in the pages of THE LANCET. My wife's ayah tells me that her sister, a Malay, perfect in form, has given birth to seven children within the last ten years, and that all have died. Upon interrogating her, I got a report as follows. The first child, born with a deformed left pinna, lived six months. From the description this would seem to be a case of absence of the cartilage of the external ear. The second child presented a double harelip and cleft palate, and lived two months. The third child was found to be minus the left forefinger and only lived three months. The fourth child lived three days and wanted the left great toe. The fifth child showed no external deformity, but lived three months only. The sixth child presented what seems to have been a dermoid cyst of the neck. The seventh child had just died, three days after birth, and presented a large tumour on the occiput, apparently a hydrencephalocele. I regret that I have not seen the woman or any of her children, but from inquiries of her sister it seems that both the woman and her husband present no congenital deformities, and none of the infants bore any traces such as might be attributed to congenital syphilis. I am, Sirs, yours faithfully,

Singapore. H. CAMPBELL HIGHET, M.D. Glasg.

"THE BATTLE OF THE CLUBS."

To the Editors of THE LANCET.

SIRS,—I have perused with much interest the article in your issue of the 14th inst. on the working of the Royal Victoria Dispensary, Northampton. On the whole I cannot complain of its tone; it puts both sides of the question fairly enough, but your correspondent has, inadvertently I am sure, done a great injustice to one of our medical staff. He refers to a prominent medical man who has received as much as £1000 a year from the dispensary, and suggests that he does no part of the work. I can vouch from my own personal knowledge that the gentleman in question did for a number of years a very large share of the work, and still takes an active part both in seeing patients and supervising the work of his assistants, and that the lively personal interest he has taken in the institution has conduced very greatly to its success during the years he has been connected with it. I might say more about the reasons that have made him so popular, but as he will probably read this I refrain from doing so. I am, Sirs, faithfully yours,

L. L. BECKE,
Honorary Secretary, Royal Victoria Dispensary, Northampton.

Northampton, Dec. 17th, 1895.

A PROMPT REPUDIATION.

To the Editors of THE LANCET.

SIRS,—I deeply regret that the zeal of an indiscreet friend should have placed me in the unsavoury position indicated by a paragraph in your current issue, and will take care that no such incident shall again occur so far as I can prevent it. Until I read your remarks I had never even heard of the publication you criticise. While admitting the justice of your animadversion you will, perhaps, however, permit me to express a hope that the heading of the paragraph in question is intended to apply to the manner and not to the matter of the part concerning myself. The words quoted denote a position in reference to treatment which I have openly taken up for years past, and from which I see no reason for receding.—I am, Sirs, yours faithfully,

HERBERT SNOW.

Gloucester-place, W., Dec. 15th, 1895.

*** We had no intention of suggesting that Dr. Snow's particular views were "rubbish" when we placed that word over our annotation in last week's issue (*vide* p. 1520). The word expressed our mental estimation of the whole of the letter as gravely intended for the general press.—ED. L.

NYSTAGMUS OF UNKNOWN CAUSATION.

To the Editors of THE LANCET.

SIRS,—The pathology of nystagmus is sometimes most obscure. I have under my observation a case which appears to me to be even more difficult to account for, if that is possible, than the case recorded by Mr. Dunlop Owen. A domestic servant aged twenty-eight consulted me first on Jan. 16th, 1893, and has been seen by me, off and on, up to the present time. In December, 1892, the movements of the eyes were first noticed. When I saw her in January, 1893, vision was ⅔ with each eye, not improved by glasses. Both fundi were normal. In each eye there was combined lateral and rotatory nystagmus. She complained that when anyone was coming near her she took some time before she properly recognised who it was. She also said that she occasionally felt a little "giddy." These two symptoms came on when she first noticed the oscillation of the eyeball. The knee-jerks were normal. She has two sisters and one brother, all without nystagmus. On Dec. 16th, 1893, I noted that "the giddiness is not now present, the general health is good. She cannot say that objects move when she looks at them, but she takes time before she sees well." On Nov. 7th, 1895, with the exception of the nystagmus and slight anæmia, I found nothing wrong with her. Since this visit the anæmia has improved. In this case we can, I think, eliminate albinism, errors of refraction, diseases of the media and fundi of the eyes, insular sclerosis, lead poisoning, hysteria, locomotor ataxy, and intracranial tumour. I am, Sirs, yours faithfully,

Londonderry, Dec. 16th, 1895. E. DONALDSON.

"SHOULDER BRACES."

To the Editors of THE LANCET.

SIRS,—I agree with Mr. Bernard Roth's letter on this subject to the extent that a rigid brace simply splinting back the shoulders might have the effect he deprecates, but I doubt if such braces are ever now used. On the other hand, it is my experience as a principle that spring force, whether exerted by metal or elastic, helps atonic muscles (be they spinal, scapular, or others) to act within the range of effort that they can undertake without fatigue, and leads to their development and not to their deterioration. But Mr. Roth is so entirely imbued with the gymnastic treatment to the exclusion of all others that he pronounces what "for many years I have taught" as being quite *ex cathedrâ*, and asperses the carefulness of your editorship by believing that "you have given, most probably inadvertently, a paragraph" to treatment of another kind than his own. Nay, more, to substantiate his tenets he quotes an extract from the work of the late Mr. John Shaw. If Mr. Roth looks at p. 141 of the very work to which he appeals he will find the following enunciation: "But although the most beneficial effects are produced by exercises, we shall be disappointed if we trust entirely to them in cases where the spine is actually distorted, or even when the curvature is slight. I am often told of extraordinary cures effected merely by exercises, but I have not been able to see any such instances." This being so, it would be ungracious to disagree from the deserved encomiums Mr. Roth passes on Mr. John Shaw when he says that he was "one of the most clear-headed writers on orthopædic surgery that I have come across," and when he concludes his letter with this satisfied termination: "I do not think any impartial surgeon would controvert John Shaw's sensible remarks written seventy years ago."

I am, Sirs, yours faithfully,

Wimpole-street, Dec. 13th, 1895. HEATHER BIGG.

Digitized by Google

"DANGERS AT SCHOOL."

To the Editors of THE LANCET.

SIRS,—My attention has been directed to a reference in an evening newspaper alluding to a paragraph entitled "Dangers at School," indicating a probable means of transmission of diphtheria and tuberculosis among school children by means of infected slates. I beg to say that I made this conjecture and reported to this effect to our sanitary authority while investigating an outbreak of diphtheria, having arrived at this conclusion by reason of certain facts which came under my observation during these inquiries, and after watching children frequently moisten their slates with saliva and then pass them on to their companions or place them among other slates to be used by their fellow-pupils at some future time. Thus, given an unrecognised case of diphtheria, recrudescent, or an infected throat, herein appears to lay the explanation of a frequent means of transmission of these diseases. I stated this publicly and superintended and advised boiling the slates in a solution of sodium carbonate.

I am, Sirs, yours faithfully,

Maidstone, Dec. 11th, 1895. PERCY T. ADAMS.

"HOSPITAL ABUSE AT BRIGHTON."

To the Editors of THE LANCET.

SIRS,—I hope you will find space in the columns of THE LANCET for a few remarks I have to offer on the above subject. Having read carefully the letter in one of your former issues sent to the dispensary committees, and signed by some of the oldest practitioners in Brighton, there are a few facts that I would like to draw their attention to, of which, perhaps, they are not aware. Why are dispensary letters given to tradespeople and those in comfortable circumstances? Simply this: because the young medical men holding appointments in those institutions, who are in a better position than the dispensary committees to judge of the circumstances of patients applying for letters, hope at some future date to set up in private practice in the district. This, of course, they consider as a good introduction, and will raise no objection to visit well-to-do patients. I would be inclined to doubt this statement if it did not come from a reliable source. But what are you to do when one of those gentlemen themselves volunteers the information? If such an unprofessional spirit prevails amongst the gentlemen holding these appointments, I see no way out of the evil, except that they should not be allowed to practise in the district afterwards.

I am, Sirs, yours faithfully,

Brighton, Dec. 16th, 1895. ONE INTERESTED.

"THE ADMISSION OF WOMEN TO THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—In reply to the letter of the secretary of the Clapham Maternity, regarding the lowering of fees by female medical practitioners and consequent degradation, I wish to point out that when this institution was started as a private speculation by Dr. Annie McCall the whole of the neighbouring district was flooded with touting circulars placed in the letter-boxes of other practitioners' patients, where, amongst other items of charges, confinements were undertaken at 5*s.* a head. This circularising of the whole district was repeated at regular intervals. The institution has since developed into one "supported by voluntary contributions." What was once a private speculation has become a maternity hospital, kept up for the benefit of two or three female practitioners and the students who have to get their cases. Many also state that the present secretary—the lady who signed the letter in your last issue—is well aware of the above facts. Will she deny that the above is a true statement?

I am, Sirs, yours truly,

Dec. 16th, 1895. VIGILANS.

THE council of the Medical Guild, having discussed, clause by clause, the Draft Midwifery Nurses Bill as proposed by the Lancashire and Cheshire Branch of the British Medical Association, unanimously passed the following resolution: "That this council express their dissatisfaction with the Draft Bill as it stands and their determination to oppose it."

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Death Sentence: a Warning.

THE recent trial of the woman Eden at the Warwick Assizes revealed some painful facts. It seems that she brought on an abortion which terminated fatally, for which she was convicted of murder and sentenced to death. Another death is also attributable to her treatment—that of a barmaid from Leeds. The judge remarked that it was quite clear that this woman had been practising a wicked trade which had become far too common in this country. He spoke in laudatory terms of the medical profession in connexion with the case. The public are hardly aware of the risks run by the ignorance and recklessness of such a woman, and are wont to somewhat condone such nefarious practices when carried out at the request of the sufferer herself. The law is decisive upon the matter; it is well for society that it is so. It cannot be too well known that the practice of procuring abortion is morally wrong, personally dangerous, and legally criminal. In this instance relief is experienced by the reprieve of the condemned woman by the Home Secretary. Repugnant as such a vice is, and hideous the picture of a woman being hanged, protection must be afforded to society in the aggregate; the warning is therefore salutary and well timed.

Children and Firearms.

A shocking accident ending in the death of a child aged eleven by her brother's act lately occurred here. The brother, aged nine years, opened a drawer in his father's bedroom and found a five-chambered revolver fully loaded. Taking this out he pointed it at his sister and pulled the trigger; the little girl received the bullet in her head and fell dead instantly. The distress of the parents was great. The father stated that he bought the revolver owing to a scare of burglars; placing it in a secret drawer, he considered it safe. The fear of burglars is a lesser one than the danger of a loaded firearm in a house where it is possible for children to get access to it. This is a melancholy illustration of the fact. To place such weapons under lock and key is an obvious deduction from the risk of such terrible accidents.

Prosecutions for Drug Adulterations.

Some important and interesting prosecutions took place at the police-court recently. Four retail chemists and druggists were summoned for selling articles which were not of the nature, quality, and substance demanded. In two of the cases tincture of iodine, and in the other two tincture of aloes, had been sold which were in excess of the strength prescribed in the British Pharmacopœia. The medical officer of health and public analyst stated that one sample contained 40 per cent. more ingredients in solution than the Pharmacopœia ordered, while, at the same time, the spirit was much stronger than it should have been. The principle is of great importance, for in buying a drug it is necessary that it should be of known quality. Fines of £1 and costs were imposed notwithstanding the ingenious defences set up.

Queen's College.

After two unsuccessful attempts to hold an annual meeting of the governors of this college a quorum was made up on the 12th inst. The severance of the medical faculty has evidently left the college in straitened circumstances. Sir Walter Foster stated that the supply of theological students from the universities was not enough, and that it was necessary to fall back upon such colleges as these. He hoped always to be connected with it, and expressed his regret at anything approaching the decline of such organisations. He advocated amalgamation with similar colleges as a relief to the present difficulties. Dr. Wade resigned his position as governor, writing that he was interested in medicine and not in theological teaching. Altogether the college is in a very poor way, and threatens to die from inanition if some vigorous efforts are not made for its recovery.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Unqualified Practitioners.

TWO cases were heard at the county-court on the 9th inst., when local quacks received a slight check. In the first the plaintiff sought to obtain the return of 21 guineas and

Digitized by Google

damages from "a hernia specialist" named Sherman, for alleged negligence and fraud. He went to Sherman and signed a paper specifying what he required, and what he was suffering from, then submitted to a "preliminary examination," and paid a guinea. He was told he had a rupture on the right side, and could be cured for £20. He paid the money after the defendant assured him he could cure him, and received a receipt and agreement, which, however, gave no guarantee as to the cure; but Sherman gave his word "as a gentleman" that he could and would cure the rupture. "The plaintiff accepted the statement, and thereupon the defendant fastened an appliance upon him and gave him a bottle of his curative compound." After enduring much pain, and being several times assured that he was "getting cured," he saw Mr. Whitestone of Middleton Junction, who told him he had a slight rupture on the right side only and advised him to wear a truss, and said the pain was due to "the appliance." After all this he saw Sherman again, who then said he had a rupture on the left side and promised to cure him for ten guineas, but this time he gave up the "appliance" and Mr. Sherman as well. Mr. Whitestone, Mr. Walter Whitehead, senior surgeon to the Manchester Infirmary, and Mr. Robert Collier stated in evidence that the appliance—as it was always called—was an improper one. The defendant stated that "he had been carrying on his present business nearly four years, and before that was with his father, who had a similar business in London, and that "prior to engaging in his present business he was connected with horse-trotting in the United States." According to the newspaper report, "Dr. John Tanner of London, who held a number of high qualifications, said he had examined the appliance referred to, and thought very highly of it. In his opinion he had never seen anything better." His Honour Judge Parry said the case was important to the public, "because one could not but know, looking at the newspapers daily, of the large number of unqualified medical practitioners who were paid large fees. ..... The question was, Did the defendant tell lies to induce the plaintiff to pay £21 for an article which might perhaps be worth 10*s.* 6*d.*?" He held that there had been fraudulent representation, and gave judgment against the defendant for £22 and costs; so that the issue turned, not on irregular or unqualified practice, but on fraudulent trading. The second case was an action against Robert Whitehead, a "cancer specialist" of Manchester, for £15 damages. The plaintiff, a cook, saw the defendant early in the year and was told she was suffering from weakness. Two months later she noticed a growth on the chest, which he said was a tumour, adding that it would turn into a cancer. He gave her some plaster and medicine and "painted the place with something which gave great pain." Her mistress sent her to Mr. Walter Whitehead, who removed the growth. In his evidence he said the growth was not a cancer and the treatment had been barbarous and cruel. Mr. Alexander Wilson of Manchester gave similar evidence. The defendant said he had applied his treatment with "profound success." "In all other cases he had treated for a similar purpose he had never known inflammation to follow." These cases always prove the rule by being the exceptions. The judge said "the defendant held himself up as being able to cure cancer." He appeared to have told the plaintiff that her complaint might become a cancer, and applied his specific with harmful results. "As long as people would pay for unqualified assistance they must be allowed to do so. In this case definite harm had been done, and the woman had to go to a hospital to undergo an operation by a man of real and high qualification." She was awarded £10 and costs. Here, again, the unqualified practice goes for nothing, and the verdict is for the injury done to the plaintiff. Quacks have many advantages in this happy land.

A "Miracle" at Stockport.

There has been some excitement at Stockport over the following case. The wife of a mill hand, now forty-eight years of age, is said to have taken to her bed sixteen years ago, and to have been unable to walk till about a month since, in spite of medical assistance of all kinds. She is stated to have been an in-patient of the Stockport Infirmary seven times. On the day the "miracle" occurred she seems, according to the account given, to have had a strong mental impression, as she says she distinctly heard a voice say: "Arise, my child, thou shalt walk again"—a somewhat comical way of addressing this woman of forty-eight. Thereupon "she got out of bed and walked across the floor, saying 'Lord help me!' Since that time she has had no difficulty in walking." It seems hard on the husband that she waited so long before hearing the voice, and a pity that it cannot be claimed as a cure by a hypnotic "suggestor." Perhaps, however, one "suggested" at a distance.

Habitual Drunkenness.

A woman only twenty-five years of age was brought the other day before the Burnley magistrates for the fifty-eight time for drunkenness, having been found drunk two hours after leaving the court on the previous Wednesday, where she had been fined for the third time within a week. "She had been in a girls' home and given up as hopeless, and the police, it was stated, frequently overlooked offences, as they were tired of locking her up." She must be well known to the local publicans, who, to their disgrace, supply her with drink, and who deserve punishment quite as much as she does. She has probably no wish to restrain her craving for drink, and no power if she had the wish. Surely this is a case where she should be protected from herself and detained in a suitable asylum, both for her own sake and for the safeguarding of society against the risk of her presenting it with a family of hereditary drunkards.

Life-Saving Round Manchester.

The Humane Society for the Hundred of Salford makes a presentation of medals at its annual meeting, which was held the other week in the Town Hall, the Lord Mayor being in the chair. The saving of thirty lives during the year, the greater number from drowning, was acknowledged by various rewards. Eighteen silver medals, one silver bar, and eleven money rewards were given. A man named Unwin, employed on the Rochdale Canal, has saved many lives from drowning, and has already received the gold medal of the Society, with two gold bars, a silver medal with two silver bars, and on this occasion another silver bar was added to the ribbon of the medal to commemorate his saving a boy this year from drowning. Besides these medals, twenty-one silver badges were given to boys and girls from some of the schools of the city, who in competitions had shown themselves sufficiently "proficient in swimming exercises to be enabled to save life." A "dummy figure," on which life-saving can be practised, has been provided at each of the public baths and found very useful in teaching. The public swimming-baths are popular, and the teaching of the best modes of seizing a drowning person in the safest and most efficient manner is worthy of every encouragement.

National Society for the Prevention of Cruelty to Children.

A grand bazaar, extending over several days, in aid of this society, has been held here, and closed on Saturday last. It has been supported by Lancashire chiefly, but parts of North Staffordshire, Westmorland, and Cheshire have joined in the work. The receipts have amounted to £10,300, and a subscription has been organised to defray the expenses, so that the total received may go to the society. The receipts will be increased somewhat, as the unsold goods were yesterday disposed of by auction. The special object of the bazaar was to aid in the establishment of a reserve fund of £40,000, towards which about £25,000 have now been obtained by similar efforts in various parts of the country. When one thinks of the almost daily records of gross and often fiendish cruelty to children, it seems as if the society should be approved by all humane people; but, from a letter in this morning's *Courier* from a "victim," who, however, has the courage to sign his name, it does not appear to be so, and he quotes from Mr. Justice Grantham's charge to the grand jury at the York assizes. As reported in the *Manchester Weekly Times*, he referred to this society and said "it was very dangerous that the society should interfere with prosecutions," and that it was desirable that these prosecutions should be in the hands of the police, who represented the Crown, and whose duty it was not to get convictions, but to further the administration of justice, whereas this society appealed for support on the ground of what they did, and quoted the number of convictions. He adds that "it would be a sad day indeed if the police should become so negligent of their duty that their duties should be taken up by a society, and the police relieved of their responsibility." The existence of such a society in no sense can be taken as doing away with police responsibility. Many causes may interfere with the efficiency of police supervision, and it may be asked, How many of these convictions (which we may safely assume to be just, as the law is administered by Mr. Justice Grantham and his colleagues) would have occurred if it had

Digitized by Google

not been for this society? Its formation was due to this very inefficiency of the police to prevent cruelty to children, and the law as administered may be trusted to check any prejudiced or malicious prosecutions, if we may suppose them to be attempted.

Dec. 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Professor Annandale's Health.

SOME weeks ago Professor Annandale had so far recovered that he was able to resume the duties of his chair in so far as to deliver the regulation lectures. This he has continued to do, but it has been thought advisable that he should go for a trip to the Cape. He will sail early next year and will be absent for about four months. Many of his old students in South Africa will be pleased to meet their old teacher.

Leith and Edinburgh.

The question of the proposed temporary hospital which Edinburgh desires to erect within the Leith boundary has been adversely pronounced upon by the Leith Dean of Guild Court. The question will probably go to a higher court.

The Royal Infirmary Kitchen Concert.

The time-honoured Kitchen Concert was held last night in the Edinburgh Royal Infirmary, and passed off with the customary *éclat*.

The Christmas Vacation.

The Christmas vacation will begin in Edinburgh on Monday next and last for a fortnight.

The Edinburgh Medico-Chirurgical Society.

This society will hold a special meeting to-morrow (Wednesday) afternoon for the exhibition of patients and specimens. The society only occasionally has these clinical meetings, but many members think they are very useful and could with advantage be held more frequently. The time of meeting is also of the nature of an experiment.

Benefactions to Glasgow Infirmaries.

The trustees of the Bellahouston fund have made the following additional bequests: 1. To the Royal Infirmary (1) a grant of £2500 in supplement of an equal sum already paid by the trustees for the better equipment of the medical school; and (2) a grant of £7500 towards the erection of a pathological museum and laboratory and another operating theatre to be called the "Bellahouston theatre." 2. To the Western Infirmary (1) a grant of £3500 for the erection of another operating theatre, to be called the "Bellahouston theatre"; and (2) a grant of £5000 towards the erection of pathological buildings. 3. To the Victoria Infirmary a grant of £6000 for the erection and equipment of a dispensary for out-patients, to be called the "Bellahouston dispensary."

Glasgow Maternity Hospital.

The following appointments have been made to the hospital staff:—Physician-accoucheur, Malcolm Black, M.D.; Assistant Physician-accoucheur, R. Jardine, M.D.; House-surgeon (in-door), A. A. Warden, M.B.; House-surgeon (out-door), A. Kay, M.B. Professor Murdoch Cameron has retired from the acting staff, his term of office having expired.

Scottish Poor-law Medical Officers' Association.

An association having for its main object the promotion of the interests of medical officers appointed under the various local authorities has recently been formed. The first meeting was held in Glasgow on the 9th inst., when office-bearers for the current year were appointed.

The Victoria Infirmary, Glasgow.

The eighth annual report of this infirmary shows that the accommodation provided by the new wing recently erected has been fully utilised, every bed during the past year being nearly continuously occupied. The average cost of each fully-occupied bed has been £62 3*s*. 5*d*., and the average cost per patient £5 16*s*. The directors thankfully acknowledge a donation of 1000 gs. from Mr. Cameron Corbett, M.P., towards the expenses of the out-door dispensary, as also the sum of £6000 from the Bellahouston Trustees.

Aberdeen Medico-Chirurgical Society.

The annual dinner of the Medico-Chirurgical Society of Aberdeen was held on Saturday evening in the Medico-Chirurgical Hall, King-street. Professor Stephenson occupied the chair. Dr. Ogilvie Will acted as "croupier." The chairman submitted the loyal and patriotic toasts, which were duly honoured. A very large number of members and guests were present, and the speeches were bright and good.

Dec. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Mr. William Dudley White.

ALTHOUGH not connected with any of our clinical hospitals, Mr. Dudley White was very widely known and esteemed by the medical profession in Dublin. He held for many years one of the dispensaries of the North Dublin Union and was visiting physician to St. Mary's Industrial Schools and to the Hospice for the Dying at Harold's Cross. His father was a prominent citizen of Dublin, where he filled the position of coroner; while his son, Mr. J. Dudley White, is at present a distinguished undergraduate and scholar of Trinity College. The deceased gentleman's funeral was very largely attended. At the general meeting of the Dublin University Philosophical Society on Thursday last the following resolution was carried unanimously: "That the Society expresses its deep sympathy with Mrs. White and with Mr. Dudley J. White (Sch.), honorary registrar of the Society, in their great bereavement, and that the Society do now adjourn as a mark of respect and sympathy." The motion was proposed by Mr. R. J. Rowlett (Sen. Mod.), honorary secretary, and seconded by Mr. R. T. Harris, M.A. The society then adjourned without transacting any business.

Dublin Orthopædic Hospital.

The annual meeting of the friends and subscribers to this hospital was held on the 12th inst. in the board-room of the institution. Mr. Swan read the report, which was of a highly satisfactory character.

Infectious Diseases in Dairy Premises.

The guardians in Belfast, having written to the Local Government Board requesting them to name the infectious diseases the existence of which in dairy premises would justify the guardians in having the dairy closed, have received a reply that the medical officers of the Belfast union of guardians, from their professional attainments and experience, are well qualified to advise the guardians on the question, but that it appears to the Local Government Board that the existence on dairy premises of any of the following diseases would justify the guardians in taking action—viz., cholera, small-pox, typhus fever, enteric (typhoid) fever, puerperal fever, scarlet fever, and diphtheria. The question of measles being included is left to the guardians' medical officers. The value of this communication lies in the circumstance that it specifies the names of the diseases for the existence of which a dairy may be closed, because, as a guardian present (Dr. Gibson) at the last meeting stated, some time ago there was a difficulty in securing a conviction in a case where typhoid fever existed in a dairy owing to the medical officer hesitating to say whether typhoid fever was infectious, as distinguished from contagious, the regulations formerly only applying to such cases as, in the opinion of the medical officer, were contagious.

Belfast District Asylum.

Dr. O'Farrell, inspector of lunatics, in his memorandum of inspection of the above asylum on Nov. 1st, which has just been published, states that he believes no public institution in the United Kingdom is at present more overcrowded than this asylum; yet he found every department orderly and clean, while its bill of health is favourable and its mortality-rate very low. With such perilous surroundings, with dormitories so full that there is scarcely space for beds, he thinks the resident medical superintendent deserves the greatest credit for his good and careful management of the institution. It is a curious thing that with so much zymotic disease prevailing in Belfast, there have been no cases in the asylum.

"The Rate of Speed for Ambulances."

I understand that the Police Committee of the Belfast City Corporation have, in deference to the verdicts of the

Digitized by Google

coroner's juries,[1] decided to allow the ambulance carriages, when summoned to an accident, to go at a rapid pace, and not, as complained of, merely at a trot as formerly.

Typhus Fever in Ireland.

I regret to say that the hopes of modern sanitary authorities, that this disease—which in Ireland has so often claimed as its victims members of the medical profession—would soon become eradicated, are being so very slowly realised. I have reported in this column accounts of outbreaks at Ardboe (in the vicinity of Lough Neagh), from which the patients were removed mainly to Cookstown Workhouse, and also at Ballyclare, where there has been a very serious epidemic. I am sorry to say the disease has broken out in Killybearn, in the Magherafelt Union. So far in Belfast at present typhus fever is not prevalent, but if introduced its spread would not be diminished owing to the want and poverty which are following in the wake of the present most unfortunate strike of the ship-building engineers. A rather serious outbreak has also been reported from a town called Shillelagh in the county of Wicklow. Twenty-four cases of epidemic typhus fever are now being treated in the workhouse hospital there.

Belfast Naturalists' Field Club.

Dr. Lorrain Smith, Lecturer on Pathology at Queen's College, Belfast, gave, on Dec. 13th, a very interesting lecture on the Study of Bacteriology before the microscopic section of the Belfast Naturalists' Field Club.

Pollution of the Water-supply of Cork.

Mr. Donovan, superintendent medical officer of health of Cork, has made a most important report relative to the water-supply of the city. He stated it had come to his knowledge that the sweepings of the streets and the filth from the back-yards of Macroom were actually carted into the Lee as it passed that town. As the river so contaminated furnishes practically the sole water-supply to Cork, Mr. Donovan urged the extreme importance of impressing on the guardians of the Macroom Union the grave responsibility they incur, and he pointed out that as typhoid fever is somewhat more than usually prevalent in Cork at present, it is all the more requisite that possible sources of contagion should be avoided. The urban sanitary authority accordingly addressed a very strong remonstrance to the Macroom guardians, and should that prove unavailing I have reason to believe that the law will be invoked.

Who ought to Pay the Substitutes of Dispensary Medical Officers who have been Subpœnaed by the Crown?

This is a question which was proposed for the immediate solution of the Dispensary Committee of the city of Limerick. Two of the dispensary medical officers were ordered, under the usual pains and penalties, "all business whatsoever being put aside," to give evidence before the representative of Her Majesty at the winter assizes recently held in Cork. Accordingly, before proceeding to Cork the two medical gentlemen named for their committee two substitutes, and the latter took steps to convey to the committee that they could not put their services at the disposal of the guardians without a remuneration at the rate of three guineas a week. The secretary hastily convened a meeting, and the committee came to the conclusion that under the circumstances there was no course open to them but to agree to the proposed terms. Some of the newspapers grumble, and say it is very exacting on the part of the dispensary medical officers to expect to be paid salaries for the performance of duties which they cannot possibly discharge, owing to their absence in an adjoining county, whilst at the same time they are in receipt of handsome remuneration from the Crown. But the newspapers forget that the dispensary officers are allowed no option. They must give evidence which is beneficial to the ratepayers. For the "handsome remuneration" of three guineas a week they are obliged to neglect their private practice, which in many instances is their principal source of income, and a certain section of the public think they ought to be still further punished by the reduction of their salaries.

Lunatic Asylums in England, Ireland, and Scotland.

Mr. Kenny has procured a return relating to the number and treatment of pauper lunatics, which contains some interesting figures. From it I learn there is accommodation for 67,842 in England, 11,418 in Ireland, and 10,444 in Scotland. In England and Scotland the number of inmates did not nearly equal the number for which there was accommodation, but in Ireland it exceeded it by more than 1000. The annual cost of maintenance per head is £41 in England, £21 in Ireland, and £20 in Scotland. An interesting question for alienists to solve is why, as is shown by the return, female lunatics are in a majority in England and Scotland and male lunatics are in an enormous majority in Ireland.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Overcrowding at the Faculty of Medicine.

I HAD occasion to communicate to your readers in a recent letter the new rule which shuts the doors of the Paris Faculty on would-be students who, being foreigners, are not *bacheliers*. It is very evident that the authorities are alarmed at the ever-increasing number of entries, and, if I am correctly informed, at least one aspirant of British nationality has been refused a student's ticket, even though he had duly passed his *bachot*. In this case he was referred to the British Ambassador, the only consolation vouchsafed him being that the intervention of Lord Dufferin might possibly procure him the coveted admission. That matters are really serious at the Faculty from overcrowding is incontestable. The current number of the *Gazette des Hôpitaux* ("La Lancette Française") gives a prominent place to an alarmist article on the subject. The writer, who prints a graphic chart in support of his statements, very aptly asks what is to become of all the young men after graduation, seeing that even now most practitioners have much difficulty in making both ends meet. He accordingly calls upon the Faculty authorities to protect the aspirant against himself, and to stem a tide that can only end in disaster. It is, moreover, certain that such a glut of students must bring about a deficient standard of education, and that, therefore, both diligent and idle students must suffer from this plethora. For instance, last year 1348 names were on the dissecting list; now, to meet this demand, only 934 entire bodies and 589 bodies which had undergone post-mortem examination were received, and these had to serve in addition for competitions, examinations, laboratory, lecture, and research purposes, and for the classes of operative surgery. These left only 496 subjects for dissection distributed amongst 1348 students. The dissecting-rooms, large as they are, can only accommodate 720 workers; 200 more have, by a recent arrangement, been distributed amongst the various hospital amphitheatres. What become of the remaining 428? Clinical work is also, as may be imagined, heavily handicapped. Last year the number of *stagiaires* (ward work is compulsory on every student, who, if not an extern or intern, is called a *stagiaire*) was 1000; this year it will reach 1400. To meet this difficulty an auxiliary corps of clinical teachers has been organised, and, in addition, the Faculty has had recourse to the *bonne volonté* of volunteer professors, who cannot be paid owing to deficiency of funds. New regulations fix the duration of each student's *stage* in the wards at three years. This will give 2000 *stagiaires* who will have to be provided with instruction. The remedy suggested by the writer is to discourage entries and encourage the development of medical education at the provincial faculties and especially at the provincial preparatory medical schools. It is suggested, also, that the examination for the M.D. Paris should be rendered still more stiff, and if one may judge from the figures below there certainly would seem to be some scope in this direction. At the First Examination for the degree there is an average of 2·9 per cent. of candidates adjourned; at the Second Examination, first part 24·54 per cent. and second part 9·24 per cent.; at the Third Examination, first part 15·59 per cent. and second part, 17·39 per cent.; at the Fourth Examination, 16·03 per cent.; at the Fifth Examination, first part 10 per cent. and second part 8·56 per cent.; and for the Thesis, 0·55 per cent. As regards the admission of foreigners into the Faculty, it is suggested in the *Journal de Médecine de Paris* that, while the non-indigenous student be received with open arms, he should, after graduation, be denied the right to practise on French territory, his degree becoming thus a purely honorary title.

Recurrent Gonorrhœal Rheumatism.

Dr. Emery presented to the Société Française de Dermatologie et de Syphiligraphie (Dec. 12th) a man who had for the nineteenth time had gonorrhœal rheumatism and ten attacks of gonorrhœa. The first attack of gonorrhœa occurred in 1876; it was after the fourth (in 1878) that he had seven successive attacks of rheumatism, which left considerable deformity of the feet resembling that of chronic polyarthritis deformans, and a deformity of the middle finger which assumed the shape of a radish. M. Mauriac recalled in this connexion the history of a man who had during twenty-one years an annual attack of gonorrhœa accompanied with rheumatism. M. Fournier once had under his care a young man in whom each sexual act, even though means were taken to prevent infection, infallibly provoked an attack of rheumatism. So sure was he of this result that on these occasions he ordered his lunch to be served in bed on the morrow. Here there was no question of a fresh attack of gonorrhœa, the sexual orgasm sufficing to relight the joint pains. This would seem to support the medullary theory of the affection, and M. Gastou cited a case of blennorrhagic rheumatism where there was present disseminated muscular atrophy outside the articular area, which atrophy was considered by M. Oudin as being of medullary origin. M. Fournier remarked that directly he saw Dr. Emery's patient he diagnosed gonorrhœa from the radish-shape of the deformed fingers. A similar deformity exists in arthritis deformans, but in the latter disease all the digits are deformed, whereas in the gonorrhœal type, only one or two are involved.

Persistence of the Diphtheria Bacillus.

MM. Le Gendre and Pochon[1] have had under observation for the last fifteen months a child who, in less than three years, has had three attacks of diphtheria (once faucial, once buccal and nasal combined, and once nasal and faucial combined). Since the methodical bacteriological examination of the nasal and pharyngeal mucus has been undertaken (thirteen times since September, 1894), Löffler's bacillus has been invariably discovered, either retaining its virulent properties or deprived of them (not killing the guinea-pig), and either appearing in the form of average bacilli or being dwarfed, or again assuming the shape of the "coccus Brisou." Sometimes the bacillus was present alone and sometimes associated with the staphylococcus. Copious nasal and pharyngeal douches with a 5 per cent. solution of Labarraque's liquor caused the temporary disappearance, total or partial, of the bacillus. But a suspension of the treatment for some time is followed by a change in the child, who loses his gaiety, appetite, and colour; an examination then reveals the presence of the micro-organism. It is evident that it continued to lurk in the recesses of the nasal mucous glands. This example of latent microbism is worthy of record.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Battle of Amba-Alagi: the Red Cross.

THE reverse that has befallen the Italian arms in Abyssinia is but the prelude to the extension of hostilities, and already large reinforcements are on their way to the seat of war. As to the battle in which Major Toselli and his column of native troops were cut to pieces, it was so completely a surprise that much of what is interesting in such engagements is necessarily wanting. So far as advices to hand indicate, there was no medico-military service on any considerable scale, and beyond the fact that Dr. Jacopetti ("tenente medico") is among the slain, we know nothing as yet as to how far the medico-military arm was engaged. As to the Red Cross, there is no doubt that its resources and *personnel* will share in the general reinforcement now called for.

The Sale of Quinine.

Signor Boselli's Bill, by which the right to sell quinine of guaranteed purity will be conceded to those shops in town and country already privileged to sell salt, tobacco, and postage-stamps, has, not unexpectedly, evoked much criticism, favourable and unfavourable. I have already given what has been advanced in the former sense, and which may be summed up in the fact that the Bill is framed to meet exceptional circumstances and to make quinine obtainable in malaria-stricken localities where the chemist and druggist is unknown. On the other side, it is urged that this concession is an invasion of the pharmaceutical province; that the Government which exacts high qualifications from the dispenser of drugs has no right to "poach on his preserves" and compete with him in the sale of one of the most largely employed preparations in the pharmacopœia. The dignity of the apothecary's art, moreover, is compromised by raising the tobacconist to the rank of a vendor of quinine. Another objection which I have not seen urged is this: that quinine, unless medically prescribed and protected as to its sale by the recognised consensus between practitioner and apothecary, is a source of danger—"a veritable poison to the vaso-motor system," as Dr. Tommasi Crudeli has described its abuse; and that to place it in the power of the ignorant countryman to dose himself with it *ad libitum* is to make a valuable remedy a source of positive disease. In all this there is undeniable force, add to which that the action of the Government in intervening between the public and the apothecary is but another example of its perennial blunder in beginning at the wrong end. Why not drain the marshes and reclaim the derelict lands that breed malaria? Why, in its neglect of this duty, go out of its way to innovate mischievously in the dispensing of a powerful drug which ought never to reach the public except through the combined medium of practitioner and apothecary? To this the Government apologists reply that the apothecary cannot be hurt or compromised where he does not exist; that the Bill contemplates facilitating the sale of the drug in those two-thirds of Italy where malaria is prevalent, but where no druggists' shops are to be found; that while the reclamation of the malarious tracts is not being overlooked, the fever-stricken labourers must in the meantime be protected by a drug which is to them what the Davy lamp is to the miner; and that the Bill is only provisional, remaining in force not a day longer than the rapidly diminishing prevalence of malaria makes it necessary. The controversy is a grave one, and before the Bill passes through committee it will undoubtedly be modified in a sense more favourable to the pharmaceutical interest.

Dec. 16th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera News.

SINCE cholera was first officially discovered it is now exactly two months, and there have been 1010 cases reported, of which 840 have died. This ratio is greatly in excess of the real mortality rate, for it must be remembered that, whereas the deaths cannot be concealed, many slight cases of the disease are never recognised as being anything more important than diarrhœa. Even in England in 1892 and 1893 it was found necessary to make the notification of diarrhœa in cholera districts compulsory, and, moreover, to pay the notifying medical men, before the disease was stamped out. Such notification will be impossible in Egypt for many a long day, because so long as the capitulations exist it is impossible to compel natives protected by foreign Powers to do anything sanitary. The daily bulletins for all Egypt give the following figures for the past week: 34 admissions into hospitals with 33 deaths, and to these, 21 deaths must be added as having occurred outside the hospitals. Cholera seems to have been successfully stamped out of the canal which furnished so many infected villages last month, and at Mansourah the schools have been reopened. Two cases have occurred in one of the native quarters of Cairo, both being children of a man who evidently imported the disease here from Zagazig. He was an itinerant beggar who lived on the precarious bounty of those who were willing to have the Koran read to them. It appears that he went to Zagazig on Nov. 28th, returned to Cairo on the 30th, and died in his miserable lodging here on Dec. 1st. As there was a history of his having suffered from dysenteric diarrhœa for three months, the native medical man who attended him before death certified that he died from chronic dysentery. However, on

[1] Société Médicale des Hôpitaux, Dec. 13th, 1895.

Digitized by Google

Dec. 6th at 10 P.M. his daughter aged eighteen was taken ill, and she died twelve hours later. The case clinically was one of cholera, and bacteriological examination of the ileum confirmed the diagnosis. In the night of Dec. 9th a son of the dead beggar aged seven years was taken ill, and he died at 3 A.M. on Dec. 11th. His case, both clinically and bacteriologically, was also cholera. Immediately the first case was found the house was isolated and the various inmates of it kept under medical observation. As the house consists of several poor tenements, some denizens of which were intending to start for Upper Egypt, Dr. Rogers Pasha has taken the wise precaution of temporarily conveying all the family and the dwellers in this infected house out to the desert at Abbassiyeh, where they will undergo a quarantine of seven days. It is needless to say that all necessary disinfection of the house and its contents, and of the cesspool which was within one yard of the well (not used for drinking water, but often used for various other purposes), has been ably carried out. The heads of the Sanitary Department are personally superintending this work. As the disease is confined to this one house in Cairo there is no reason why it should not be successfully isolated here as it has been in the big towns of Mansourah and Zagazig.

Precautions in Cairo.

Since the beginning of October the Special Sanitary Commission for Cairo has been diligently at work. A great improvement has been made in all surface cleanliness such as the sweeping and scavenging of streets, markets, stables, dairies, &c. This is not an unimportant labour if one remembers that many of the natives have no latrines in their houses and that there are as yet no public closets except those attached to the mosques. The English Commandant of Police tells me he has never seen Cairo look so clean before. The insides of huts and stables have been limewashed, many faulty wells have been closed, and several places in which water is supplied gratis have been erected in Boulak and Old Cairo by arrangement with the water company. The mosque cesspools have been compulsorily emptied by a pneumatic odourless system, and have then been disinfected. The public baths, which have the economical habit of storing up dustbin refuse for fuel, have been restricted to keeping only a supply for twenty-four hours on their premises. If Dr. Rogers succeeds in organising this reform it will be a cheap and salutary way of utilising each bath in the town as a public destructor.

Precautions in Zagazig.

Though Zagazig is now free from cholera, the work of prevention is not being allowed to abate. Wells are being bored in six different parts of the town, and water from them, taken from a depth of thirty feet, is now being analaysed by the Government chemists in Cairo. The transport of milk and cream from all infected districts has now been forbidden.

Cairo, Dec. 11th.

Medical News.

UNIVERSITY OF LONDON.—The following candidates passed the M.S. Examination recently:—

Aldrich-Blake, Louisa B., M.D., London School of Medicine and Royal Free Hospital.
Hamilton, E. T. B., M.D., B.Sc., Guy's Hospital.
Sheen, Alfred William, M.D., Guy's Hospital.

The following candidates passed the B.S. Examination:—

FIRST DIVISION.

Barnard Harold Leslie, London Hospital.
Berry, Frances May D., M.D., London School of Medicine and Royal Free Hospital.
Chaning-Pearce, David Arnold, Guy's Hospital.
Hull, Charlotte Elizabeth, Royal Free Hospital.
Hunt, George Bertram, University College.
Pugh, William Thomas Gordon, Middlesex Hospital.
Russell, Alfred Ernest, St. Thomas's Hospital.
Shaw, Harold Batty, University College.
Sloane, John Stretton, B.Sc., St. Bartholomew's Hospital.
Thomas, Thomas Morrell, Guy's Hospital.
Turner, William, King's College.

SECOND DIVISION.

Appel, Elizabeth Louise C., B.Sc., London School of Medicine and Royal Free Hospital.
Armitage, Frances, London School of Medicine for Women.
Blake, Victor John, University College.
Bodman, John Hervey, University College, Bristol, and St. Bartholomew's Hospital.
Brown, Joseph Norwood, University College.
Byrne, Peter Kevin, B.A., University College.
Corthorn, Alice Mary, London School of Medicine and Royal Free Hospital.
Coutts, Francis James, University College.
De Segundo, Charles Sempill, St. Bartholomew's Hospital.
Dimsey, Alfred, University College.
Evans, Daniel Edward, St. Mary's Hospital.
Every-Clayton, Leopold E. V., Guy's Hospital.
Haines, John William, St. Bartholomew's Hospital.
Handley, William Sampson, Guy's Hospital.
Hopton, Ralph, Yorkshire College.
Hora, Julian, Guy's Hospital.
Horner, William Ernest Leethem, University College.
Hunnard, Arthur, University College.
Jewell, William Henry, Guy's Hospital.
Levick, Harry Driffield, St. Thomas's Hospital.
Martin, Antony Alexander, St. Mary's Hospital.
Miskin, Leonard John, St. Thomas's Hospital.
Paling, Albert, Middlesex Hospital.
Parry, Leonard Arthur, Guy's Hospital.
Richmond, Benjamin Arthur, B.Sc., Guy's Hospital.
Rodocanachi, Ambrose John, B. Sc., University College.
Salter, Alfred, Guy's Hospital.
Smith, Frank Addinsell, St. Bartholomew's Hospital.
Sowry, George Herbert, St. Bartholomew's Hospital.
Steinhæuser, John Robert, Guy's Hospital.

The following candidates passed the M.D. Examination:—

MEDICINE.

Adkins, Albert James, St. Thomas's Hospital.
Bathurst, Lullum Wood, St. Bartholomew's Hospital.
Bennett, Lizzie, London School of Medicine and Royal Free Hospital.
Berry, Albert Edward, Owens College and Manchester Royal Infirmary.
Blomfield, Edward Eldridge, B.S., London and Guy's Hospitals.
Bolton, Joseph Shaw, B.S., B.Sc., University College.
Bunch, John Le Mare, B.S., B.Sc., University College.
Castellote, Ramon Horace, University College.
Cole, Robert Henry, St. Mary's Hospital.
Collyer, Brice, St. Bartholomew's Hospital.
Crowley, Ralph Henry, St. Bartholomew's Hospital.
Eves, Percy Stanhope, B.S., University College.
Gully, Robert Cullum, St. Bartholomew's Hospital.
Hamilton, Richard, Owens College, Manchester Royal Infirmary, and Guy's Hospital.
Jones, Lillie Mabel Agnes, London School of Medicine for Women.
Joseph, Arthur Hill, University College and Royal Infirmary, Bristol, and King's College.
Lane, Clayton Arbuthnot, St. Mary's Hospital.
Lankester, Arthur Colborne, St. Thomas's Hospital.
†Leete, Arthur Henry, B.Sc., Guy's Hospital.
Low, Vincent Warren, B.S., St. Mary's Hospital.
Manning, Guy Eugene, Guy's Hospital.
Meakin, Harold Budgett, St. Bartholomew's Hospital.
Pace, Elizabeth Margaret, London School of Medicine and Royal Free Hospital.
Parsons, Christopher Thackray, St. Mary's Hospital.
Perram, Edward Arthur, St. Bartholomew's Hospital.
†Potts, William James, Owens College and Manchester Royal Infirmary.
*Roberts, Charles Hubert, St. Bartholomew's Hospital.
Rogerson, Clement Michael, Yorkshire College.
Shaw-Mackenzie, John Alexander, University College.
Smith, Edwin, St. Thomas's Hospital.
Smith, William Robert, B.S., King's College.
Smyth, Reginald Mander, St. Mary's Hospital.
Soden, Wilfred Newell, St. Bartholomew's Hospital.
Stanley, Arthur, St. Mary's Hospital.
Stedman, Thomas Bernard, University College.
Sturge, Mary Darby, London School of Medicine and Royal Free Hospital.
Ta' Bois, Alfred Charles, St. Bartholomew's Hospital.
Taylor, Edwin Claude, B.S., Guy's Hospital.
Taylor, Frederick Ryott P., B.S., Westminster Hospital.
Warner, Thomas, King's College.
Wells, Sydney Russell, B. Sc., St. George's Hospital.
Williams, Ethel Mary Nucella, London School of Medicine and Royal Free Hospital.
Williams, Samuel, University College.
Woollett, Charles Jerome, Charing-cross Hospital.
Wright, Sydney Faulconer, St. Thomas's Hospital.
Young, Robert Arthur, B.Sc., Middlesex Hospital.

STATE MEDICINE.

Symes, John Odery, St. Mary's Hospital.
Williamson, John, St. Bartholomew's Hospital.

* Gold medal.

† Obtained the number of marks qualifying for the gold medal.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen (whose names are arranged in order of seniority as Members), having passed the necessary examinations and having conformed to the by-laws and regulations, have been admitted Fellows of the College:—

Ferrand, Edward (Surg.-Lieut.-Colonel, I.M.S.), M.D. Durh., L.R.C.P. Edin., St. Bartholomew's Hospital and Durham University; Member, May 19th, 1875.
Foulerton, Alexander Grant Russell, L.R.C.P. Lond., St. Bartholomew's Hospital; July 30th, 1884.
Tanner, Herbert, L.R.C.P. Lond., St. Mary's and St. Thomas's Hospitals; April 28th, 1885.
Pisani, Lionel John (Surg.-Capt., I.M.S.), L.S.A. Lond., Charing-cross Hospital; Jan. 21st, 1886.

Digitized by Google

Ridley, Nicholas Charles, M.B., L.R.C.P. Lond., St. Mary's Hospital; May 10th, 1888.
Lace, Frederick, L.R.C.P. Lond., University College and Royal Infirmary, Bristol; May 9th, 1889.
Leaf, Cecil Huntington, M.B., B.C. Camb., L.R.C.P. Lond., Cambridge University and London Hospital; July 28th, 1890.
Curtis, Henry Jones, L.R.C.P. Lond., University College and Hospital; Feb. 12th, 1891.
Addison, Christopher, L.R.C.P. Lond., St. Bartholomew's Hospital; Nov. 12th, 1891.
Ballance, Hamilton Ashley, M.D., L.R.C.P. Lond., University College and Hospital; Aug. 1st, 1892.
Hainworth, Edward Marrack, M.B., B.S., L.R.C.P. Lond., St. Thomas's Hospital; Aug. 1st, 1892.
Randall, Martin, M.D., L.R.C.P. Lond., University College and Hospital; Aug. 1st, 1892.
Sutcliffe, William Greenwood, L.R.C.P. Lond., St. Thomas's Hospital; Aug. 1st, 1892.
Barnard, Harold Leslie, L.R.C.P. Lond., London Hospital; Nov. 10th, 1892.
Smith, Thomas Rudolph Hampden, M.B. Camb., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; Nov. 10th, 1892.
Turner, William, M.B., L.R.C.P., L.S.A. Lond., King's College and Hospital; May 11th, 1893.
Elworthy, Henry Stuart, L.R.C.P. Lond., St. Bartholomew's Hospital; July 27th, 1893.
Arnold, Gilbert James, L.R.C.P. Lond., St. Thomas's Hospital; Nov. 9th, 1893.
Dickson, Henry Arthur David, L.R.C.P. Lond., St. Thomas's Hospital; Nov. 9th, 1893.
Colby, Francis Edward Albert, M.B. Camb., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; Feb. 8th, 1894.
Brown, Ralph Charles, M.B., Ch B. Melb., L.R.C.P. Lond., Melbourne University and Westminster Hospital; Nov. 14th, 1895.
Brodie, William Haig, M.D. Edin., Edinburgh University, St. Mary's and St. Bartholomew's Hospitals; not previously a Member.

The following gentlemen, having passed the necessary examinations, have been admitted Licentiates in Dental Surgery:—

Baker, William Herbert, Charing-cross Hospital and Dental Hospital of London.
Bascombe, Edwin Cecil Dare, Middlesex Hospital and National Dental Hospital.
Beaumont, Frederick Charles, Guy's Hospital.
Breakell, John James, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester.
Chambers, Thomas Rubens, Guy's Hospital.
Colyer, Stanley William Randolph, Charing-cross Hospital and Dental Hospital of London.
Dawson, William James Oliver, Guy's Hospital.
Denham, Norman, Guy's Hospital.
Dimock, Edward Claude, Guy's Hospital.
Goddard, John Wood, Guy's Hospital.
Händel, Franz Edward, Guy's Hospital.
Hankey, Stanley James, Charing-cross Hospital and Dental Hospital of London.
Harrison, Edward, Charing-cross Hospital and Dental Hospital of London.
Humby, William John, Middlesex Hospital and National Dental Hospital.
James, Benjamin Edgar, Guy's Hospital.
Jepson, Harold Ernest, Charing-cross Hospital and Dental Hospital of London.
Jones, Frederick Warner, Charing cross Hospital and Dental Hospital of London.
King, Herbert, Guy's Hospital.
Lees, Tom, Charing-cross Hospital and Dental Hospital of London.
Lewis, James William, Guy's Hospital.
Ludbrook, Stephen Percy, Charing-cross Hospital and Dental Hospital of London.
Macdonald, George Ernest, University College, Liverpool, Charing-cross Hospital and Dental Hospital of London.
McKay, Robert, Middlesex Hospital and Dental Hospital of London.
Marston, Walter, Middlesex Hospital and Dental Hospital of London.
Mathews, Harold Dewe, Guy's Hospital.
Payne, Joseph Lewin, Guy's Hospital.
Pidgeon, Walter Herbert, Charing-cross Hospital and Dental Hospital of London.
Relph, Herbert John, Middlesex Hospital and National Dental Hospital.
Robertson, Harry Lennox, Mason College, Queen's and General Hospitals, and Birmingham Dental Hospital.
Rose, Samuel Frank, Middlesex Hospital and Dental Hospital of London.
Ryle, Arthur Buxton, Guy's Hospital.
Seccombe, Clovis Leopold, Middlesex Hospital and Dental Hospital of London.
Spencer, George Ross, Charing-cross Hospital and Dental Hospital of London.
Turton, Arthur William, Charing-cross Hospital and Dental Hospital of London.
Veitch, William MacGregor, University College, Royal Infirmary, and Dental Hospital, Liverpool.
Wood, James, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester.

Seventeen gentlemen were referred for six months

FOREIGN UNIVERSITY INTELLIGENCE.—*Cracow:* Dr. Wicherkiewicz of Posen has been appointed Professor of Ophthalmology.—*Genoa:* Dr. Mostiari of Siena has been appointed Professor of Surgical Pathology.—*Naples:* Dr. Aniello has been appointed Extraordinary Professor of Orthopædi Surgery.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Tepliasin of Kazan, a well-known ophthalmologist.—Dr. G. H. Van der Mey, Professor of Midwifery and Gynæcology in the University of Amsterdam, from septicæmia following an operation.—Dr. Fauvel, a distinguished Parisian laryngologist whose opinion it was intended to have obtained in the case of the late Emperor Frederick, at the age of sixty-five.

PRESENTATIONS.—Mr. T. M. Wills, L.R.C.P., L.M., F.R.C.S. Irel., on the annual distribution, at Bootle, on the 13th inst., of certificates and medallions to the Bootle Fire Brigade and the police force in connexion with the St. John Ambulance Association, the mayor of the borough presiding, was the recipient of a portrait of himself, as a mark of appreciation of his services to the ambulance classes.—Dr. D. Mitchell, who has for the past fifteen years been in practice in Renton (Dumbartonshire) and has taken a prominent part in the public and political life of the district, has been presented with a purse of sovereigns on the occasion of his leaving Renton.

DIPHTHERIA IN LONDON.—Last week the registered deaths from diphtheria in London numbered 63, whereas the numbers in the three weeks preceding had been respectively 69, 63, and 69. The total last week was 20 in excess of the average for the fiftieth week of the years 1885-94. The deaths, as has now for some long time been the case, were nearly all in young persons of under twenty years. The week saw also deaths registered in Greater London, the larger share being credited to West Ham and to the Edmonton Union. In these two localities the disease seems to be especially fatal. The figures concerning notification of diphtheria in London are now before us for the four weeks ended with the last day of November. They show that every one of the sanitary areas of the county of London, excluding the port district, was invaded by diphtheria. The notifications in gross amount show a slight decline over the previous four weeks ended Nov. 2nd. The total notifications in the earlier period, 1305, have given place to 1269, and the weekly average of 326 to 317. On the other hand, whilst in the earlier period eight districts with over fifty notifications respectively had an aggregate of 655, in the later period ten districts had respectively over 50 notifications and a total of 734. Thus we have to face a weekly list of upwards of 300 notified attacks.

THE SANITARY INSTITUTE, PARKES MUSEUM, MARGARET STREET, W.—At a sessional meeting of the Sanitary Institute held at the Parkes Museum, Margaret-street, W., on Wednesday, Dec. 11th, Sir Benjamin Baker, K.C.M.G., LL.D., F.R.S., in the chair, Sir Douglas Galton, K.C.B., LL.D., F.R.S., read a paper on the Lessons to be learned from the Experimental Investigations by the State Board of Health of Massachusetts upon the Purification of Sewage. After dealing with the various systems of sewage filtration, he described the systems devised for the aeration of the filters, dealing more particularly with experiments made by Colonel Waring at Newport, New York. He summed up the conclusions to which the various experiments lead as follows: 1. The suspended matters of sewers (sludge) can be mechanically withheld by straining slowly through suitable material. 2. The filth accumulated by this straining material can be destroyed, and the straining medium restored to a clean condition by mere aeration. 3. The successive alternate operations of fouling and cleansing can be carried on indefinitely without renewal of the straining material. 4. The purification obtained by this straining process practically equals that accomplished by chemical precipitation, and is sufficient to admit of discharge into any considerable body of water not used as a source of domestic supply or for manufacturing purposes requiring great purity. 5. Such filters can be maintained in *constant* and *efficient* operation by suitable aeration. 6. The erection of a plant capable of purifying large volumes of sewage upon a relatively small area calls for no costly construction. Repairs and renewals are merely nominal. The attendance required is but slight. There is no outlay for chemicals, &c. The only expense of mechanical operation is the driving of the blower or air-compressor. 7. The process admits of wide variation in the selection of filtering material, and nearly every community can find in its local resources something suitable for the purpose.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BOWES, WM., M.R.C.S., has been appointed Medical Officer for the Sixth Sanitary District of the East Ashford Union.

BRIMACOMBE, R. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for Kingswood, vice H. Grace.

BURMAN, W. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Wath and North Rotherham Joint Hospital.

DOWLING, G. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Alderley Edge Urban District Council.

EDDOWES, ALFRED, M.D. Edin., has been appointed a Physician to the St. George's and St. James's Dispensary, King street, Regent-street, W.

FRIEL, R., M.B., B.Ch., L.M. Irel., has been reappointed House Physician to the Richmond, Whitworth and Hardwicke Hospitals, Dublin.

HOGG, J. A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Shardlow Sanitary District of the Shardlow Union.

LEWIS, FREDERICK W., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to the General Infirmary at Gloucester and the Gloucestershire Eye Institution.

MORTON, A. C., M.R.C.S., has been reappointed Medical Officer of Health for the North Walshem Urban Sanitary District.

O'CONNELL, J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Senior Assistant Medical Officer for the Workhouse of the Township of Toxteth Park.

SHEKA, J. B. P., L.R.C.S., L.R.C.P., L.M. Irel., has been appointed House Physician to the Richmond, Whitworth and Hardwicke Hospitals, Dublin.

STANLEY, H., M.B., B.C. Camb., has been appointed Medical Officer for the Fifth Sanitary District of the East Ashford Union.

STEPHENSON, SYDNEY, M.B., F.R.C.S.E., has been appointed Ophthalmic Surgeon to the North-Eastern Hospital for Children, Hackney-road, Shoreditch.

SWORDER, H., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Luton.

TAYLOR, H. H., F.R.C.S., M., L.R.C.P. Lond., has been appointed Assistant Surgeon to the Royal Alexandra Hospital for Sick Children, Brighton, vice Morgan.

THOMPSON, H. E., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the General Infirmary at Gloucester and the Gloucestershire Eye Institution.

TIBBETTS, T. M., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health by the Quarry Bank Urban District Council.

WAGSTAFF, J. P., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Pelham Sanitary District of the Bishop Stortford Union.

WALSH, LESLIE H., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Royal Mineral Water Hospital, Bath, vice Wohlmann, resigned.

WALTER, E. W., L.R.C.P. Edin., L.M., M.R.C.S., has been appointed Medical Officer of Health by the Shoeburyness Urban District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRIDGNORTH AND SOUTH SHROPSHIRE INFIRMARY.—House Surgeon for one year. Salary £80, with board and lodging in the infirmary, and a certain fee for attending the in- and out-patients under the direction of the Honorary Surgeons. Applications to the Hon. Secretary, Oldbury Rectory, Bridgnorth.

BRIGHTON AND HOVE LYING-IN INSTITUTION AND HOSPITAL FOR WOMEN, West-street, Brighton.—House Surgeon, unmarried. Salary £80 per annum, with furnished quarters and board, gas, coals, and attendance.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's-inn-road, W.C.—Three Assistant Registrars.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistantships.

CHORLTON-UPON-MEDLOCK DISPENSARY, Manchester.—Resident House Surgeon, unmarried. Salary £100 a year, with furnished rooms and attendance.

CITY OF LONDON UNION INFIRMARY.—Dispenser at the Infirmary, Bow-road, E. Salary £100 per annum and dinner daily. Applications to the Clerk to the Guardians, 61, Bartholomew Close, E.C.

COUNTY BOROUGH OF CARDIFF.—Resident Medical Officer, unmarried, for the Borough Hospital for Infectious Diseases, for one year. Salary £50 per annum, with board (without stimulants) and residence in the hospital. Applications to Dr. Walford, Medical Officer of Health, Town Hall, Cardiff.

COUNTY BOROUGH OF WIGAN.—Medical Officer of Health and Medical Superintendent of the Sanatorium. Salary £225 per annum, payable monthly. Applications to the Town Clerk, Municipal Buildings, Wigan.

EDMONTON UNION.—Medical Officer at the Chase Farm Schools, Enfield. Salary £80 per annum. Applications to the Solicitor and Clerk, The Grange, White Hart-lane, Tottenham.

HOLLOWAY SANATORIUM HOSPITAL FOR THE INSANE, Virginia Water.—Junior Assistant Medical Officer (lady) for the ladies' side. Salary £100. Applications to Dr. Phillips, Virginia Water.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Four Clinical Assistants in the out-patient department, and four Clinical Clerks to the in-patient physicians.

KING'S COLLEGE, London.—A Demonstrator in the Bacteriological Laboratory.

LIVERPOOL DISPENSARIES.—Assistant Surgeon, unmarried. Salary £80, to be increased to £90 per annum after the first year's service, with apartments, board, and attendance. Applications to the Secretary, 34, Moorfields, Liverpool.

OWENS COLLEGE, Manchester.—Junior Demonstratorship in Physiology and Histology. Annual salary £100.

POPLAR AND STEPNEY SICK ASYLUM DISTRICT.—Second Assistant Medical Officer. Salary £80 per annum, to be increased by yearly increments of £10 to a maximum of £100, with rations, furnished apartments, and washing. Applications to the Clerk to the Managers, Bromley, Middlesex, E.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Marylebone-road, N.W.—Surgeon to the out-department.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W.—House Surgeon, for twelve months. An honorarium of £50 per annum, with board and lodging in the hospital. Also House Physician to the in-patients, for eight months. An honorarium at the rate of £50 per annum, with board and lodging in the hospital.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Resident Assistant for six months. Board, lodging, and washing provided.

YORK COUNTY HOSPITAL, York.—Assistant House Surgeon. Salary £60 per annum, with board, rooms, washing, &c.

Births, Marriages, and Deaths.

BIRTHS.

BLATCHLEY.—On Dec. 10th, at Evelyn-street, Deptford, S.E., the wife of J. B. Challands Blatchley, L.R.C.P., L.R.C.S. and L.M. Irel., of a daughter.

MCCAUSLAND.—On Dec. 17th, at Swanage, Dorset, the wife of A. McCausland, M.D. Brussels, of a son.

SKELDING.—On Dec. 8th, at Bedford, the wife of Henry Skelding, M.B. Camb., of a daughter.

TAIT.—On Dec. 11th, at Highbury-park, the wife of Edward Sabine Tait, M.D., of a son.

MARRIAGES.

HUDSON—BIRD.—On Oct. 21st, 1895, at St. Peter's Church, Mossel Bay, Cape Colony, by the Venerable Archdeacon Fogg, Francis Joseph Hudson, M.B. Aberd., District Surgeon, George, third son of the late John F. Hudson, Mossel Bay, to Bessie Bird, eldest daughter of the late Captain George B. Bird, R.N.R.

SCOTT—CLEVELAND.—On Dec. 17th, at St. James's, Kidbrook, Patrick Cumin Scott, M.B. Cantab., M.R.C.S. Eng., youngest son of James Nairne Scott, Esq., Blackheath, to Alice Adelaide, younger daughter of the late Henry Cleveland, Esq., Solicitor to Government, Bombay.

SENIOR—WESTALL.—On Dec. 17th, at St. Cyprian's, Lewisham, Robert W. Senior, M.R.C.S., L.R.C.P., late Surgeon R.N., son of the late Joseph Senior, of Streatham, to Helen Maud, daughter of William Mawley Westall, of St. John's Lodge, Brockley.

SWANTON—DOE.—On Dec. 18th, at St. Michael's Church, Cornhill, James Hutchinson Swanton, M.D. Irel., M.A., to Sophia Doe, niece of the late Joseph B. Doe, J.P., D.L., of Edmonton.

DEATHS.

AMYOT.—On Dec. 15th, at Diss, Norfolk, Thomas Edward Amyot, F.R.C.S., aged 78.

BROOKES.—On Dec. 10th, at Much Wenlock, Shropshire, William Penny Brookes, F.R.C.S. Eng., J.P., in his 87th year.

CHANDRA.—On Dec. 14th, in London, Brigade Surgeon-Lieutenant-Colonel Rajendra Chandra Chandra, late Professor, Medical College, Calcutta.

HANBURY.—On Dec. 11th, at The Oaks, Sidcup, Kent, Richard Savill Hanbury, M.D. St. And., formerly Surgeon 2nd West York L.I. Militia, and of Peterborough.

MARTINE.—On Dec. 11th, at Weston, Haddington, N.B., William Martine, M.D. Edin.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

MEDICAL OFFICERS OF HEALTH AND THEIR TENURE OF OFFICE.

Mr. W. J. F. Churchouse, L.R.C.P. Edin., &c., medical officer of health to the Rural District of Daventry, sends us a lengthy communication from which it is quite evident that, owing to proper and honourable performance of his duty under the orders of the Local Government Board, he has fallen under the displeasure of people who prefer no sewers and a dirty water-supply to decent sanitation which will involve some cost; and now another officer has been elected in his place. Mr. Churchouse also sends us a correspondence with the Local Government Board on the subject, in which he expresses his astonishment that the central authority, whose "approval" is necessary to every appointment, as regards which they certify for repayment of half the salary by the County Council, should not uphold him as health officer. Our correspondent's case, unfortunately, is only one of many others, and as the law now stands we do not see how matters can be mended. He was only appointed up to a certain date. When that date arrived the post was legally vacant, and it rested absolutely with the district council to appoint him again or to appoint someone else. It is true that the Public Health Act gives power of "approval" to the Local Government Board; but this approval has not to do with the individual appointed, unless, indeed, it can be shown that he is morally or physically unfit to perform the duties. It is mainly concerned with the possession of proper medical qualifications and with the assignment of a reasonable salary. No statute gives the Local Government Board power to impose an individual medical officer of health on any authority having the statutory power of making a fresh appointment. Indeed, we do not see how it could be otherwise; the responsible authority must have the responsibility of selecting its own officer. But, once appointed, he should be upheld; and it is for this reason that we gladly see that the Local Government Board now urge authorities to make most of these appointments either for a long term of years or for life, during which period of appointment the holders cannot be removed, except with the Board's sanction. We deeply regret the circumstances attaching to our correspondent's case. It affords an additional reason for demanding of Parliament that, as regards tenure of office during good behaviour, provincial medical officers of health should be placed in the same position as that attaching to metropolitan officers of health.

WILLIAM III. AND HIS PHYSICIANS IN 1700.

THE following is the account of the post-mortem examination performed upon William III. after the illness referred to in our issue of Nov. 23rd:—

Report of the Physitians and Surgeons, comanded to assist at the dissection of the Body of the late King.

Upon the first view of the Body, before dissection, the following appearances were remarkable.

The Body in generall was much emaciated; Both the Legs up to the Knees and a little higher, as also the right hand and arm as far as the Elbow, were considerably sweld.

There appeared likewise on the left thigh near the Hipp, a bladder full of water, of the bignesse of a small Pullet's Egg, ressembling a Blane.

Upon opening the Belly, the Guts appeared of a Livid colour, and the bloud contained in the vessels there of blackish: The gutt called Jlion had in some places, the markes of a slight Jnflammation.

The Pancreas, Mesentery, Liver, Gall Bladder, Spleen, Kidneys and Stomack, were all sound and without fault.

Jn the Thorax or Chest wee observed, that the right side of the Lobes of the Lungs adhered to the Pleura, and the Left, much more, from which upon separation, there Jssued forth a quantitie of Liquor judged to be purulent or frothy serum: The upper Lobe of the left side of the Lungs and the part of the Pleura annext to it, were inflamed to a degree of mortification: And this wee looke upon as the immediate cause of the King's death.

ffrom the ventricles of the Heart and the great bloud vessels issuing out of them were taken severall large tough ffleshlike substances of the Kind called Polliposer.

The Heart was of the smaller size, but firm and strong.

Upon laying bare the right Collar bone, wee found that it had bin broken neare the shoulder and well sett, some Extravasated bloud was lodged above and below the ffracture.

The Brain was perfectly sound and without any signe of distemper.

Jt is very rare to find a Body, with so little bloud, as was seen in this, there being more in the Lungs, than in all the parts besides putt together,

Signed

HUTTON BLONDMORE
MILLINGTON BIDLOO
[and others]

Delivered to ye Queen and Councell, March ijth, 170½

Endorced—"Dissection of the Late King's Body." In writing of a later date and in different coloured ink, similar to the signatures—"To His Grace the Duck off Queensburry, &c., &c."

Mr. Thos. Jackson is thanked for his communication. If he will take counsel with his medical man, and present the facts to us properly attested by that gentleman, we shall be happy to give them consideration.

"A QUERY."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent, "Zambaan," *re* strychnine in snake poisoning, may I be allowed to say that the treatment, according to Dr. Muller, is to inject, in urgent cases, ½ gr., in milder ones ¼ gr. every half-hour until the effects of the snake poison are completely removed, and is perfectly safe practice which none who follow it will have cause to regret. A very small dose will then suffice to produce slight muscular spasms, and, to make doubly sure, a glass or two of whisky-and-water will show by their exhilarating effect that all danger is past. In a very bad case I had the patient was in a state of coma when I saw him; so I commenced by injecting fifteen minims of liqour strychniæ B.P., and twenty minutes afterwards injected a similar amount, both in the neighbourhood of the bite. Altogether I was obliged to inject sixty-five minims of the liquor—the largest quantity ever used up to that date (April, 1890). Messrs. Burroughs, Wellcome, and Co. of Snow-hill make the requisite tabloids, which are very convenient to carry; but I used the liquor strychniæ B.P. with good results for some years, and generally combined it with a little cocaine.

I am, Sirs, faithfully yours,

E. ST. GEORGE QUEELY,
formerly Government Medical Officer, Maytown District, North Queensland.

Dec. 16th, 1895.

VANISHING CUSTOMS.

To the Editors of THE LANCET.

SIRS,—I am endeavouring to obtain for scientific purposes trustworthy evidence concerning customs and superstitions connected with death and burial; and it has been suggested to me that there are many medical men in villages and country places all over the United Kingdom who often come across odd, old-world customs, sayings, and superstitions, especially among the peasantry and labouring classes, and who, if they knew that these were of value, would be glad to forward a note of them. You will be conferring a favour on me if you will allow me to make known through your columns that I shall be most grateful for any such information, and that I shall be happy to acknowledge the kindness of my correspondents in any use I may make of their communications. I am, Sirs, yours obediently,

Highgarth, Gloucester, Dec. 4th, 1895. E. SIDNEY HARTLAND.

"THE CLIMATE OF THE EAST COAST OF AFRICA."

To the Editors of THE LANCET.

SIRS,—In reply to the inquiry of "Voyager" regarding the climate of the east coast of Africa permit me to say that it depends on how long he proposes to be on the coast, and how much time he proposes to stay on shore at the places he mentions, and whether it includes little shooting excursions up the rivers. Speaking generally, he may voyage along the coast from Natal to Zanzibar, calling at every port, and even spending a few hours on shore at each place, provided he sleeps on board at night, and suffer no ill consequence whatever. I speak with an experience of over three years on the east coast, the Zambesi river, and Lake Nyassa. I have not put in at all the coast ports, or, indeed, at most of them; but I have sailed from the Cape to Aden, calling at the principal ports, and I have no hesitation in prophesying a very pleasant, safe, and interesting trip for "Voyager" and his friends, and my only regret is that I am not to be one of the party.

I am, Sirs, yours faithfully,

T. THORNTON MACKLIN, M.D.

St. Mary's, Isles of Scilly, Cornwall, Dec. 16th, 1895.

P.S.—If your correspondent would like to make further inquiries, I shall be happy to respond.—T. T. M.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, "Voyager," I can reassure him that a trip by sea from Natal to Zanzibar is free from danger of fever, although the temperature will be pretty hot at this time of year. Travelling along the edge of the coast itself, or at sea within a couple of miles, would not have been so safe at the commencement of the wet season now past. I am, Sirs, yours faithfully,

Cromwell-road, S.W., Dec. 13th, 1895. ROBERT J. COLENSO.

To the Editors of THE LANCET.

SIRS,—In reply to "Voyager's" letter I may mention that while acting as surgeon in the Union Steam Ship Co.'s service, in 1893 and 1894, I went twice along the east coast from Cape Town to Zanzibar. The voyage is by no means unhealthy for those coasting. I never had fever myself, nor did I know of any cases of fever acquired by officers or crew while coasting. Delagoa Bay and Beira are not particularly healthy places for permanent abode; but there is no fear of getting malarial fever while living on board a vessel during her stay at these places, nor is one precluded from landing for a short time by the climate. The people who get malaria are those who are compelled to live on shore for some time. If your correspondent cares to communicate with me, I shall be happy to give him any further information I can. I am, Sirs, yours faithfully,

Dec. 17th, 1895. SETH.

To the Editors of THE LANCET.

SIRS,—In reply to "Voyager" allow me to say that part of the littoral of East Africa—namely, Natal to Zanzibar—is particularly unhealthy, for it includes the worst governed part of Africa—the Portuguese territory. The sandy soil is permeated with miasmata, and the sanitary arrangements are most primitive. Delagoa Bay is very deadly to Europeans, and also another large place, Quilimane, higher up. I have visited every town on the east littoral of Africa from Cape Town to Aden. At Delagoa Bay I found the medical man and the Consul laid up with fever. The former told me it was a hell upon earth, and was much surprised that I had come ashore with my patient, with whom I was travelling round the world *vid* the east coast of Africa. I have an exhaustive account of my trip along this coast, and shall be pleased to give your correspondent any information about this littoral. The steamship service is very good, the officers of the companies—the Donald Currie line and the British Indian line—being particularly civil and obliging. Mosquitoes (particularly at Quilimane) are very troublesome. By "delicate" health I conclude "Voyager" uses the word in every sense. I am, Sirs, yours truly,

J. F. BRISCOE,
Medical Superintendent, Westbrooke House Asylum,
Dec. 14th, 1895. Alton.

To the Editors of THE LANCET.

SIRS,—I saw on Saturday night "Voyager's" letter in THE LANCET and in reply thereto I beg to offer the following observations. I returned from Zanzibar a few months ago, having been in charge of the English hospital there connected with the Universities Mission to Central Africa. I do not think one can advise anyone to go to Zanzibar simply for pleasure, more especially a delicate person. There is a great deal of malaria there, and in March, just at the end of the hot season, I expect, as was the case last year, dysentery will be rife. The rainy season usually begins about the end of March, and at the end of it the most unhealthy time of the year sets in. Some people, of course, have fever mildly, but a serious attack very often leaves lasting effects. Further, there is really nothing in Zanzibar to make it worth while to go there. The island is pretty; but there is nothing of interest beyond the beautiful church built by Bishop Steere. To one who lives and has work in the place it is, of course, different, but to a casual visitor there are no attractions. The hotels also are very bad. The English community there is fairly large and very hospitable; so that in this way visitors to the island generally have a pleasant time. The Delagoa Bay fever is, I believe, even worse than that of Zanzibar, and the place, from all I have heard about it from those who have been there, is very dreary. The climate of Zanzibar is very hot and very damp, somewhat resembling that of a fern-house at home. Mosquitoes abound. Prickly heat and boils also are often the lot of new-comers. Altogether, it is scarcely the place to go to for a pleasure trip, although people who live there like it and manage to be very happy there, in spite of its drawbacks. I am, Sirs, yours faithfully,

Norfolk street, Strand, W., Dec. 16th, 1895. MARGARET BREAY.

"TESTICLE *v.* SWEETBREAD."

To the Editors of THE LANCET.

SIRS,—The letter on the above subject in your issue of Nov. 30th has just been brought to my notice. I should like to mention, for the information of Mr. J. Miller, that in this part of the country testicles, especially those of lambs, are a very common dish indeed. I have myself seen farm labourers, when they have been castrating the male lambs, frequently eat them as they draw out the testicles. The lamb is held up by one man, whilst another takes up the skin of the scrotum and snips off a bit of the wool; he then makes a vertical nick in the skin and through the tunica vaginalis, and, pushing the testicle through the opening, draws it out with his teeth. He then either eats it, puts it carefully on one side, or else throws it on the ground, when, if any dogs are about, it is quickly eaten up by them. I am informed by those who have partaken of this dish (cooked in milk) that it is simply delicious; but I, for one, should not care to partake of it.

I am, Sirs, yours faithfully,

J. T. ROGER MILLER,
Malton, Yorks, Dec. 17th, 1895. Fellow, Obstetrical Society, London.

Pharmaceutical Products of High Repute.

THE KEPLER SOLUTION.

The method of dissolving cod-liver in malt extract was originally discovered by us, and although many attempts have been made to imitate our product they have all proved abortive. It is the only preparation that provides a rational means of administering cod-liver oil. It is a real solution, not a mixture, no globules of oil being visible under the microscope. The oil being in a state of solution, its digestion and assimilation are practically secured. Sensitive patients—

even children—positively relish it, the sensation to the palate being more like that of sweet cream than cod-liver oil.

This is an important point to remember, because there are many emulsions thrust on the market which are mere gummy messes or alkaline soaps. In either case the acid juices of the stomach reduce the oil to its original form. Derangement of the digestive tract invariably follows, causing so great a revulsion of feeling that the patient refuses to go on with the oil under any circumstances.

THE LANCET adds its tribute of praise:—"Many can take it easily who cannot take the oil."

Supplied to the Profession in bottles at 1/8 and 3/- each.

MENTHOL SNUFF (B., W. & CO.).

This preparation has become deservedly celebrated for its marked local anæsthetic, vascular-stimulant, and antiseptic properties. It has been approved by the highest medical authorities for its sedative action on the nerve terminations, and for its property of causing prompt contraction of the relaxed nasal vessels. It is composed of menthol, cocaine (¼ per cent.), ammonium chloride, camphor, and lycopodium. It has been suggested to us that the issue of a smaller size would increase the sphere of its usefulness, and we have accordingly decided to issue a -/6 tin in addition to our older 1/- size. Supplied to the Profession in attractive tin boxes at -/5 and -/8 per box.

SACCHARIN "TABLOIDS."

The absolute harmlessness of Saccharin has been conclusively proved by numerous and thorough scientific experiments and researches. It has been shown that Saccharin produces no injurious effects whatever upon the body; that it is discharged, unchanged and in its entirety, through the urine and fæces; that it is absolutely inoperative as a retarding agent on bodily functions; for instance, it exercises no influence on either assimilation or digestion. When, therefore, sugar (the ordinary carbohydrate) in any form is prohibited as an article of food, or as a condiment, it may be asserted, without fear of contradiction, that Saccharin, while satisfying the palate of the patient, cannot possibly aggravate the existing malady; on the contrary, its antiseptic influence may be for good. Saccharin is invaluable as a sweetening agent for unpalatable medicines where sugar is contra-indicated, or where it is desired to make the volume of medicine as small as possible. In the form of soluble Saccharin powder it is sent out in little oval bottles with a tiny spoon attached to the stopper, each spoonful holding an equivalent in sweetening potency to one lump of loaf sugar. The many varieties of gluten food, such as gluten bread, biscuits, &c., may be conveniently and pleasantly flavoured by means of this preparation. Perhaps a more palatable and convenient form of soluble Saccharin is the "Tabloid" prepared by compressing this chemical. "Tabloids" are of the greatest convenience to those travelling or away from home during the day, as each tiny "Tabloid" is equivalent to a lump of sugar and may be substituted for that flavouring agent for sweetening tea, coffee, &c. Soluble Saccharin Powder is supplied to the Medical Profession in ¼-oz. and 1-oz. bottles with scoop, at 1/2 and 3/10 per bottle. Saccharin "Tabloids," containing ½ grain in each are supplied in bottles of 100 and 200 at -/7 and 1/1 each.

"EMOL-KELEET."

Since our earlier notices to the medical profession regarding this preparation we have received many encouraging reports of the beneficial effects of its use in Surgery and Dermatology. It has been prescribed not only for its absorbent, antipruritic, and emollient qualities, but also as a diluent for such antiseptic agents as Loretin, Dermatol, Iodoform, Boric Acid, Chrysophanic Acid, Hydro-Naphthol, &c. Owing to the fact that it is a natural powder containing a large proportion of native silicates, "Emol-Keleet" is chemically stable, and is therefore freely prescribed as a diluent for potent medicinal agents without fear of combination taking place. In addition to these chemical advantages, its soft, silky texture, soothing influence, and other physical qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other drying and dusting powders have failed.

THE LANCET, in an appreciative notice of this preparation, says:—"On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

BRAITHWAITE'S RETROSPECT OF MEDICINE eulogises it as: "The most beautiful, impalpable mineral powder with which we are acquainted, and promises to supersede all the older forms of dusting powder."

Price to the Medical Profession, -/9 per box.

NOURRY IODINATED WINE.

The only Preparation of Iodine which is **uninjurious to the digestion.**

The only Preparation of Iodine of agreeable taste and easily given to children.

AN EXCELLENT SUBSTITUTE FOR COD LIVER OIL AND IODIDES.

Prescribed by eminent Physicians to **lymphatic** and **scrofulous children;** to adolescents for **troubles associated with growth, amenorrhœa,** &c.; to adults for **asthma, emphysema, syphilis,** &c., to **convalescents from infectious diseases,** &c.

THE LANCET OF JANUARY 6TH, 1894, SAYS:—

"This interesting preparation demands some attention and consideration since it claims to offer a means of presenting iodine in a form that is devoid of metallic taste, permanent in character, not giving rise to disagreeable effects, and yet yielding the element in a free state when ingested."

After explaining the difficulty of extracting all the iodine, THE LANCET analysis proved that the wine contains no free iodine and yielded 2·5 gr. of iodine per 1000 c.c.

"In view of these results we regard this wine as an introduction of distinct importance in therapeutics, since it appears to place the use and administration of a valuable medicament on a more satisfactory basis than heretofore. Iodine has been sparingly employed hitherto, on account of its irritant and other disagreeable properties; the above preparation, therefore, which contains no free iodine, but which yields it in full quantity on the slightest provocation, is calculated to lead to more extended application. It certainly deserves trial."

NOURRY'S IODINATED WINE *is* **not** *advertised to the Public; it owes its success entirely to the Medical Profession.*

Price 3/6 per Bottle. Special terms for Physicians.

An Address
ON
"DOCTORS AND SHORTHAND WRITING."

Delivered at the Conference of the National Federation of Shorthand Writers' Associations held at Liverpool on Aug. 3rd, 1895,

BY NORMAN PORRITT, M.R.C.S. ENG., L.R.C.P. LOND.,
HON. SURGEON TO THE HUDDERSFIELD INFIRMARY.

MR. CHAIRMAN AND GENTLEMEN,—Is shorthand of any value to members of the medical profession? Such is the question I am here at your invitation to answer, and I begin my task by making an observation which is applicable to any of the learned professions—not the least of the advantages possessed by shorthand is the mental training required to learn it.

I see from time to time wonderful examples of pupils who have learnt shorthand in the phenomenally short space of a few weeks. But I submit that this estimate cannot apply to the majority of learners, to those who, with average intellects, have to make up for the want of transcendent ability by laborious plodding. For a number of years I taught shorthand at the Huddersfield Technical School, and whilst the learners' class numbered more than 100, with an average attendance of 80, the advanced class never exceeded 30 members, with an average attendance of about 20. Although the elementary class, should have been the feeder of the advanced I assume that it failed to be so because a large number of pupils had not the mental grit to battle through the certain amount of drudgery which is as necessary in the case of shorthand as in the acquirement of most other things of any value in this world. I look upon a youth who has mastered phonography as having gone through a course of self-discipline which is the best possible preliminary to the severer curriculum of any learned profession. I am not contending that phonography is difficult to learn, because that is not the case, but I do maintain that its acquirement calls for self-denial and dogged perseverance, qualities which cannot be displayed or acquired too early, whilst the ample reward which phonography returns to those who woo it steadily and surely is a self-learnt object lesson of the value of perseverance far more precious than any to be gained from pounds of precept or tons of example.

Observing in passing that the scientific basis, the philosophical character, and the geometrical beauties of phonography cannot fail to quicken the intelligence and widen the mental outlook, we shall find that our subject divides itself into the use of shorthand by the student and its use by the practitioner. The medical student prepares for his examinations and the practice of his profession by attending the lectures and demonstrations of his professors and teachers, by his own private study and reading, and by making observations and gaining knowledge in the dissecting-room, in different laboratories, in the wards and the out-patient rooms of the hospital, in the operation room and the post-mortem theatre, and possibly in the homes of the sick. In these different departments of his work and training he sees and hears many things of the utmost value to him in preparing for his examinations and for his life's work as a practitioner. His teachers have been students like himself, and for his benefit they present their offerings of knowledge and give him the results of their experience in well-arranged masses capable of ready assimilation. To preserve these precious lessons the student probably begins to take notes, and it is not necessary before this gathering of shorthand writers to emphasise the advantages which the shorthand writer has over his lumbering longhand brother. Fortunately for the student, to obtain the benefits of shorthand it is not necessary to be a swift writer, as verbatim notes, at any rate, of the lectures the student attends during the first two years of his career, are not necessary. One who starts his student career with a sound knowledge of, and the ability to use without hesitation, the easy reporting style of phonography at a speed of not less than sixty words per minute will find in the lectures he attends abundant opportunity for reporting practice. And the daily practice, added to the evening revision of his notes, will imperceptibly lead to an improved style of writing and a higher rate of speed, until advancing in his career the student reaches the lectures dealing with the proper subjects of his life's work, when he will be able to take down as much or as little as he desires of the words of men whose utterances are received by the whole profession with a respect due to the knowledge which has inspired them. And when in the quiet of his room the student goes over his notes, putting in vowels here and there, giving clearness to doubtful outlines and precision to ambiguous statements, the tone and style, the peculiarities, and mannerisms of the lecturer come back to him, and the impression made by the spoken words is deepened and intensified in a manner to which the longhand writer, with his laboured inconsequent jottings, is altogether a stranger. Many of the lectures are illustrated by diagrams or experiments, and a great advantage of shorthand is that it enables the student, whilst he is securing in his notebook the gist of the lecturer's explanations, to watch the experiment or examine the diagram. In such a case the longhand writer must either cease note-taking or miss some part of the practical lesson the professor is enforcing by his diagram, specimen, instrument, or experiment. And, as Dr. Gowers has pointed out, shorthand enables a student to subsequently make a rough copy of anything he sees into a finished picture by the ease with which shorthand descriptions are added to the imperfect drawing made during the demonstration or lecture. In other work, whether it be at the bedside taking notes of the condition of patients, in the out-patient room noting the features of the ailments to be seen there, in the ward listening to the comments of the physician or surgeon as he makes his round, in the operation room noting the surgeon's cunning in the details of an operation, in the post-mortem room with its grim, useful lessons, in the reading-room making notes from journals and works of reference, or in the quiet of his own room pouring over his books, the advantages of shorthand become more and more manifest.

If money is an object—and there are few to whom it is not—shorthand may obviate for the student the necessity of some text-books. In the "Use of Shorthand by the Student" issued by the Society of Medical Phonographers, Dr. Gowers tells us that, relying only on the shorthand notes of the lectures he attended—to the exclusion of text-books—he won the gold medal on taking his degree. Granting that Dr. Gowers embodies in himself that combination of ability and industry which is said by some to be the same thing as genius, it is tolerably sure that he could not have achieved this triumph without the aid of some form of quick writing, of which none is better than phonography. And this brings us to what is perhaps the most important feature of shorthand in medical work—its educational influence. Shorthand not only enables a student or medical man to work better, but to do better work. The act of writing becomes a pleasure instead of a tedious drag, and the mental processes evolved by the record of facts induce, to quote the words of Dr. Gowers, "a habit of quicker discernment," whilst the revision of the notes compels "a habit of looking out for the significance of the facts and of their relation to knowledge previously obtained. The power of seeing with the mind as well as with the eye becomes developed more and more, and its cultivation lays the foundation for an increased capacity, and even for an ability that would not otherwise exist, which will go on increasing through life, and cannot but make a great difference to the manner in which life's work is done." If time allowed I would pursue this point further, and I will content myself by quoting other words of Dr. Gowers, and say with him: "Of two students with equal ability, character, and knowledge, of whom one knows shorthand and the other does not, it is certain that the one who knows shorthand will far exceed the other who does not. Whatever a student would do without it, he will certainly do much more, achieve a higher position, gain greater capacity, be more fitted for the work of after-life, and do that work better, if he uses shorthand."[1]

But for the student to secure these advantages it is essential that shorthand be learnt before medical studies begin. The attempt to learn it after study commences is more likely to be a hindrance than a help, although a student of ability and determination may succeed in acquiring it. When he is qualified, however, a man may

[1] The Use of Shorthand by the Student. Price 2d. London: Sir I. Pitman and Sons, 1, Amen-corner, E.C.

Digitized by Google

take it up with advantage, and the sooner the better. Many times have I wondered why some encouragement is not given by the ruling medical authorities to the preliminary study of shorthand. Twelve years ago, in the preface of a little book I published, I put in a plea for its inclusion in the optional subjects of the student's preliminary examination, and if the General Medical Council could see their way to adopt such a proposal they would, by bringing shorthand before the notice of the intending student, be conferring a lasting benefit upon him by placing in his hand a weapon with which he could more easily, more surely, and more thoroughly hew his path through the forest of subjects he has to traverse before he can receive his diploma or degree. And the advantages of a knowledge of shorthand will recur again and again in increasing ratio throughout the life of the now qualified practitioner. The chief, but by no means the only, use of shorthand to the medical practitioner is found in making notes of the cases he sees, and I would refer particularly to the advantages I have found from it in cases which have become the subject of subsequent legal investigation. At any moment a medical man may be called to the victim of some murderous attack, when the ability to at once take down what he hears and details of what he sees will not only be invaluable to himself and his reputation, but may guide the course of justice as to the guilt or innocence of accused prisoners. At post-mortem examinations, where he may be present on behalf of some individual or as the servant of the country, his shorthand writing will find scope for time-saving usefulness; whilst in the civil courts to which he may be summoned to testify by reason of professional relations with interested parties, his shorthand notes will ensure clearness and certainty to evidence which, if memory alone were trusted, would have a vagueness, soon to be converted by a clever cross-examiner into contradiction and unreliability. But the shorthand jottings—insignificant and unworthy as they seemed—will further the cause of justice and help the practitioner to preserve his credit and his reputation throughout his disagreeable ordeal in the witness-box. To the practitioner himself to take notes of his cases is one of the best guarantees of thoroughness of work, and, other things being equal, he who takes notes will do more justice both to himself and his patients than he who does not. Yet few general practitioners of medicine take notes, the high pressure at which his work has to be done, the scanty time at his disposal, and the cumbrous method of writing in general use being sufficient to deter all but the most energetic. Then volumes of often illegible and incomplete longhand notes soon accumulate and occupy much room, and if a system of abbreviation be adopted it is difficult for anyone but the writer himself to decipher the notes. Whilst the neat, compact phonography, lending itself so readily to the use of longhand headings, which point the reader to the spot he is seeking without having to traverse line after line of meandering scrawl, gives a pleasure and ease for after reference almost as remarkable as the time saved in the writing. In "The Use of Shorthand by the Practitioner"[2] the best methods of obtaining the fullest help from shorthand are described, and how the accumulating notes may be indexed so that any case may be at once referred to is set out with the clearest fulness.

The success of the Society of Medical Phonographers has been most gratifying from the medical as well as the phonographic point of view. Students of medicine are eligible for membership for the moderate subscription of 3*s.* 6*d.*, and both students and practitioners, learners and expert writers, will find in the lithographed publications and circulating magazines the society has already established agencies which cannot fail to be most helpful in their work. Dr. Neil, of Warneford Asylum, Oxford, is the secretary, and to him applications for information and membership should be addressed.

As a time-saver and sparer of tedious clerical work, then, shorthand comes to the busy practitioner as an invaluable boon. And it is to be remembered that the treatment of the bulk of the illnesses of the country is in the hands of the general practitioners, a minority—and I suspect a small one—of cases being seen by hospital physicians and surgeons and specialists. If the latter represent the head of the profession the general practitioners are the backbone. If the experience of only a half or even a quarter of this army of general practitioners could be placed on record who can estimate the benefits to medical science? There are grey-haired general practitioners whose judgments have been matured by self-derived lessons of which they alone have the secret; and when they die their memories are treasured and their loss deplored by patients grateful for benefits received. But too often all the documents relating to their life's work they leave behind are well-thumbed visiting lists, well-kept day books, and fat ledgers. Their perhaps unique knowledge and experience die with them. I take no credit for pressing these facts upon you. This yearly waste of priceless knowledge has been deplored before, and an attempt made to check it. In 1880 Sir George Humphry, from the presidential chair at the annual meeting of the British Medical Association, held at Cambridge, proposed his scheme for collective investigation. "One work," he said, "a work that especially appertains to the Association, the work of collective action, of the 'pull all together' of eight thousand members of the profession, I mean the work of cumulative observation or accumulated data, has been too little attempted, or if attempted has been productive of too little result. I am aware that anything on a large scale of this kind is a serious undertaking, a gigantic enterprise; and I feel it, therefore, to be worthy of this gigantic Association. It is, perhaps, the only work in which all or a large part of the members can really and fully participate, and to which each can contribute his mite. It is almost the only way in which questions relating to temperamental, climacteric, and topographical agencies upon disease and many others can be fully investigated and solved. To engage the members of the Association as participators in any division of such work would prove one of the most powerful inducements to the cultivation of observation and thought respecting the mass of facts which are passing, now too often unnoticed or unheeded, before their eyes, and would tend more than any other thing to deepen their interest in the science of medicine, and to impart the charm of wider usefulness to the daily routine of life."

These are weighty words and might have come from the lips of some advocate of the use of shorthand in medicine. Yet collective investigation is now never heard of. Stamped with the approval of Sir George Humphry and other eminent men, taken up by one of the most powerful and wealthy associations in the world, rejoicing in a title which was more than attractive, and received with acclamation by the profession, it has failed to realise expectations. For notwithstanding the all-powerful agencies which called it into existence and supported it, this attempt to collate, classify, and utilise the experience of the general practitioners of the country failed because when practitioners came to make their returns they had to rely not on facts, but impressions of facts, not upon accurately recorded data, but upon the shadows which flickered in their memories after the lapse of weeks, months, or years, aided by the daily business entries in their day books and ledgers. Laudable and ambitious as the collective investigation movement was, it failed because the foundation upon which alone it could rest did not exist.

But the words of Sir George Humphry have lost none of their wisdom or cogency by the lapse of years. The need is just as great to-day as when the weighty words came from the presidential chair of the British Medical Association at Cambridge. And I submit, with all humility, that the missing link in the grand chain of collective investigation can be supplied by shorthand. A few jottings at the bedside of the patient or in the surgery or consulting-room make an undying record of what actually was, and can be made in an incredibly short space of time with ease at the moment and confidence for reference in the future. With the aid of such record collective investigation would be a living actuality—a noble edifice, resting on its only possible basis, the immediate record of accurate observation. And valuable as would be the results of a general use of shorthand to each individual practitioner and his patients, they are not the most important or significant of those which the future may have in store for medical phonography; and in giving to the subject the first place on the agenda paper of your conference you are not merely encouraging the spread of shorthand on the one hand and forwarding the interests of doctors on the other, but you are promoting what are above all the objects of the profession to which I have the honour to belong—you are assisting in the diffusion of what cannot but tend to the advancement of medical knowledge and the health and well-being of the community at large.

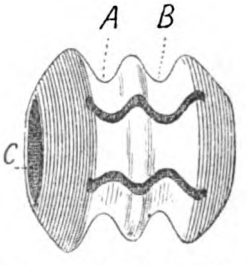
MEANS FOR EFFECTING INTESTINAL ANASTOMOSIS.



BY P. J. HAYES, F.R.C.S. EDIN., M.D., M.Ch. (Hon. Causâ) R.U.I.

SENIOR SURGEON TO THE MATER MISERICORDIÆ HOSPITAL, DUBLIN; PROFESSOR OF SURGERY, CATH. UNIVERSITY, DUBLIN.

THE interesting article on the employment of partially decalcified bone bobbins for facilitating intestinal anastomosis, published in THE LANCET of Aug. 31st last, by Mr. Allingham, led me to design a special form of bobbin, which, I venture to hope, will be found effective in cases of intestinal trouble necessitating either excision of a portion of the intestine and end-to-end junction, or the establishment of lateral communication between proximal and distal parts of the digestive tract. It is not at all my desire to criticise the several ingenious and valuable devices by which many well-known surgeons have overcome risks inseparable from operations of the kind just named. My sole object is to render the advantages belonging to each method easy of combination. It may be taken as granted that for the vast majority of intestinal operations a minimum expenditure of time ought to be linked with a maximum degree of assurance against danger of either leakage from or obstruction in the bowel. Probably most surgeons will also accept the view that the simpler the mode of suturing the less the operator will be hampered.

The bone or ivory bobbin which I have devised is of the form depicted in Fig. 1. It will be seen that the central

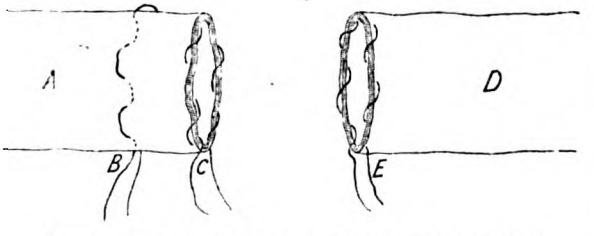


FIG. 1.

part has been longitudinally segmented by means of a fine saw, the number of sections being proportionate to the size of the bobbin. The ends of the bobbin up to, and a little beyond, the extremities of the section lines are decalcified. End-to-end union—say, after an enterectomy—is to be accomplished in the following manner. At the orifice of each

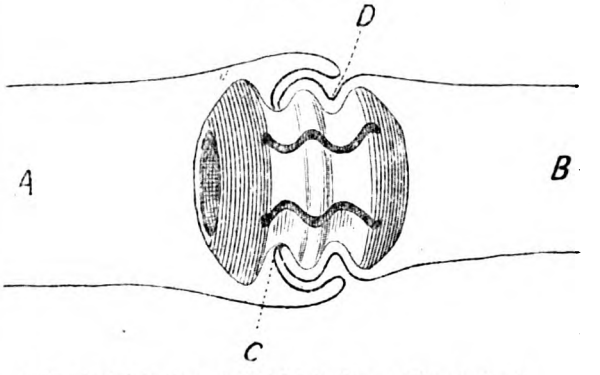

FIG. 2.

Intestine drawn on too large a scale. Shows proximal and distal portions of intestine prepared for end-to-end union. Marginal sutures traverse all layers of wall. Subserous purse-string only dips beneath peritoneal layer. A, Proximal intestine. B, Subserous purse-string suture. C, Marginal suture. D, Distal intestine. E, Marginal suture.

portion of intestine a marginal suture traversing all layers of the gut wall is to be inserted. On the proximal part of the intestine, about three-quarters of an inch above the marginal suture, a purse-string suture, implicating the serous coat only, is to be introduced (see Fig. 2). The ends of intestine, proximal and distal, are now to be drawn over the bobbin, until they correspond to the upper, or proximal, groove marked A in Fig. 1. Their marginal sutures are then to be drawn tight so as to make them fit well into it and securely tied. The final step consists in gently pushing up the bobbin and distal intestine, whilst careful downward traction is being made on the proximal intestine, until invagination from below upwards will have proved sufficient to bring the sub-serous purse string on the proximal intestine over the site of the bobbin-groove B (Fig. 1). This

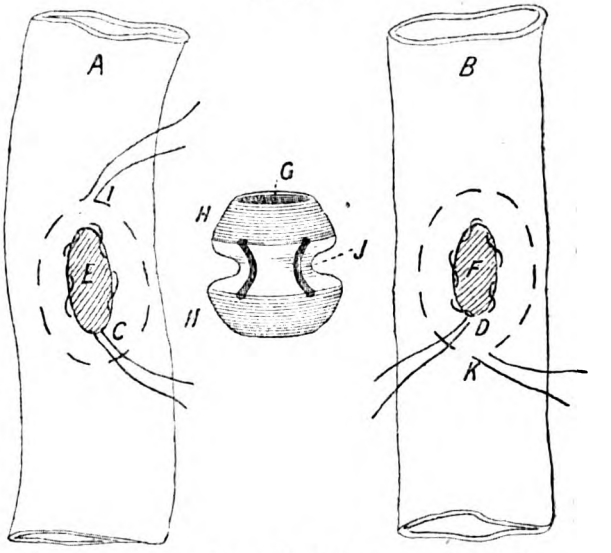

FIG. 3.

A, Proximal intestine. B, Distal intestine. C, The proximal groove where both marginal sutures secure the orifices of proximal and distal parts of intestine. D, Distal groove where subserous purse-string presses proximal intestine over invaginated distal.

purse-string, on being tied, will press the serous surfaces of the proximal and distal ends of intestine together, and by lightly compressing the distal portion over the corresponding groove of the bobbin afford absolute security against risk of slipping (see Fig. 3). Special features of the bobbin are—(1) its undecalcified condition where strength is required to bear pressure of ligature-like sutures; (2) its decalcified condition at the extremities, where solution takes place within a

FIG. 4.

A, Intestine. B, Intestine. C, Marginal sutures. D, Marginal sutures. E, Aperture to receive bobbin. F, Aperture to receive bobbin. G, Lumen of bobbin. H, Decalcified ends of bobbin. moderate period; and (3) the undecalcified segmented centre, which must fall as small fragments into the lumen of the intestine. Lateral anastomosis can be accomplished with the aid of the bobbin just described, but in some instances it will be found preferable to effect it in the following fashion. The surfaces to be united are marked off by two sutures (see Fig. 4), the inner suture being a marginal one for the border of the

Digitized by Google

operation wound—which may be made either before or after insertion of the sutures—the outer is to be a purse-string dipping beneath the serous tissue only. When proximal and distal parts of the intestine will have been thus provided with openings and sutures, a bobbin, which may be termed "single," to distinguish it from the form previously described, and to which the prefix "double" can be attached, is to be externally covered with thin "protective," and either end is to be inserted into one of the previously prepared intestinal apertures. Each marginal suture is then to be securely tied, and finally each purse-string is to be drawn tight and knotted. The marginal sutures will cause the edges of the openings to closely embrace the deep groove of the bobbin. The purse-strings will press the serous surfaces also well into the sulcus, rendering them corrugated and maintaining them in extremely close contact. The object to be effected by investing the outer surface of the bobbin with a layer of protective or other suitable membrane is to safeguard the groove against any escape of intestinal contents through the slots segmenting the undecalcified centre of the bobbin.

It will be seen that the sutures to be employed are of the simplest character and most easy of insertion. There is no need for any prolonged operation. In the employment of the double bobbin there is absolute security against any contamination of the peritoneum, and as the undecalcified parts, designed to withstand the pressure of ligature sutures, will be set free as small pieces when the bobbin ends become dissolved, there is freedom from all risk of impaction. In London Messrs. Krohne and Sesemann, of 8, Duke-street, Manchester-square, W., have prepared bobbins according to my instructions. In Dublin Messrs. Smith and Sheppard, of 124, Stephen's-green, are able to supply samples.

Dublin.

CLINICAL REMARKS ON CASES OF CHRONIC BRONCHITIS.[1]

By A. G. AULD, M.D.,

ASSISTANT PHYSICIAN AT THE GLASGOW ROYAL INFIRMARY.

THERE have been recently in these wards a goodly number of cases of chronic bronchitis, to several of which we may appropriately apply the more homely designation of "winter cough." They begin to appear in great numbers in the autumn of the year, more especially at the out-patient department, where, I should say, roughly speaking, they number at least one-third of all the cases. It is, therefore, the change of weather which brings this about. A vast number of bronchitic patients cannot afford to winter abroad and avail themselves of the "special" cures, and in the case of out-patients at the hospital a great many cannot even obtain that equable temperature indoors which is so essential under many conditions of the disease. Consequently, in our treatment of the latter class we are limited very much to the employment of drugs. Now, in any given case of chronic bronchitis which we are called upon to treat—and I am referring more particularly to treatment by drugs—various problems requiring solution present themselves. Few chronic diseases, indeed, exhibit such diversities in different subjects. Antecedent constitutional conditions are in great part responsible for this, though I do not go so far as to say that bronchitis is invariably grafted on some constitutional weakness or diathesis. The question of the origin of the affection is, however, far too wide for our consideration here. What I specially desire to bring before you is that each individual case demands its own special investigation and a line of treatment in accordance with the results of this investigation. We may be, some of us, unfortunately, too often in the habit of prescribing certain remedies somewhat indiscriminately, on the assumption that cases of chronic bronchitis are all very much alike. The method of "pinning our faith," as the saying is, to any particular drug or combination of drugs is conspicuously inept in this affection, for which, indeed, there are no specifics. It is a proceeding which is untrue to our art, and is sure to end in disappointment.

In illustration of these remarks let us look in the first place at two cases which are in many respects alike, though by no means entirely so. The first is a man thirty-nine years of age who has had winter cough for twelve years. This is unusual in so young a man and leads us to suspect that the subject of it must be of a scrofulous diathesis. In such, as is well known, the various mucous membranes of the body are unduly vulnerable, being especially liable to the catarrhal process. He is fairly well nourished, somewhat pale yet slightly cyanotic, and we find by a process of elimination that the lungs are the only organs in which we can definitely locate disease. His temperature is normal. On examining his chest we find from the hyper-resonance to percussion and otherwise considerable generalised emphysema, and auscultation reveals the presence of numerous crackling râles throughout both lungs. We do not detect many sibili or rhonchi, but from the extreme apices to the extreme bases these medium-sized, seemingly viscid râles are exceedingly abundant, so that this is a very severe case of the disease indeed, for the affection is deeply rooted. Also, it will be noticed that the râles are heard almost exclusively, if not exclusively, during inspiration, and chiefly towards the end of this act. Again, on listening, for instance, underneath the clavicles we find that the expiratory murmur is rough and somewhat bronchial in character. This, it may be remarked, is also, in conjunction with certain other phenomena, one of the earliest signs of phthisis. In either case it is due to the altered condition of the bronchial tubes. Normally, the bronchial tube which ramifies within the lung is a thin delicate cylinder whose elastic walls in their gentle recoil noiselessly propel forwards the air in expiration. Not so here; instead, the tube has become converted from congestion, &c., into what may be regarded as a rigid body on whose roughened and unyielding walls the air of expiration harshly plays.

I may, perhaps, in a manner digress here just to mention a peculiar, and, I believe, undescribed condition of the inflamed mucous membrane of the trachea and largest bronchi in certain severe cases. It is well known that post mortem longitudinal bands or ridges are often found, giving the hypertrophied membrane, more especially over its posterior tracheal surface, a ribbed appearance. These ledges are formed chiefly of a granulation-like tissue, but very frequently quite a large amount of elastic tissue is likewise present. But in one or two cases I have detected quite large nerves traversing this tissue. In the normal membrane it is extremely difficult, even with the highest powers of the microscope, to trace the nerve twigs. That comparatively large nerves, therefore, should be found in these ledge-like bands is a curious problem in pathology. Suffice it to say here that they would very well serve to explain the excessive irritation which the cough betrays in these cases.

The second case is that of a man thirty-five years of age who has had winter cough for five years. He says that he has frequently to inhale a sulphurous atmosphere. He is thin and pale, but presents no evidences of deficient aeration of blood. His temperature is sometimes in a slight degree above the normal. Physical examination reveals that his right lung is free from bronchitis, but the left lung throughout presents a condition exactly similar to what we found in the lungs of the first patient—that is to say, it is throughout the seat of numerous râles; but little emphysema, however, can be detected. The unilateral character of the disease in this case, and its extent, viewed in connexion with numerous other cases which I can recall, are by no means of good augury as to the ultimate issue. It is rather to be suspected that there is a special weakness in this particular lung which, if neglected, will show itself in other forms at no very distant date. At present, however, we only find the bronchitis. In both these patients expectoration is scanty and the cough is very troublesome, especially at night and in the early morning.

In treating these cases we have two indications clearly set before us. One is to relieve the symptoms—the distressing cough, the laboured breathing, and the uneasiness and tightness in the chest; and the other, to raise the quality of the patients' tissues so as to enable them to overcome the disease and resist its further invasion. To fulfil the first of these indications the patients have been taught to inhale the spray of ipecacuanha wine diluted with twice its bulk of water. This mixture is sprayed into the throat by the ordinary hand-ball apparatus morning and evening for about ten minutes, the patient being directed to spit out the liquid which accumulates in the mouth. The result of this treatment has been that the second patient has been greatly relieved. His expectoration is easy, he coughs but little, and he gets a good night's sleep. The first patient has also received benefit, but not so marked. Other drugs may be given in this manner to soften the mucus, but it is an interesting question how far improvement is due to the drug and how

[1] Delivered in the Glasgow Royal Infirmary on Nov. 29th, 1895.

Digitized by Google

far it may be due to the moisture. Dr. Wolfe, at my suggestion, gave the second patient the spray of hot water the last day or two, and the patient expressed himself just as much relieved as he did with the ipecacuanha. However, this may have been due to the previous good effect of the latter. Another process which may be advantageously combined with this is massage of the chest and back, with the use of a rubifacient such as the compound liniment of camphor. It will not suffice merely to rub with the liniment for a few moments over the surfaces. It must be a systematic and thorough massage, and so helpful and refreshing is this to the patient that many will on no account do without it. I do not see that we should be eternally vexing our souls as to the "how" and the "wherefore" of everything, and so I will not stop to discuss the possible manner in which this process does good. It is a grand thing to lighten the burden of a sufferer and enable him to proceed more cheerfully on his way, which is often weary enough. In regard to the second indication of which mention has been made—viz., the improvement of the patient's general condition—these cases would indicate the employment of cod-liver oil in large doses, which, in addition to its nutritive qualities, is also a valuable expectorant. By these various means, and with other circumstances favourable, many such cases can not only be relieved but permanently cured. With regard to the use of ipecacuanha there is a caution to be given, and that is that it is not a safe agent to use in cases wherein there is disease of the heart.

In the next place let us look at another case which presents very different features from those just considered. The patient is a man fifty years of age and has had winter cough for three years. His skin is of a somewhat dusky hue, but on examining his mucous membranes it is evident that he is somewhat anæmic. He has considerable emphysema, but his circulation is wonderfully good considering the state of his blood and the weakness of which he complains. Excepting his lungs, the organs generally appear to be in a healthy condition. Auscultation reveals numerous rhonchi and bubbling râles over both lungs. But the feature of the case is this, that without much difficulty he expectorates unusually large quantities of mucus. This, in an elderly man, has a very weakening effect and shows a low condition of vitality. It is not exactly what is known as pituitous catarrh or bronchorrhœa, but it is a condition approaching it. Herein we find the indications for treatment different from those we formerly considered, inasmuch as it is rather repression than encouragement which the expectoration demands. Encouragement, no doubt, to get rid of what accumulates, but repression of that abnormal secreting action of the mucous membrane of the air tubes. In order to effect this we may give by inhalation a spray of hot water lightly medicated with oil of turpentine or fir wood oil. In addition to this we give a mixture of perchloride of iron with some strychnine, which will act both as an astringent tonic and hæmatinic. This patient has for some days been subjected to this treatment, and already expresses himself as feeling much better. There are one or two other remedies which may be mentioned in connexion with this case. One is iodide of potassium, which in many cases of bronchitis acts in a rapid and marvellous manner, even when other means have failed. It is believed by some, however, that it should be withheld if there is a condition approaching to bronchorrhœa, although I have not fully tested this. The employment of a hydragogue cathartic is often attended with much relief in virtue of a vicarious or revulsive action. This may be more particularly indicated in plethoric subjects. Again, acute exacerbations are not infrequent, and in the case especially of obese persons such acute attacks may suddenly supervene on slight previous symptoms and may carry off the patient in forty-eight or even thirty-six hours. A smart purge at the outset of such attacks should not be omitted. It remains to be said that in cases such as these opium in all its forms should be avoided.

Now in these three patients we have found a bronchitis which is uncomplicated with evidences of disturbance in other organs. There has been, in two of them, the local complication of emphysema, but this is generally to be expected. But the most important, and certainly the gravest, result or complication of this disease is derangement of the circulation; and in order to study its effect on the heart and circulation generally we will in the last place briefly turn our attention to another case. This patient is a man fifty-three years of age, and we find that he was treated in the Glasgow Royal Infirmary over two years ago for bronchitis. The report of his case at the time referred to states that over both lungs, before and behind, numerous râles were heard, coarser in front and finer behind. The heart sounds were "booming" in character, but no murmur was present. The apex beat could not be definitely localised. Respiration was 40 per minute; the cough was bad, with yellow sputum; the pulse was 84. There was no indigestion; the bowels acted regularly; the urine was normal; and he left the hospital improved. At the present time there is not much new to note with regard to the râles, which remain pretty much as they were; but there is very marked general emphysema, so that his chest is somewhat barrel-shaped. As we looked at him, propped up in bed a few days since, you would have observed his anxious straining for breath, his labouring chest, the prominent veins in his neck and face imparting in their ramifications a dusky patchiness to the latter, and his earnest yet restless gaze. Although still propped up in bed, his breathing is now fairly calm; venous congestion about his face is still, however, apparent, while a more reposeful expression exists in his eyes. The reason for this change will shortly be mentioned. With regard to defective aeration of the blood it is necessary to remember that it produces two symptoms which are apt to lead the unwary astray. One is a reduction of the temperature, the other an enfeeblement of the pulse. This patient's temperature has for some time been frequently sub-normal, and his pulse until recently under 60. Therefore, in many cases of bronchitis the state of the pulse and temperature is not a safe guide as to the severity of the inflammation. Turning to the physical examination we find in the first place that there is much œdema of the skin of the trunk and legs. There is also some ascites. Then on listening over the bases of his lungs we make out fine moist crepitations, but these are not so marked as might have been expected. It shows that there is some œdema of the lungs as well. Examination of the liver shows some increase of dulness, which means that it is congested, while his urine contains a small quantity of albumin, which unmistakably points to some congestion in his kidneys. That congestion is present also in his stomach is shown by his distaste for food. In point of fact, we find that the venous circulation is impeded throughout all this man's body. With regard to the stomach, a year or two ago I happened to make some microscopical examinations of congested stomachs such as we find here and in certain conditions of Bright's disease, in the latter case due to poisons seeking elimination. It was really surprising to find the degree to which the capillaries which ramify between and amongst the gastric glands had become developed. In well-preserved stomachs they formed a plexus which ramified over the free extremities of the villi, and the extreme tenuity of their distended walls made one wonder how in an organ subject to so much disturbance hæmorrhages were not more frequent in such cases. The probability is that capillary hæmorrhages are really more common than is supposed, the only indication of which might be a temporary darkening of the fæces.

In order to find the explanation of the general venous congestion we turn to the heart and readily make out enlargement of the right ventricle. The apex beat is diffuse and displaced downwards and to the right, but the presence of emphysema prevents the mapping out of the ventricular border. No murmur can be detected, but the first sound has an impure or muffled character. On listening over the base reduplication of the second sound is heard, due, as is usually supposed, to the difference in the tension between the two sides of the heart. Before the patient was put under treatment the heart beats were irregular, weak, and slow, numbering under 60 in the minute. The failure of the heart in such cases as this is generally put down to the difficulty experienced by the right ventricle in driving the blood through the lungs, while the defective aeration of the blood likewise interferes with its nutrition. We note further, however, that age has a good deal to do with it. In the case of the second patient mentioned, aged thirty-nine, who has had bronchitis for twelve years, we found the heart to be acting well. But senility of the tissues causes rapid failure, which goes on to fatty degeneration, and this condition of the heart, together with the extensive emphysema leads us to consider whether there is not a more or less universal tendency in this case to a degenerative process.[2] So that the bronchitis may not, after all, have

[2] Emphysema, by A. G. Auld, THE LANCET, Dec. 2nd, 1893

Digitized by Google

to bear the brunt of being the sole cause of the mischief. Under all the manifestations of disease there are hidden agencies at work whose presence eludes the most vigilant. It is a fine thing, no doubt, to go around the wards and "spot" the cases, to use the expression one so frequently hears. In this connexion, perhaps, I may be allowed to mention an anecdote of the late Sir Andrew Clark. A year or two before his lamented death a lady went up from Glasgow to consult him. When the examination was over the patient said: "And what do you consider to be my disease, Sir Andrew?" The reply was: "Well, if I were a young man, I should certainly give your disease a name, but being an old man I prefer not to apply any name to it." There is a good deal of food for reflection in this. In reference to the treatment in this case it is incumbent on us to give as prompt relief as we can to the condition of the circulation. To this end we gave medium doses of digitalis, and for the condition of his lungs a stimulating expectorant is clearly indicated. Carbonate of ammonium in fairly large doses, together with the compound spirits of ether, was therefore used in conjunction with the digitalis, and we are pleased to find a marked improvement since this was begun. We endeavoured in this way to obtain diuresis, and the result has been that his urine has risen in quantity from 31 ounces on admission to 118 ounces to-day. With regard to carbonate of ammonium I may mention that it is sometimes very serviceable when given in large doses, even as much as ten grains, and glycerine is an excellent medium wherewith to administer it. Should, however, the time come when these remedies fail us, we may resort to the inhalation of oxygen, and should cyanosis become an urgent symptom venesection is often followed by much relief.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF GASTRO-INTESTINAL HÆMORRHAGE IN AN INFANT.

BY LOUIS E. STEVENSON, M.B. CAMB.

IN the columns of THE LANCET of April 22nd, 1893, I placed on record a case of this extremely fatal disease. A second case has recently come under my notice. The labour history of the mother is rather unusual and is briefly as follows. Liquor amnii drained away on Nov. 16th, 1894. The woman was assured by a neighbour that this was only the "womb slipping down," and I was not sent for. I happened to call on the Wednesday following, when I found the patient looking much smaller than one would expect at the end of gestation, and she complained to me that the waters had come away, but she had had no pain whatever. I wished to examine, fearing a mal-position, but the patient did not appreciate my anxiety. On the evening of Nov. 25th I was summoned, but found on my arrival that the child had been born one hour. I removed the placenta, which was extremely small, by expression. The child (female) was puny and emaciated-looking, there being apparently an almost entire absence of adipose tissue in her body and limbs; she had the appearance of being starved. The function of respiration was established with difficulty. The child was ordered to be wrapped in cotton wool and kept warm. Next day she breathed rather heavily, but on the following day took the breast eagerly and seemed to have improved. On the morning of the next day I found the child very ill, having passed a treacly motion of blood mixed with meconium. The skin was of a deep icteric tinge, more like the hue of true jaundice than that of the so-called icterus neonatorum. There was no bleeding from the umbilical cord. Later in the day a considerable amount of bright-red blood was vomited and several more dark-coloured motions were evacuated, the child dying at 2 A.M. the following morning.

Remarks.—There was no history of hæmophilia, though the child herself may have been a hæmophiliac. More probably, I think, this was one of those cases where visceral congestion follows difficulty in the establishment of respiration. Hæmorrhage would also be favoured by debility of the child and possibly by uterine compression before birth. The nutrition of a fœtus must depend, I suppose, on the relative size of the placenta, as it is hardly likely that partial compression of the cord for nine days could account for the extreme emaciation of the child when born. The mother, I may add, is a strong, stout, healthy woman. I could not elicit any history of syphilis in the family.

Temple Sowerby, Penrith.

SARCOMA OF THE OVARY IN A CHILD.

BY FREDERICK PAGE, M.D. EDIN., M.R.C.S. ENG.,
SURGEON AND JOINT LECTURER ON CLINICAL SURGERY, NEWCASTLE-ON-TYNE ROYAL INFIRMARY.

A GIRL aged six years with a large abdominal tumour was sent to me by Dr. Bishop of Wylam-on-Tyne for operation. The abdomen had been noticed to be gradually increasing in size for about four months, but, the child's general health continuing to be good, no anxiety was felt. On Nov. 2nd the abdomen was opened, and a solid tumour of the left ovary weighing three pounds and three-quarters removed. There were no adhesions, and only some two ounces of blood-stained fluid in the pelvis. On Nov. 25th the child returned to the country, having made an uninterrupted recovery. The tumour proved to be a fibro-sarcoma. Mr. Bland Sutton, in his work on Tumours, alludes to twelve cases of sarcoma of the ovary in children under fifteen years of age which have been operated upon since the year 1874. Seven of the children died from the operation. The youngest patient was three years and a half old; Dr. Cameron of Glasgow operated, and the case terminated fatally. The youngest patient who recovered was seven years old, and Dr. H. Croom was the operator. The case now reported would seem, therefore, to be that of the youngest child who has, so far, been successfully operated upon for sarcoma of the ovary.

SEACOMBE COTTAGE HOSPITAL.

A CASE OF OVARIOTOMY; RECOVERY.

(Under the care of Dr. BOUVERIE MCDONALD.)

THE patient was a woman aged forty-two years who had been operated on for ovarian tumour of the left side five years previously at the Hospital for Women, Liverpool. She complained of an abdominal swelling, free from pain, and in no way affecting the general health. Menstruation was irregular. The tumour was central and extended three inches above the umbilicus; it was smooth and fluctuating below, but somewhat lobulated and more solid above. A multilocular ovarian tumour was diagnosed and its removal decided upon. On June 4th, 1895, Dr. Bristow administered an anæsthetic, and with Dr. Craigmile's assistance Dr. McDonald proceeded to operate. The only difficulty met with was in the abdominal wall, the old cicatrix having made the respective layers dense and adherent. The lower portion of the tumour readily collapsed after puncturing with a Spencer Wells trocar, and the upper and more solid portion was easily drawn through the abdominal wound. A Staffordshire knot of Chinese silk was used for the pedicle, and the abdominal cavity was freely irrigated with boric acid solution. A Keith's glass tube was used in the lower part of the wound, which was closed by interrupted silk sutures.

Digitized by Google

The progress of the case was highly satisfactory. The temperature once reached 100° F. The tube was removed on the second day. All the stitches were taken out on the eighth day, and the patient was out of bed on the fourteenth day. By the twentieth day she was looking after some of the children in the hospital, and went out daily afterwards.

Remarks by Dr. MCDONALD.—"Should ovariotomy be undertaken by the ordinary general practitioner?" is a question that may meet with as many "ayes" as "nays." It is, however, generally accepted that the operation—not only on account of the recognised experience of the operator, but also for the safety of the patient—is best performed by a specialist. My own private views have endorsed those of many of my medical friends that ovariotomy may present so many difficulties unforeseen that it is undoubtedly wise to leave the operation in the hands of one who is almost daily brought face to face with every contingency which may arise. I am fully aware that many cases have been undertaken by general practitioners, and also that a fair proportion have ended satisfactorily. Nevertheless, I consider that the operation should not be undertaken lightly—merely for the sake of having done an ovariotomy—but every consideration should be well weighed before proceeding to operate. It may, therefore, be of some interest to any who, like myself, are associated with a small hospital—where an occasional ovarian tumour presents itself—to give a few rules which might guide one—as they guided me—in deciding upon the operation. Firstly, the patient's absolute consent should be obtained. No general practitioner has any right to force his own services, or in my opinion even persuade a patient to submit to his limited experience in this direction. In the case described above I only consented to operate at the urgent request of the patient. Next in importance is the preparation of the patient by attending to rest, daily evacuation of the bowels, and giving plain wholesome food for three or four days before the operation. Thirdly, the preparation of the room. In this case I had the room fumigated with sulphur on three occasions. The walls and floor were carefully washed. The operating-table and chairs were also thoroughly disinfected, and nothing else but the bed occupied the room. All the instruments were, through the kindness of Messrs. White and Wright of Liverpool, new, and lay in carbolic solution (1 in 20) for eighteen hours before the operation. Skilful nursing is a necessity; as regards day work I was well off with the ordinary staff, but a nurse accustomed to such cases was procured for night work. Need I add to these primary rules the necessary confidence in one's own power to complete the operation? Granted that all the above conditions are present, then I consider that a general practitioner is entitled to undertake the case. The correct diagnosis of ovarian tumour is not to be passed over lightly, and here again the great advantage of a specialist is all-important. Even the differential diagnosis is not always easy, and, having satisfied oneself of an ovarian origin, the questions arise: Are there adhesions? Is the tumour solid or fluid? Is it unilocular? &c. One word of warning may not be out of place. I know of some young practitioners who, having successfully undertaken *one* case of a special kind, immediately allude to details of the case as "their invariable custom," but after one successful ovariotomy let no man be puffed up with his own prowess—rather let him, should he be called upon to undertake a second case, study every detail with the same anxiety which he showed in his first attempt. My thanks are due to Miss Collins and Nurse Hughes for their constant care and attention, also to Dr. Craigmile for his assistance at the operation.

Medical Societies.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Abdominal Aneurysm.—Abdominal Suppuration.

A MEETING of this society was held on Dec. 12th, the President, Mr. CHARLES KING, being in the chair.

Dr. BEEVOR read an account of a case of Abdominal Aneurysm showing peculiar symptoms. The patient was admitted into the Great Northern Central Hospital under his care suffering from symptoms of pressure on the roots of the upper lumbar nerves on the left side. Thus on carefully comparing the sensation of each thigh it was noted that there were areas of comparative anæsthesia on the left; the left knee-jerk was also diminished on comparison. A certain amount of reflected pain was complained of over the left great trochanter, and on percussion over the spines of the first and second lumbar vertebræ tenderness was found. It was then observed that there was a small abdominal tumour on the left side of the spine, but from the other symptoms it was thought to be malignant character. In a short time this tumour increased in size, occupied a large area on the left side of the abdomen, and showed expansile pulsation. Soon after this increase began to be observed, one morning, while moving in bed, the patient was seen to fall back, his face became blanched, and he expired almost immediately. On post-mortem examination there was found to be an aneurysm of the abdominal aorta which had caused erosion of the bodies of the first and second lumbar vertebræ and which had penetrated the left psoas muscle, dissecting through the soft muscular structure, and turning it into a secondary aneurysmal cavity. The blood had then passed upwards, and, passing below the diaphragm, had escaped suddenly into the left pleural cavity; death had resulted as the consequence of this accident. Dr. Beevor remarked on the importance of observing with care apparently insignificant physical signs as a means to accurate diagnosis, and especially the comparison of one side of the body with the other in the case of any symptoms involving sensation or any other interference with the nervous system.—In the course of the subsequent discussion Dr. GALLOWAY remarked on the absence of signs of referred pain along the course of the lumbar nerves, which must have been pressed on during the progress of the aneurysm.—Mr. MOWER WHITE pointed out the fact that from the anatomical relations the aneurysm must have perforated the strong iliac fascia on gaining access to the psoas muscle, and inquired whether it was not possible that the aneurysm might have originated in either the first or second lumbar artery instead of in the aorta itself.—After remarks by Dr. GLOVER and Dr. MORISON, Dr. BEEVOR replied, and said that there was no evidence that the aneurysm had originated in either of the two positions mentioned as possible by Mr. Mower White.

Dr. THOMAS HAMILTON then described a case of Abdominal Suppuration. The patient, a man in late middle life, had long suffered from symptoms of chronic dyspepsia, with gradual loss of strength. After a long period of illness he developed a tumour in the left side of the abdomen, about the iliac region. This increased in size, with rise of temperature, and presented much difficulty in diagnosis. The patient was seen in consultation by several physicians and the opinions formed differed, some being in favour of the diagnosis of abdominal suppuration and others of malignant disease. At length, on being seen in consultation with Mr. Langton, it was decided to incise the mass with the idea of exploration. On incision the tumour proved to be an abscess in connexion with the descending colon, and on microscopic examination of the wall of the cavity there was found to be no evidence of malignant origin. While the abscess was being drained there appeared in the discharge a coil of sausage skin and a bristle about ¼ in. in length. Dr. Hamilton was of opinion that the abscess was associated with the presence of these foreign bodies as irritants. In spite of all efforts to prevent the spreading of the suppuration the abdominal wall became extensively involved and death resulted.—Dr. GLOVER, who had seen the case with Dr. Hamilton, remarked on the extraordinary manner in which the abscess had simulated a malignant growth, and stated that in the first instance he felt quite assured of the malignant origin of the obstruction that was produced.—Mr. CHARLES KING spoke of the case, and criticised Dr. Hamilton's supposition that the foreign bodies mentioned had been the immediate cause of the abscess. Mr. King was of opinion that it was more probable that there had been a fæcal accumulation, possibly around the foreign bodies, which had caused ulceration of the mucous membrane, with a resulting pericolic abscess.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

THE third meeting of this society was held on Dec. 12th, Dr. J. DRUMMOND, President, in the chair.

Digitized by Google

Dr. GOWANS exhibited a boy whose Elbow he had excised a year ago for Tuberculous Bone Disease following an injury. The joint and humerus were extensively involved, so that more bone than usual required removal. On recovery it was found that a flail-like arm was the result, and an attempt was made to remedy this by prolonged rest in plaster bandages, but without success. Four months ago the ends of the bones were cut down upon, and the radius and ulna were wired to the humerus, and the arm was put up in splints for six weeks. The wire was left in, for ankylosis was expected, but it could now be seen that every normal movement of the arm was easily performed, and the boy had so much power in it that he could lift heavy weights.

Dr. LIMONT showed a man thirty-six years of age who had a chancre in 1894. Two months after a secondary rash appeared. He was admitted to the infirmary on Nov. 22nd, 1895, when there were still evidences of recent syphilis in the stains of eruptions and adhesions of iritis. He had to be held up, for he could not stand. He could move his legs in bed, but had little power in them. Sensation was unaltered, his leg muscles wasted, and reflexes increased. After he was admitted he developed incontinence of fæces, in addition to his urinary difficulty. He had now been in the infirmary for three weeks, and taking iodide of potassium in 20-gr. doses. A marked improvement was evident, for he could stand alone and walk a little; his bladder trouble was abating, and the anal weakness was gone.—Dr. LIMONT showed a man thirty-six years of age whose early history was complicated, for a dual infection (glanders and syphilis) was possible. On Feb. 2nd, 1895, he had a chancre. This was followed by a secondary eruption which had left traces of a strongly suggestive character. That he had syphilis at this time was proved also by the fact that he infected his wife, who had an ordinary attack of syphilis. About the same time as he noticed the chancre he was bitten by a horse. The horse was suspected to be suffering from glanders and was injected by mallein. The injection was followed by glanders reaction, and on post-mortem examination evidences were found of glanders in the horse. The proofs of glanders in the patient were not so convincing. Towards the end of February he had large white and yellow patches in the throat, with fœtid breath. At the end of March a skin eruption appeared, described as resembling measles at first, and then like small-pox, for the spots had matter in them. He was sent to the Infectious Hospital as a case of suspected glanders, where he stayed thirteen weeks. About a month ago he began to complain of headache and became listless and apathetic. Two weeks ago he noticed some difficulty in walking; his left leg and left arm, and speech became affected. He was admitted to the infirmary on Dec. 7th, 1895. He was listless, and took little notice of anything, and wandered in his mind at night. His left face, arm, and leg were weak, and the knee-jerk increased. The only other discoverable sign was that his left pupil was dilated. He had improved since admission. Dr. Limont said that in his opinion the condition was due to syphilitic disease with thrombosis of the cerebral vessels.—Dr. G. MURRAY said he had seen this case in March. The patient then had a sore-throat with white patches, an offensive discharge from his nose, and a pustular skin eruption. The history of possible glanders infection was complete. Discharges from the throat and skin and penile sore were treated for glanders bacilli, but they were not found. Inoculation of guinea-pigs also proved negative.

Dr. DRUMMOND showed a man forty-five years of age who had Syphilis ten years ago. Fifteen months ago he had headaches and similar symptoms, from which he recovered three months later under large doses of iodide of potassium. He had now complete paralysis of his right seventh and sixth nerves and partial paralysis of the right hypoglossal. His left arm and leg were paralysed. There was no optic neuritis, which was commonly absent in pons tumours. Vomiting was infrequent, as is also usually the case. Though gummatous tumours in the pons were rare there could be little doubt that a gumma of the lower part of the pons was present in this case.—Dr. DRUMMOND showed a child aged six who when a baby had been treated for bronchitis with brandy and honey. When a year old she had half an ounce of port wine daily, and at the age of three was allowed to have beer to dinner in addition to the port wine. At odd times, too, she was supplied with gin. A year ago she began to suffer from morning sickness, with loss of appetite, wasting, and weakness. Soon after an attack of measles last Christmas her abdomen began to swell, and for the last three months has been very large. She has been twice tapped, but rapidly refilled. The liver dulness is considerably increased, and the liver can be felt to be large and hard. The spleen is enlarged and hard also.

Mr. PAGE showed a man thirty-seven years of age who was admitted to the infirmary with a large Aneurysm of the Right Popliteal Artery of four months' duration. There was a history of syphilis, and the patient had extensive aortic disease. His femoral artery was ligatured at the apex of Scarpa's triangle on Nov. 21st, 1895. The wound healed by first intention and the aneurysm was cured.

Mr. WILLIAMSON showed a woman forty-eight years of age from whom the Uterus with Multiple Fibroids had been removed (with specimen).—Mr. WILLIAMSON also showed a young woman from whom a large Tumour of the Clitoris had been removed (with specimen).

Dr. HUME showed a man with a Malignant Stricture of the Œsophagus on whom Gastrostomy by Franks' Method had been performed. There was no redness of the skin round the fistula, and the contents of the stomach very rarely escaped. He considered this the best operation for establishing a permanent gastric fistula.

Dr. HUME showed a man about fifty years of age who had had three attacks of Intestinal Obstruction. The first occurred eight years ago, the second two years ago, and the third during last autumn. After the last attack he did not recover his strength, slight abdominal distension remained, and a firm, tender nodule could be felt above the umbilicus in the right linea semilunaris. On opening his abdomen the cæcum was seen to be distended, and the transverse colon contracted. The ascending colon and hepatic flexure were buried in adhesions, but sufficient could be felt to give assurance that something was wrong there. The cæcum was opened, and a finger introduced discovered a tight stricture near the hepatic flexure of the colon. An opening was next made in a convenient part of the transverse colon, and an anastomosis made between this and the cæcum. The two openings were united by simple sutures without the aid of plates, or buttons, or bobbins, and the man's recovery had been uneventful. The operation was done three weeks ago, and already a marked improvement in his condition was apparent.

Dr. GOWANS showed a specimen of Cystic Adherent Ovaries and Enlarged, Thickened Tubes removed successfully by operation. The chief symptom complained of was intolerable pain.

Dr. DRUMMOND exhibited the Thoracic Contents removed from a man who died a month after the October meeting. The right lung contained a growth the size of an orange which had apparently commenced in a gland and invaded the right bronchus, which it completely occluded. The thoracic duct was also blocked by the growth, which accounted for the great and rapid emaciation. There was pronounced bronchiectasis; the bronchiectatic cavities were filled with pus. (There was no rise of temperature during life, a fact Dr. Drummond had never noted before in any similar case.) Microscopic specimens (exhibited) showed the growth to be a lympho-sarcoma.

Mr. PAGE showed a Gall-stone as large as a green walnut removed from a woman fifty-two years of age. There were four smaller stones in the gall-bladder; the large one he thought was impacted in the end of the cystic duct, though the patient had no jaundice.—Mr. PAGE exhibited a portion of the Pelvis and Intestines of a woman sixty-two years of age who died in the infirmary after an operation for the relief of intestinal obstruction. The patient was a chronic invalid, and five days before her admission was suddenly seized with acute symptoms of obstruction. During the operation a portion of intestine was drawn out of the sac and the obstruction relieved, but death followed in a few hours from shock. The specimen showed from the front part a projection like a walnut of the upper and inner part of the obturator membrane, and from the back a pouch of like size with a somewhat smaller neck, formed by the membrane below and bone above. The specimen was an excellent one of this rare variety of hernia.—Mr. PAGE showed a Hydronephrotic Kidney which he had removed from a man twenty-one years of age. For fifteen years the patient had suffered from symptoms attributed to renal calculus.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—So-called Mittelschmerz.—Viburnum Prunifolium.—A Rare Form of Abortion.

A MEETING of this society was held on Dec. 11th, Dr. A. BALLANTYNE, President, being in the chair.

Professor SIMPSON showed specimens of: 1. An Exomphalic Fœtus, sent from Shanghai. It was the child of a white person, and presented by the herniated mass. The delivery was difficult and was assisted by pulling down a limb. 2. Anencephalic Fœtus which had been accompanied by excess of liquor amnii. The mother's first child was also anencephalic, and the pregnancy ended prematurely at six months. There are two children alive, one is an idiot and the other is deficient intellectually. 3. Malformed Fœtus, where the left forearm had only one bone and the hand was articulated at an angle to it with four fingers present, but with absence of the thumb; the right forearm was also imperfect, but better developed, and on the hand there was a thumb, but only attached by a skin connexion.

Dr. FELKIN showed a new Safety Pin where, after the end of the pin was fixed in the head, it could only be released by pressure on a small and easily worked spring catch.

Dr. F. W. N. HAULTAIN showed a specimen of Hæmatoma of the Ovary removed from a patient aged twenty-two years who had suffered from a sudden onset of pain in the right side two years previously, and six weeks before the operation from severe pain in the left side. The appendages were removed to relieve the urgency of the symptoms. The right ovary was found to contain a granular cyst with a deposit, evidently the remains of a blood clot; the left showed a well-formed blood clot in a cavity, found microscopically to have the walls of a follicle.

Dr. HAULTAIN also showed a specimen of Hæmatosalpinx obtained from a patient who had died from mitral disease; she had suffered from severe pelvic pain three weeks before death.

Dr. J. W. BALLANTYNE showed: 1. Photographs of a Dicephalic Fœtus born in South Spain. There were two heads and necks, two incomplete thoraces, and a single heart and abdomen. He referred to the fact that James IV. had a double-headed boy at his court who lived to the age of thirty years and could sing in different parts with the two heads and in different languages. 2. Photograph of a case of Congenital Elephantiasis occurring at Rio, Brazil. The mother had suffered from five distinct traumatisms, and one was attended with lymphangitis. The infant was born with a hypertrophic right leg, and in the blood of this boy streptococci were easily demonstrated. The child improved greatly under the use of iodide of potassium and elastic pressure. The medical attendant explained the case by the passage of the streptococci through the placenta to the fœtus. He had seen nine other similar cases. 3. A photograph of a Spurious Hermaphrodite.

Dr. J. HALLIDAY CROOM read a paper on So-called Mittelschmerz, sometimes called a form of dysmenorrhœa. The pain occurred at mid-term in the intermenstrual period with exact regularity. The attack simulated all the symptoms of dysmenorrhœa, more or less severe, but without a discharge of a menstrual character. There were three manifestations of this ailment: (1) pain occurring at a regular intermenstrual period and with no external flow; (2) pain accompanied with severe flow of blood; and (3) pain with a clear discharge. There were three possible explanations: (1) that ovulation and menstruation might not occur together, if the ovary were thickened and ovulation occurred at mid-term pain would be experienced; (2) due to an endometritic condition; and (3) due to a swollen Fallopian tube, a hydrops tubæ, which reached its height at mid-term and expelled its contents through the vagina, this being accompanied by pain. In one case Dr. Croom had removed the appendages for this condition and found a hydrosalpinx; the pain disappeared after the operation, but menstruation continued.—Professor SIMPSON mentioned that this symptom occurred in many patients, and was rarely the prominent one present. It usually disappeared with the treatment necessary for the main disease.—Dr. MILNE MURRAY had seen many cases. One was compelled to go to bed for two days with the "middle pain." The pain was agonising in this patient, and examination showed some endometritis, but no tubal distension. She was best relieved by two-drachm doses of bromide of potassium. Another case occurred in a patient who had borne four children; each pregnancy had terminated a fortnight before term. There was good ground stated for the assumption that conception occurred in this patient after the violent pain had passed off

Dr. THEODORE SPENNAN read a paper on Viburnum Prunifolium and its value in the treatment of dysmenorrhœa, giving the results of a research to discover what was the real action of the drug, its active principle, and if this active principle had an action corresponding to that of the whole drug. Viburnum was first brought into use by a Dr. Thares, U.S.A., in 1866 his attention having been drawn to it by its use among the negro population and the great benefits ascribed to it. It has now been extolled by different authorities in dysmenorrhœa, menorrhagias of the menopause, habitual abortion, threatening abortion, after-pains, false pains, and in diarrhœa and dysentery. Botanically, it is a shrub which sometimes becomes tree-like, and in spring produces white clustering flowers; it grows most luxuriantly in the southern states of North America. The root bark is officinal in the United States pharmacopœia and is the only part from which preparations are made; it is rather brittle, has a weakly astringent, slightly bitter taste, and a musty valerian odour. In the chemical investigation he found it very difficult to separate an active principle, but had succeeded in obtaining a body in solution after processes calculated to remove all other substances except alkaloids. It was obtained in very small quantity, only about ½ per cent. of the drug; this has an action on the frog very similar to that of the whole drug. It also contains an organic acid similar to valerianic acid and a resin. The physiological experiments gave very marked results. On the rabbit, large hypodermic doses produced drowsiness and some motor weakness. When introduced into the jugular vein, a neutral or slightly alkaline extract free from alcohol or resin, a tracing showed considerable lowering of pressure, which soon tends to return towards normal as the drug is eliminated. In frogs a concentrated decoction produced in half an hour sluggishness of reflex, muscular weakness, drowsiness, and death. An alkaloidal solution by injection caused incoördination of movement and muscular weakness almost amounting to paralysis. The most marked effect is obtained by passing defibrinated blood containing the extract through a frog's heart. The ventricle stops in diastole and is greatly distended; the auricle may go on beating for a few seconds and also stops. If the blood is removed by gentle pressure and pure blood passed through it, it begins to contract once more; if the poisoned blood is again passed paralysis again results. The effect on man was obtained by experiments on himself. He took six capsules, each containing the equivalent of one drachm of the ordinary fluid extract, within thirty minutes. Pulse tracings were taken before and during the experiment. After the doses the pulse became slower and softer, and the tracing showed a slightly more marked dicrotic wave; there was slight frontal fulness, not amounting to headache. Even with these large doses there was absence of great discomfort, and this proves the absence of toxicity Others, however, have noticed in their patients headaches, disturbances of vision, and dryness of the mouth. The conclusions he drew from his research are, that there is probably some diminution of reflex irritability, a quieting effect on involuntary muscle, and possibly some lowering of blood pressure, which, even though small, might afford relief in congested conditions. Then there is the important effect of the viburnic (or valerianic) acid in neurotic and hysterical conditions. As compared with the use of opium in similar conditions it does not cause such marked constipation and has practically no toxic effect, while in many cases its effects quite equal those of opium. The preparations are: (1) an aqueous decoction, not pleasant; (2) tincture, 1 in 5, or, as in France, 1 in 1; (3) fluid extract made with alcohol and water, dose one half to one drachm, which can be given every hour and a half; (4) inspissated extract made from the last and given in pill form, but is not dependable unless made fresh; and (5) capsules. These are made by evaporating one drachm of a 1 in 1 fluid extract to ten minims at a low temperature or *in vacuo*, and enclosing in a capsule. These are easily taken, as the taste and unpleasant smell are easily masked and are the best form for administration. Dysmenorrhœa could be classified under three heads: (1) obstructive, with a spasmodic element; (2) nervous or spasmodic pure and simple; and (3) inflammatory or congestive. He was inclined to confine the use of viburnum to cases where there is a nervous, hysterical, or spasmodic element. It is possible that by slightly reducing the blood pressure it may relieve congestive conditions, but

Digitized by Google

these are better treated by other means.—Dr. CRAIG had used the liquid extract of viburnum extensively for threatened abortions, and knew of no drug that was more effective.—Professor SIMPSON had given it in threatened abortion, and with sufficient results to encourage its use.—Dr. HAULTAIN administered it in dysmenorrhœa and as a uterine sedative. On the cutting pains of the first stage of labour he had not seen any effect; for after-pains no drug gave such good results except opium.

Dr. HAULTAIN read a paper on a Rare Form of Abortion, and showed two specimens illustrating it. He described cases where the amnion with the ovum or its remains had been expelled as an entire sac, leaving the decidua behind. In one case under his notice the decidua was removed six weeks afterwards; it required to be torn off, the operation being attended with very free hæmorrhage. There had evidently been pre-existing disease and death of the embryo, causing the attachment of the amnion to be less secure and its expulsion from the resulting uterine irritation. These specimens showed death a considerable time before expulsion. The decidua might go on growing, and would form a carneous mole.—Dr. J. W. BALLANTYNE questioned the absorption of the fœtus in these cases, believing it was rather due to its non-development.—Professor SIMPSON said that sometimes a little portion of cord would be found and yet no fœtus; the cord showed that there had been a fœtus, but it had been absorbed. He attributed these cases to the special toughness of the amnion, which had permitted of its bursting its way through the other membranes and being expelled entire. The amnion was three times as tough as the chorion. The caul was almost always formed of amnion alone.

Reviews and Notices of Books.

Die specielle Tuberculose der Knochen und Gelenke auf Grund von Beobachtungen der Göttingen Klinik. I. Das Kniegelenk. Bearbeitet von Dr. F. KOENIG, Professor der Chirurgie, Director der Chirurgischen Klinik. Mit 42 Holzschnitten. Verlag von August Hirschwald. Berlin, 1896. (*On Tuberculosis of Bones and Joints; from Observations at the Göttingen Clinic. I. The Knee-joint.* By Dr. F. KOENIG, Professor of Surgery, Director of the Surgical Clinic. With 42 Wood-cuts. Berlin: A. Hirschwald. 1896.)

PROFESSOR KOENIG has for twenty years filled the important post of Director of the Surgical Clinic at Göttingen. Having during that time accumulated a very large experience in tuberculous disease of bones and joints, he has resolved to publish a series of monographs based on this experience. The first is just published and treats of tuberculous disease of the knee. It is prefaced by a very careful and elaborate statistical summary of 720 cases by Dr. Mertens and Dr. W. Koenig. Then follow chapters devoted to the consideration of the pathological anatomy, the clinical history, the prognosis, and the treatment of this form of disease. The volume is a most valuable treatise and a rich storehouse of material. It would be impossible in the space at our disposal to go over in detail the ground so ably traversed by Professor Koenig; but we may say that he is at variance with the late Bradshaw lecturer as to the constancy with which the bones of the knee are involved in cases of tuberculous disease of the joint, and he has found that in about half the cases the disease is a tuberculous synovitis, and in a nearly equal number a tuberculous osteitis. No one routine method of treatment is advocated, but wide views are taken. Rest and extension are recommended in the early stages, and particularly in children; to these are sometimes added injections of carbolic acid and iodoform. Where these measures fail to produce speedy improvement arthrectomy is practised in children and excision in adults. Stress is laid upon the importance of resorting to operation more promptly in adults than in children, where the so-called conservative measures do not avail. The next volume of the series will deal with tuberculous disease of the hip.

Atlas des gesunden und kranken Nervensystems, nebst Grundriss der Anatomie, Pathologie, und Therapie desselben. Von Dr. CHRISTFRIED JAKOB. Mit einem Vorwort von Professor Dr. AD. v. STRÜMPELL. München: Verlag von J. F. Lehmann. 1895. Preis M.16. (*Atlas of the Nervous System in Health and Disease, with Outline of its Anatomy, Pathology, and Treatment.* By Dr. C. JAKOB. With a Preface by Professor AD. v. STRÜMPELL. Munich: J. F. Lehmann. 1895. Price 10*s.*)

THIS forms one of a series of hand-atlases which are in course of publication by the firm of J. F. Lehmann in Munich. Several volumes have already appeared, including two on Obstetrics by Dr. Schaeffer, who also edits one on Gynæcology; one on Skin Diseases, by Dr. Kopp; one on Ophthalmoscopy, by Dr. Haab; and one on Fractures and Dislocations, by Professor Helferich. The Atlas before us contains no fewer than seventy-eight plates, several of which include more than one figure. In the first place, a series is devoted to the morphology of the central nervous system, in which are found anatomical drawings and reproductions of photographs of the brain and spinal cord. Next comes a series (mainly diagrammatic) to illustrate the development and structure of the nervous system. An original feature in this part is a collection of twenty-one plates to illustrate the appearances seen on section of the brain from the frontal lobe in series backwards to the medulla. By a lavish use of colour the distinctive structures are made apparent. In a fourth section are illustrations of the general pathological anatomy of the nervous system, and, in a fifth, of the special pathology of the spinal cord and nerves. Appended to the Atlas is a concise account of the subjects occupying about 200 pages. Altogether the Atlas is well planned and executed, and its use should prove of distinct advantage to the neurological student, who will find in it a safe guide through the anatomical mazes of the nervous system.

Diseases of the Spinal Cord. By BYROM BRAMWELL, M.D. F.R.C.P. Edin. Third Edition. Edinburgh: W. F. Clay. 1895.

FEW words are needed to direct attention to the appearance of a new edition of Dr. Byrom Bramwell's interesting volume. Its author has the gift of lucidity in teaching, is fully aware of the advantages of illustrations in explaining textual descriptions and ding in their right interpretation, whilst he has, moreover, in such a subject as diseases of the spinal cord one which to an unusual degree demands such systematic and illustrative treatment. The subject is dealt with in the form of lectures, which has enabled the author to emphasise important facts and to speak with greater freedom than is customary in a purely formal treatise. After some general remarks on the anatomical, physiological, and pathological bearings of the subject, he opens his description of diseases of the cord with acute anterior poliomyelitis, departing from the usual order in considering its morbid anatomy before dealing with its clinical features. This topic leads naturally to progressive muscular atrophy, although he is careful to point out that the latter condition is one which is often associated with, and dependent on, primary sclerosis in the adjacent pyramidal tract. The distinctions between this amyotrophic lateral sclerosis and the form of chronic anterior poliomyelitis to which the clinical term "progressive muscular atrophy" is alone applicable are clearly set forth. From these topics he diverges to speak of the muscular dystrophies, of which pseudo-hypertrophic paralysis is the most striking example. The changes described in the spinal cord in this affection are hardly adequate to account for the muscular defect, and, as is pointed out, the disease is now generally regarded as a primarily myopathic affection. This chapter is illustrated by a number of well-executed

Digitized by Google

portraits. Locomotor ataxia occupies several lectures, and its remarkably varied clinical and pathological history is well narrated. The rarer conditions of Friedreich's ataxia, ataxic paraplegia, and syringomyelia receive considerable attention, and are deserving of careful study. In particular we would draw attention to the very careful and detailed analysis of the symptoms of syringomyelia, especially as regards its differential diagnosis from the numerous conditions that simulate it. Acute myelitis, chronic myelitis, and acute ascending paralysis are next discussed, and are followed by the subject of multiple cerebro-spinal sclerosis. Here again, in regard to differential diagnosis, Dr. Bramwell is full and explicit. His remarks on this head should prove of much service, especially those made in respect to the differentiation of disseminated sclerosis from general paralysis of the insane and from hysteria. Meningeal affections, tumours of the cord and membranes, concussion of the spine and traumatic lesions, with especial reference to "railway spine," complete a volume which has the merit of being readable and instructive, accurate without being too recondite, and above all practically helpful as a guide in the differentiation and treatment of spinal cord affections. Opportunity has evidently been taken to subject the work to careful revision, and its indefatigable author may be assured that his book is one which will be of service to many a practitioner who is unable to devote the time necessary to master more voluminous treatises of neurological science.

DIARIES.

MESSRS. BURROUGHS, WELLCOME, AND CO., Snow-hill-buildings, London, E.C., have earned the thanks of many busy practitioners by the publication of their *A B C Medical Diary and Visiting List*, which is so well and so favourably known as hardly to require detailed recommendation. The volume for 1896 is of a size very convenient for the pocket, and is strongly bound in blue cloth, gilt-lettered, with red edges, and a pencil holder at the back. The diary portion, which occupies about half the book, gives two pages (one opening) to each week of the year and is conveniently ruled for the insertion of patients' names, cash entries, and other memoranda. The special feature of the work, which distinguishes it from other publications of the same class and renders it of utility to prescribers, is a copious list of all the most recent additions to materia medica, together with a description of their actions and uses. Messrs. Burroughs, Wellcome, and Co. announce that they send a copy of this diary free of charge to every medical man in Great Britain, India, and Australia, and they invite hints and suggestions for incorporation in the issue for 1897.

MESSRS. CASSELL AND CO., La Belle Sauvage Yard, Ludgate-hill, send us *Letts's Medical Diary* for 1896 in various bindings, either red or maroon morocco, with a flap, inside pockets, and gilt edges, or in cloth with marbled edges. Each four pages (two openings) are ruled and headed to suit each week of the year. This diary is a long-established favourite.

MESSRS. HAZELL, WATSON, AND VINEY, 52, Long-acre, W.C., and 1, Creed-lane, E.C., are the publishers of *Smith's Physicians' and Surgeons' Visiting List* for 1896, which is now in its fiftieth year of issue and is well known to medical men. It may be had either strongly bound in morocco with pockets inside the cover, or of less thickness bound in cloth. The same firm are now bringing out *Hazell's Physicians' and Surgeons' Visiting List* for 1896, which is about the same size as the thinner form of Smith's List, but has the distinguishing feature that each alternate page, ruled with the days of the week and month, is less than half the full width. This arrangement has the advantage that it enables the visits of one month to be seen in one opening at a glance, and obviates the necessity for writing the names each week.

MESSRS. WILLIAM COLLINS, SONS, AND CO. (London and Glasgow) have a large variety of diaries for 1896, the largest being the *Scribblin; Diary*, interleaved with blotting paper, of large foolscap size, ruled for three days on each page, and the smallest being the *Bijou*, also ruled for three days on each page, and of dimensions suitable for the waistcoat pocket. The smaller sizes are handsomely bound in morocco.

The British and Colonial Druggists' Diary, 42, Bishopsgate Without, E.C., is now in its eleventh year of issue, and is a substantial volume of quarto size, interleaved with blotting paper, and ruled to show one week on each page. The introductory and concluding portions contain a large amount of miscellaneous information useful to pharmaceutists and prescribers, lists of the London hospitals, with the hours of attendance, and (which we hope will be omitted next year) lists of "general and specialist" physicians and surgeons in London and the provincial towns.

New Inventions.

A VACCINATION SHIELD.

IN order to avoid the irritating and injurious friction and pressure of the clothing at the site of vaccination, I have devised a shield which consists of a well-padded wire ring, bent to suit the contour of an infant's arm, and having its aperture filled by an open net-work of fine wire. There are no constricting tapes, and the plan of fixing the shield by means of adhesive plaster (preferably the American rubber plaster) renders any shifting of position impossible. In applying the shield, if care be taken that the strips of plaster do not overlap at their ends, there can be no constriction of the arm such as occurs when tapes are employed. The Chemists' Association, Limited, Curtain-road, E.C., manufactures the shield and has the wholesale agency for it.

Upper Tooting, S.W. EDWIN SMITH, M.B. Lond.

THE "BLUE BUOY" SWIMMING BELT.

MOST persons who have travelled by sea are familiar with the ordinary life-belt, consisting of slabs of cork connected by cords or fine canvas. Under the name of the "Blue Buoy" swimming belt Mr. J. E. Holdsworth, of 19, Golden-square, London, W., has brought out a similar article for the use of those who are learning to swim, the slabs of cork being replaced by japanned metallic cylinders about two inches in diameter. As each belt contains nine of these, conveniently fastened together by tapes, six of them being seven inches long and three of them ten inches long, its supporting effect in the water is sufficient to give confidence to the most timid novice, and when a certain amount of proficiency is attained the buoyancy of the belt may be reduced at will by the removal of some of the cylinders. The wearing of such a belt would probably enable bathing to be indulged in by anybody with safety, either in the sea or in fresh water.

FOREIGN UNIVERSITY INTELLIGENCE.—The list of successful candidates for the M.D. Degree of the University of Brussels was published on Tuesday, Dec. 10th. It contains the names of the following British practitioners:—Francis Howard Humphris, M.R.C.S. Eng. and L.R.C.P. Lond.; Charles Baring Langton, M.R.C.S. Eng. and L.R.C.P. Lond.; William Egmont Kirby, L.S A. Lond.; and Miss Harrison, L.R.C.P. and S. Edin. Mr. Humphris and Mr. Langton have both won their diplomas "with distinction."

THE LANCET.

LONDON: SATURDAY, DECEMBER 28, 1895.

THE ANNUS MEDICUS 1895.

Medicine.

THE study of the nature and causes of the specific infective disorders continues to occupy the chief place in medical research. The general acceptance of the fact that such diseases are due to the invasion of the body by microbic organisms is accountable for this, whilst the dependent subject of immunity, natural and acquired, is being profoundly investigated. The value of vaccination as a prophylactic for small-pox has been widely confirmed by the experiences of many parts of this country during the past few years, as recorded in the health officers' reports; and the long-expected Report of the Royal Commission on Vaccination, which has, moreover, to deal with many other aspects of the question, will, it may be hoped, shortly re-affirm this cardinal point. Meanwhile, science has advanced the subject of protective inoculations beyond the limits of providing immunity from possible attack, and in the discovery of antitoxins has opened up a line of treatment of the actual disease which may prove to constitute the greatest advance of the century. Throughout the year the results of the application of serum therapeutics to diphtheria have been steadily accumulating in all quarters of the globe, as the discussion on the subject at the annual meeting of the British Medical Association showed. In London the trials have been made on a large scale in the fever hospitals, and in due course we may hope to be furnished with a body of facts which will go far to determine the future position of this new therapeutic resource. The basis of the antitoxin treatment being the correct recognition of the true cause of the infective disease itself, there has necessarily been applied on a large scale what may be termed the bacteriological test for diphtheria; and the results of this method of study of the disease are tending to show that in a certain proportion of cases recognised clinically as diphtheria the Klebs-Löffler bacillus does not occur, whilst in a still larger number this organism co-exists with other pathogenic forms. It has also been proved that the bacillus in question may persist for a long period in the throat after all manifestations of its presence have passed, and that it may even occur without giving rise to any such manifestations at all. It is clear that in this disease alone there still remains much to be explained before its precise pathological history can be written. This is especially true in regard to the relationship it bears to other forms of epidemic sore throat and to the conditions amidst which the disease arises. Another infective disease in which an antitoxin has been discovered and practically applied is tetanus, but its comparative rarity perhaps accounts for the work upon it in this direction having awakened less widespread interest than the question of diphtheria. Nor can it be affirmed that the even older attempt to introduce a like method in the common affection, acute pneumonia, has been at all widely taken up, although the study of pneumococcus infections has been more and more extended and formed the subject of an important communication by Dr. WASHBOURN to the Pathological Society. The subject of pneumonia was also very fully discussed at the meeting of the British Medical Association, the debate being opened by Dr. DOUGLAS POWELL.

The etiology of enteric fever has continued to be the subject of inquiry by sanitarians, but no new facts as to the nature of the disease have been gained. The possibility, amounting almost to probability, of the transmission of the typhoid fever germ through shell-fish used as food has led to the undertaking of an inquiry on the question by the medical department of the Local Government Board.

The interesting discovery by LAVERAN of the malarial parasite continues to receive confirmatory evidence in various quarters. In this country Dr. PATRICK MANSON and Dr. THIN have made important and practical communications on the subject. It is true that another interpretation has been put upon the appearances presented by the blood in malaria by a worker in India, although the evidence must be strong to shake the conclusions which have been gradually built up by competent experts.

The discovery by PFEIFFER of protozoal organisms in variolous and vaccinal vesicles seems not unlikely to share the fate of the cancer-organisms, which, after a brief but not inglorious existence, have been almost wholly explained away. The fact, no doubt is that unless a disease organism can be cultivated outside the body it is rash to conclude in its specific properties from microscopical characters alone; and, unfortunately, no method has yet been discovered whereby the amœba-like masses regarded as parasitic in blood or cells can be so cultivated and observed apart from the tissues in which they are detected by high microscopical powers. Indeed, as regards vaccinia and variola, the evidence of other observers, as COPEMAN and KLEIN, points rather to a bacterial than a protozoal agent.

The evidence taken by the Tuberculosis Commission, and the general tenour of its report as to the transmissibility of the disease by the consumption of the flesh or milk of infected animals, confirm the opinions arrived at by similar inquiries on the Continent; but whilst the knowledge of tuberculous diseases is widening, the proofs of the direct transmission of the virus by contagion are not yet firmly established. The foundation of a prize by Dr. HERMANN WEBER, to be awarded triennially for work on this subject, is therefore an earnest of continued research upon it.

That rheumatic fever may rank among infective disorders has long been a matter of speculation; so far as it is capable of support from epidemiological considerations the admirable Milroy Lectures of Dr. NEWSHOLME supplied the required data.

The Congress of Medicine held in India at the close of last year was the means of bringing to notice many important questions in epidemiology, whilst the literature of this branch of medicine has been enriched by the completion of Dr. CREIGHTON'S History of Epidemics in Britain, and the reproduction by the Epidemiological Society of

London of BOGHURST'S "Loimographia," a description of the Great Plague of London by a medical eye-witness.

In respect to other diseases than the specific infectious class, contributions, both clinical and pathological, have been numerous and important. In this country alone may be mentioned the writings of FRASER, BALFOUR, CATON, EWART, and OLIVER on heart disease; of MARCET, FOXWELL, S. WEST, and POWELL on respiratory affections; and of GOWERS, BEEVOR, and TAYLOR on nervous diseases, the last named opening up new ground in his description of change in the spinal cord in pernicious anæmia. Dr. W. HUNTER, by the publication of his experimental researches in Toluylenediamin, affords fresh evidence in favour of his views on the pathology of pernicious anæmia, a disease in which the prescription of bone-marrow has apparently met with some success. Indeed, the gradual introduction of organic extracts in the treatment of affections of glandular organs has become a feature of modern therapeutics, since the striking efficacy of thyroid extract in myxœdema has been established. In his Gulstonian Lectures Dr. ROLLESTON gave a full description of the pathology of the suprarenal bodies, whilst the address of Professor SCHÄFER at the British Medical Association threw fresh light on their physiology, a subject further worked out by Dr. G. OLIVER. The influence of massage on the circulation has been experimentally studied by LAUDER BRUNTON and TUNNICLIFFE, and the application of this knowledge to the treatment of so apparently a hopeless condition as atheroma was happily set forth in an address by the former, published in these columns. Amongst purely pathological works. it must suffice to mention that the present year has seen the publication of new editions of such standard books as those of ZIEGLER and COATS, the appearance of an English edition of WEICHSELBAUM'S "Manual," and the completion of Professor HAMILTON'S work on Pathology. Of works on Medicine several new editions of familiar text-books have appeared, and such new and extensive treatises as the "Handbook" of PENZOLDT and STINTZING, the "Traité de Médecine" of BROUARDEL, GILBERT, and GIRODE, and the first volumes of the singularly styled cyclopædia, "The Twentieth Century Practice of Medicine."

Surgery.

During the year which is closing distinct progress has been made in many branches of surgery, though no discovery of striking importance has occurred. In the surgery of the abdomen the method to be employed in intestinal anastomosis and kindred operations has been a subject much discussed. Murphy's button is undoubtedly the easiest and the simplest in application, and it is claimed for it that no subsequent contraction occurs at the point of union. Numerous cases have been recorded where the result has been everything that could be desired, but, as might be expected, the button has its opponents, and two main objections are brought against it, the one that perforation is likely to occur where the two halves of the button touch, and the other that the button is very liable to be retained for a lengthy period, or even permanently. These objections, in part at least, seem founded on theoretical considerations, for the cases quoted in Professor MURPHY'S paper, which includes all known cases operated on with the button, are sufficient to show that the button is capable of giving very good results. Many other devices are employed for the same purposes, and perhaps the latest is Mr. ALLINGHAM'S bone bobbin for end-to-end intestinal anastomosis.

We have recorded a successful use of the button in what may be called cholecystenterotomy, though the cavity which was opened into the bowel proved to be a dilated common bile-duct, and not the gall-bladder. The Czerny-Lembert suture is still much employed, and Mr. HERBERT PAGE has recorded two successful cases in which fæcal fistulæ were treated by resection of the bowel and this form of suture was used. Pyloroplasty, as the Heinke-Mikulicz operation is usually termed, is being more frequently performed. A very satisfactory instance of its employment by Mr. MORISON of Newcastle is recorded in THE LANCET. The operation may be briefly described as longitudinal section and transverse suture of fibrous stenosis of the pylorus. It has also recently been employed for simple stricture of the intestine, and Mr. MAYO ROBSON advocates the use of his bone-bobbin as an adjunct to the operation; he has recorded a case where he successfully employed it for a fæcal fistula of the small intestine with narrowing of the bowel beyond. Appendicitis still claims much surgical attention, though the general tendency is now towards less frequent operations. We were able at the beginning of the year to give a report of an address on this subject by Professor WHITE of Philadelphia, whose careful account of the anatomy and pathology of the appendix helps greatly to elucidate many of the important problems connected with this structure. Professor OGSTON of Aberdeen has endeavoured to devise a method of dilating a fibrous stricture of the pylorus without operation. He considered that if a solid body could be made to pass at intervals through the narrowed opening the stricture might be dilated, or at least its contraction might be delayed. With this intent he administered by the mouth small spheres of gutta-percha, hoping that the muscular contraction of the stomach would suffice to force them through the pylorus. The spheres were given immediately after breakfast and were of such a size as just to pass through the pylorus. They were given at intervals of five days and were gradually increased in size. Though they were employed in four cases, yet only one of these can be said to have given the method a fair trial. No opinion can be expressed as to the value of this method until more extended observations have been made. Mr. CARTHEW DAVEY of Liverpool records the death of a patient on whom pylorectomy for carcinoma was performed by Mr. RAWDON five years previously; for three years and a half of this time he remained in perfect health. Such a lengthy period of freedom from recurrence is unique. Perforations of the hollow abdominal viscera with extravasation of their contents into the peritoneal cavity are now readily treated by laparotomy and suture, instead of being left to the very faint hope afforded by the administration of opium. We have recorded a case of perforation of the gall-bladder after ulceration in a case of typhoid fever. In another case, where an ulcer of the stomach had perforated and had been closed by suture, a second ulcer gave way two days later and rapidly proved fatal.

Digitized by Google

Mr. MARMADUKE SHEILD in a paper on duodenal ulcer has pointed out how very obscure the symptoms of this lesion are, and he has shown by two cases that it may be missed, if not especially looked for, even after laparotomy. A case of dilatation of the common bile-duct, very similar to the one to which we have referred above, and simulating a distended gall-bladder, was described by Mr. EDGEWORTH of Bristol; the condition is so rare that it is well worthy of description. Intestinal obstruction caused by the impaction of a large gall-stone is recorded by Mr. EVERLEY TAYLOR of Scarborough; laparotomy and enterotomy were performed and the stone removed; the patient recovered; the stone measured four and a half inches in circumference, and was two inches long Mr. BLAND SUTTON recorded a series of three successful splenectomies all occurring within six weeks. Splenectomy is now much more frequently performed than formerly, and the results are very satisfactory except when the operation is done for leucocythæmia, and then recovery is, we believe, unknown. Deputy-Inspector-General REID has described an interesting case of double popliteal aneurysm; the larger aneurysm, that of the left leg, was treated by Surgeon TOWNSEND by intermittent pressure with a Carte's tourniquet, and by the end of five weeks the cure was complete, a large, hard, non-pulsating mass remaining in the popliteal space. The aneurysm on the right side was treated by "Reid's method." Potassium iodide was given in order to increase the coagulability of the blood, and Carte's tourniquet was occasionally applied to the femoral artery to open up the collateral circulation. Then the elastic bandage was applied in the usual manner, except that a protecting gutta-percha pad was placed over the aneurysm to ward off any direct pressure. At the end of an hour Carte's tourniquet was put on and the constrictor removed. The tourniquet was slackened after five hours, and a faint pulsation was felt, which, however, ceased at the end of five days. On a comparison of the two results, it was seen that the aneurysm on the left limb, treated by slow pressure, though cured, still formed a hard, unyielding lump in the popliteal space, causing a good deal of discomfort to the patient and interference with the use of the limb. In the aneurysm in the right leg, treated by Reid's method, only a small mass was left on the floor of the popliteal space; it could hardly be felt and caused no inconvenience. Moreover, in the limb treated by the slow method no pulsation could be felt in the femoral below the origin of the profunda; while in the other limb the femoral pulsation was obvious in the lower part of Hunter's canal, but this difference in the length of artery occluded must not be taken as a usual difference in the results of the two methods Another case of aneurysm possessing considerable interest was under the care of Brigade-Surgeon-Lieutenant-Colonel STEVENSON. It was an abdominal aneurysm, and on laparotomy being performed it was found that the artery affected was the superior mesenteric, and that it was not possible to apply a ligature on the proximal side of the sac. It was determined to treat it by the introduction of a length of coiled steel wire; two yards were introduced through a fine cannula. Free hæmorrhage occurred at the time, and further severe hæmorrhage came on the same evening. The patient died the next afternoon from syncope. In this case the laparotomy was undoubtedly indicated, but the introduction of coiled wire into the sac of an aneurysm has been tried so often that it may now be put aside as a useless method of treatment. Even had a cure resulted, it is very doubtful whether the small intestine could have survived such an interference with its blood-supply. The transperitoneal operation for ligature of the iliac arteries for aneurysm has been performed twice on the same patient by Mr. MAKINS with an excellent result. This method obviates any interference with the sac wall, a point of much importance when the peritoneum is firmly attached to the wall of the aneurysm. There is a growing tendency to open the abdomen elsewhere than through the linea alba, for it has been shown that better union and less likelihood of a hernia result when the incisions are not made through ligamentous structures.

We were able to give in the columns of THE LANCET a translation of an eloquent address by Professor MUSSI of Bologna on the Surgery of Intracranial Abscess, in which he pointed out that, though our powers of diagnosis of cerebral abscess were not great, yet that exploratory trephining in doubtful cases gave most excellent results. The treatment of microcephalic idiocy by removal of portions of the cranial wall has hardly met with the success which was at first anticipated and which has been attained in a few cases. The explanation of this is to be found in the fact that two entirely distinct classes of cases have been included under the one name; the more numerous class contains the cases in which the skull is small because the brain has ceased to grow, and Sir GEORGE HUMPHRY has shown that of nineteen cases of which he gives details all belong to this class. There are, however, a few cases to be met with in which the early obliteration of the sutures has prevented the growth of what is really a normal brain; in these benefit may reasonably be expected from removal of bone, but such cases are very rare indeed. It is, therefore, obvious that indiscriminate operation in cases of microcephalic idiocy can only be productive of many unfortunate results.

It is now generally recognised that death in most cases of tuberculous meningitis is the result of dilatation of the ventricles, which is caused by blocking of the foramen of Magendie by the exuded lymph on the base of the brain. The former surgical procedure of tapping the ventricles did no permanent good, as the fluid rapidly re-collected. Better results are now obtained by *draining* the ventricles after puncture, for by this method a permanent outlet is provided from the cavity of the ventricles to the subdural space. A good example of this method in which Dr. KERR of Bradford operated was reported in the columns of THE LANCET It is not long since it was usual to allow a bone to remain dislocated if it could not be returned by manipulation or traction, but now many surgeons cut down on the joint, divide any structure which prevents reduction, and return the bone. We have recorded an interesting example of this: a dislocation of the shoulder occurred in a young man aged twenty-two; it proved irreducible, so the joint was laid open and the head of the humerus was found to be grasped by two firm bands which formed part of the capsule. When these were divided the dislocation was easily reduced. The importance of energetic

Digitized by Google

treatment of acute inflammation in the ends of long bones in children is dwelt on in a paper by Mr. W. H. BATTLE. In many cases the only chance of preventing involvement of the neighbouring joint, or even of saving the child's life, is afforded by early incision down to the bone, with, if necessary, trephining. Unfortunately, these cases are often not recognised until it is too late to save the joint. Phelps's open operation for severe cases of talipes is being more frequently performed; an interesting modification of it has been suggested and carried out by Mr. T. H. KELLOCK; in this a flap of the redundant skin on the outer side of the foot is used to fill up in part the large open wound on the inner side; the result was excellent.

In the treatment of fractures the results usually obtained appear good, but Mr. BEDDOE has pointed out that if the cases are followed up the results do not appear nearly so satisfactory, for out of sixteen cases of fracture of the femur only four patients could do their work as well as they could before. To remedy this Mr. BEDDOE suggests, as Mr. ARBUTHNOT LANE has suggested before, that fractures should always be wired. The treatment of enlargement of the prostate by castration is on the whole growing in favour, but it is by no means rare for deaths to follow the operation; this is probably to be explained by the very diseased condition of the kidneys usually present in long-continued prostatic enlargement. In a series of 111 cases, collected by Professor WHITE of Philadelphia, twenty patients died, but in 87 per cent. of all the cases rapid atrophy of the prostate occurred. Mr. MANSELL MOULLIN considers that the early rapid diminution in size which the prostate undergoes after castration is the result of the shrinking of its bloodvessels, and that it is not till later that true atrophy occurs. Mr. C. B. LOCKWOOD has advocated the radical cure of hydrocele by excision of the sac, and the results obtained by this method compare favourably with those of injection, but most surgeons will hesitate to adopt the proposed method in all cases. Cases of extensive malignant disease of the breast are sometimes not operated on because of the difficulty of providing sufficient covering for the large wound which must result. For these cases Mr. ARBUTHNOT LANE suggests removal of the upper limb at the shoulder in order to provide the covering required from the skin of the arm; the subclavian vessels are tied in the third part. The result of a case in which this was done was very satisfactory, but the operation was performed so recently that at present no certain opinion can be expressed as to its practical value.

Obstetrics and Gynæcology.

During the past year considerable activity has prevailed in both the departments indicated by the above heading. It would be impossible within the limits at our disposal to do more than refer briefly to some portions of the work that appear especially deserving of attention. Professor C. B. PENROSE in May last communicated to the American Gynæcological Society an instructive paper on Bacteriology in Pelvic Surgery. The pathogenic organisms present in inflammation of the uterine appendages are the gonococcus, the streptococcus and staphylococcus, the bacillus coli communis, the tubercle bacillus, and the pneumococcus. He divides the great number of cases of pyosalpinx into two groups—those due primarily to the gonococcus and due to venereal infection, and those due to the staphylococcus and streptococcus and connected with septic infection after labour, abortion, or operation. The bacillus coli communis enters the abscess cavity secondarily through the wall of adherent intestine. A micro-organism is to be found at some stage in all cases of suppuration in connexion with the uterine appendages, but all pelvic abscesses do not contain organisms; after a time they die, and the pus is then sterile. Apparently, also, the danger of septic peritonitis depends greatly on the kind of micro-organism in the pus; it would seem that pus in which gonococci alone are present is less dangerous than when some of the other micro-organisms are present also. Generally, septic peritonitis is due to the staphylococcus, streptococcus, and bacillus coli communis. Besides the kind of micro-organism present, much also depends on the kind of fluid in the peritoneum and the condition of the peritoneum itself—whether it be healthy or in some way damaged. Professor PENROSE examines the pus microscopically during the operation in cases where it is impossible to remove the pus sac unruptured; if the pus is sterile he does not wash out or drain, but if organisms are found he washes out and drains. The operation of vaginal hysterectomy for disease of the uterine appendages is not one with which most of us here are very familiar. An essential condition in undertaking vaginal hysterectomy used to be that the uterus should be freely movable, so that it could be easily drawn down to the outlet of the vulva. Fixation of the uterus is no longer regarded as a contra-indication.

There is, no doubt, a good deal to be said in favour of the operation in the cases under consideration as opposed to removal of the uterine appendages. The fact that in the latter operation the uterus is left is not in itself of any great advantage, for without its appendages the uterus is practically useless. The removal of the uterus by the vaginal method certainly has advantages in regard to affording free drainage; and it is claimed that the mortality is very low. The technical details of the operation as given by Dr. GILLIAM of Columbus, Ohio, do not appear to present any great difficulty. After freeing the cervix and securing the vessels at the sides it is split laterally and each half amputated, a fresh hold being taken of the part of the uterus above before the whole cervix is cut away. When the bladder has been dissected off, the anterior wall of the uterus is split longitudinally and removed piecemeal; forceps to secure the vessels are applied according as this appears necessary, and the remainder of the uterus is removed. The appendages are removed if this seems practicable; if otherwise they are left. Collections of pus in the neighbourhood of the uterus are opened up, washed out, and drained. Dr. GILLIAM admits, however, that under favourable conditions many of the ailments connected with the tubes cease, and he thinks only a very few reach a stage at which removal of the appendages, or removal of the whole uterus, becomes necessary; but he says: "When the destructive changes of pelvic inflammation have gone on to such an extent as to be practically beyond the reach of the cœliotomist PÉAN steps in, and by removing the uterus per vaginam makes possible a perfect recovery." Dr. BALDY records six cases of removal of the uterus subsequently to

Digitized by Google

removal of the appendages, the latter operation having failed to relieve the symptoms. The result of the hysterectomy was completely satisfactory in this respect. As Dr. BALDY truly says: "There is no one who has practised gynæcological surgery to even a limited extent but knows that patients suffering from chronic pelvic inflammatory disease are not always cured of their symptoms by the removal of the tubes and the ovaries alone." It remains to be seen whether the same will be true of hysterectomy in such cases. We believe the operation has only been tried to a very small extent as yet in this country. Dr. BALDY has collected a list of 223 cases with only six deaths. In connexion with hysterectomy, it may here be mentioned that several abdominal hysterectomies have now been performed in cases of puerperal septicæmia, where milder measures appeared to be unavailing. The operation in such circumstances cannot yet be said to have passed beyond the purely experimental stage. Dr. MORDECAI PRICE read a paper before the Philadelphia Medical Society on Hysterectomy for Puerperal Infection, in which he expressed the opinion that the operation in such circumstances is nothing less than a criminal procedure. He instances a typical case three days after labour with a high temperature (103° to 106° F. or more), with all symptoms at the very worst. Granting that the cause of the trouble is in the uterus, he objects to the use of the sharp curette for dealing with the interior of the uterus, and insists that with the finger alone every particle of membrane and placenta remaining after labour can be removed, if not without ether, then with it. In his opinion the finger will remove all that should be removed, and that without wounding the parts in the least. He follows this treatment by washing out the uterus through a double-channelled tube—first with an antiseptic, and then with pure water only at a temperature of 110°. Without going so far as to deprecate the use of the curette entirely in such cases, we think that undoubtedly in the large majority what needs to be done can be done with the finger alone better and more safely than with any instrument. Obstetricians of large experience will agree with Dr. M. PRICE that among septic puerperal cases it is at times utterly impossible to say what cases will recover, and that some of those apparently in a desperate state get well. When this has been admitted to be so, the difficulty of selecting for surgical treatment—that is to say, for abdominal hysterectomy—those cases that will die if left alone must be obvious; and, again, a similar difficulty arises in the other direction, for how, if we cannot often say what the result will be in these cases, are we to avoid subjecting women, who left alone will recover, to the danger of a formidable operation, and more especially formidable in the circumstances as to strength in which it is to be undertaken? It is true that Dr. BALDY has reported a series of nineteen abdominal hysterectomies for puerperal sepsis with seven successes, or, in other words, with twelve deaths. Granting the extreme difficulty of the prognosis, it is by no means certain that in the twelve fatal cases all the patients would have died if left alone; the probability, indeed, seems to us rather the other way.

The treatment of puerperal sepsis by injections of anti-streptococcic serum has come into some degree of prominence during the year; two cases so treated by Professor GAULARD of Lille, for instance, are recorded in the December number of the *Revue Obstétricale Internationale*. One case terminated favourably, the other died. In the fatal case he is inclined to attribute the result to the injections, and considers that we need information and experience as to the dose and the indications for repeating it. He does not consider that the use of injections should cause us to be less ready to use the curette, and to make sure that the uterine cavity has been thoroughly cleared out. This should be done before having recourse to the injections. Here, again, the same difficulty arises, many very bad cases recover perfectly without the use of injections of the serum, and it will be very difficult to conclude that recovery is to be attributed to the injections. On the other hand, the use of them carries with it a danger of its own.

Therapeutic Progress.

The impetus imparted to the study of serum therapeutics during 1894 by the sanguine reports of its success in diphtheria has been fully maintained during 1895; for the present this subject appears to have eclipsed the interest of the older remedies, vegetable, mineral, or synthetic, and literature teems with records of trials, successes, and failures, from which it may well be hoped that some permanent benefits may be obtained. Attention has been so far riveted to this subject that a learned professor of therapeutics lately announced that sero-therapy and its therapeutical applications would form the subject of his winter course of lectures, to the exclusion of current medication by means of drugs. Doubtless there will be a return swing of the pendulum, but meanwhile we must note with approval the eagerness with which this logical outcome of bacteriology is being tested and discussed. The debate on the antitoxin treatment of diphtheria at Munich indicated a general belief in the great reduction of mortality, which was by many attributed to an arrest of the disease at an early stage before the larynx was involved. Opinions differed as to the relative frequency of post-diphtheritic paralysis, but even those who thought it was increased held that this was to be explained by the greater number who recovered. The chorus of praise was marred by a few discordant notes from those who were unconvinced and attributed the undoubted alteration in mortality to the mildness of the epidemic; but in the end the majority agreed that the antitoxin treatment had done no harm, that there was evidence that it had done much good, and that, for the present, the production of immunity must be considered not proven. It is interesting to compare this debate with the later discussion on serum therapeutics at the meeting of the British Medical Association, where diphtheritic antitoxin claimed the greater share of attention, but was considered from various standpoints, many references being made to the methods of preparation and preservation. Valuable papers have appeared upon the preparation of antirabic serum and upon the method of determining its strength. An antitoxin has been described for carcinoma, and there is some evidence that under its use the general condition is improved and the size of tumours diminished. Streptococcus antitoxin, or anti-streptococcic serum, has been used for puerperal septicæmia

Digitized by Google

and erysipelas. Tetanus antitoxin was described at the British Medical Association meeting, and careful notes of several cases of traumatic tetanus—many successful—have since appeared in our columns; the prophylactic action for veterinary purposes has also received notice. Tetanus has also been treated with hypodermic injections of carbolic acid, as well as with morphia, opium, and chloral. Antivenene, whose antidotal powers are attributed to chemical rather than physiological action, has been recommended for the production of immunity from snake-bites, for the treatment of which strychnine and local injections of chloride of lime have also been employed, but not with very encouraging results. In view of the high rate of mortality hitherto the rule with most of the diseases for which the aid of sero-therapy has been invoked, the importance of the subject cannot be overrated, even though the present wave of enthusiasm almost challenges scepticism.

The interest inseparable from the active preparation of a new edition of the British Pharmacopœia has diverted a large share of energy from matters of clinical importance. Numerous suggestions for improvement have been made, and the requirements of the medical profession were considered at the meeting of the British Medical Association.

Cardiac therapeutics were discussed at some length at the Medico-Chirurgical Society of Edinburgh, and included consideration of the SCHOTT or Nauheim treatment, of OERTEL'S treatment, and of the relative value of diet, of arsenic, nitrites, morphine, strychnine, strophanthus, digitalis, and other remedies calculated to remove fluids or to increase elimination. A paper in these columns on the mechanico-gymnastic and balneo-therapeutic treatment of chronic cardiac disorders indicates that the Nauheim treatment was fully described in 1878, and that its employment is not advisable in cases which fail to react with medicaments such as digitalis. Rules guiding the selection of cardiac tonics have been formulated, strophanthus being preferred to digitalis. Acute rheumatic endocarditis has been stated to be most successfully treated by counter-irritation in conjunction with iodide of potassium or iodide of sodium. The value of mercury, and the *rôle* of alcohol in the treatment of heart disease, have also been considered, while attention has once more been directed to the influence of opium on disturbance of cardiac rhythm due to irritation of the alimentary tract. A research concerning some new vaso-dilators has indicated that erythrol tetranitrate and mannitol hexanitrate can produce a prolonged fall of blood-pressure due to dilatation of arterioles. Antipyrin has been recommended as a hæmostatic in aneurysm, while in leukæmia arsenic, administered hypodermically, is stated to be the most satisfactory of all remedies hitherto proposed.

At the Congress of Medicine at Munich an extremely important discussion was held upon the therapeutic action of ferruginous compounds; BUNGE urged the dietetic use of ferruginous vegetable products, and stated that ferruginous drugs act only by suggestion; while QUINCKE was convinced of the use of ferruginous preparations, especially of the suboxides and albuminates. He maintained that organic compounds were not preferable to inorganic, the inorganic iron being changed in the intestine to an organic combination; he concluded by saying that drugs cannot be dispensed with in the treatment of chlorosis, a conclusion with which most practitioners will cordially agree. The course of the recent discussion on the treatment of acute lobar or croupous pneumonia elicited very few new facts; oxygen inhalations and the use of perchloride of iron, of morphine and strophine, strychnine, caffeine, and digitalis were referred to, but the consensus of opinion appeared to indicate that the claims of antitoxic treatment were premature, that ice applications had not gained in favour except for the relief of pain, and that there might be some risks in the reduction of fever by drugs that are not distinctly inimical to micro-organisms. On the other hand, it is worth noting that the cold bath has been employed in the pneumonia of children in France, and that it is stated to be more efficacious than when used for adults. The pharmacology of the ipecacuanha alkaloids has been lately studied, and it is held that cephæline is the more powerful emetic, while emetine, although emetic in large doses, is the more powerful expectorant. On these grounds it has been urged that the alkaloids might give more constant and more satisfactory results than preparations derived from the plant, in which their relative proportions are subject to variations. Amongst recent suggestions for the treatment of phthisis may be mentioned chloride of ammonium, para-chlorophenol, and fluoride of calcium, the last named being especially indicated in tuberculosis in infants. Acute catarrh has been treated with sulphanilic acid, douches of carbonic acid are said to have cured anosmia and also ordinary common colds, and cocaine has been employed, apparently with good results, in whooping-cough.

Several monographs indicate that papain is gaining favour in the treatment of various forms of dyspepsia, from simple atonic dyspepsia to that associated with gastric ulcer, when it is said to promote cicatrisation. It is stated, however, that it is most efficacious when given with other drugs. Bichromate of potassium has also been recommended for chronic dyspepsia and other affections of the stomach. In the diarrhœa of tubercle and in typhoid fever compounds of bismuth and naphthol have been employed as intestinal antiseptics, while the "radical cure" of chronic dysentery, by daily washing the large intestine with dilute solution of nitrate of silver, has been described. From experiments with aniline colours the rapid absorbent power of the rectum has been confirmed, and it is suggested that large doses of quinine and other drugs might be thus administered. A new drug, uranium nitrate, has been advocated for the treatment of diabetes mellitus, and its power of controlling the secretion of sugar is said to be greater than that possessed by any other drug. For the same disease yeast has been suggested, while uricedin (citrate of potassium, sulphate of sodium, chloride of sodium, and citrate of lithium) has proved of service in the uric acid diathesis. Bromide of lithium has been used in acute and chronic Bright's disease, while, in the acute form more particularly, the external application of pilocarpine or of guaiacol has been commended. Uræmic coma, attended with great cyanosis and loud stertor, has been successfully treated with inhalations

Digitized by Google

of oxygen. Attention has been directed to the dangers of morphia in gynæcological practice, and to the use of salipyrin in menorrhagia and metrorrhagia, and of veratrum viride in eclampsia. Very little has been reported of new antipyretics, but early in the year an interesting paper upon the administration of salicylates in acute rheumatism was published in our columns; for the same disease salophen has been recommended, as well as for chorea and neuralgia. The value of eucalyptus oil as a disinfectant in scarlet fever has been investigated, with somewhat disappointing results. Much has been said in favour of the treatment of diphtheria by sulphur, and by insufflations of sulphur together with tabloids of pure sulphite of magnesium, but these researches are not so numerous or so convincing as those with antitoxin. The recurrence of influenza has led to renewed attention to the prophylactic value of quinine, and, in some quarters, there is general agreement that the hydrochlorate and the hydrobromate possess greater efficacy than the sulphate. As revivals rather than novelties may be mentioned the recommendations of nitrate of silver and of biborate of soda in epilepsy, and perhaps the use of chlorobrom for seasickness should fall in the same category. Trional has been employed as a hypnotic in cases where chloral and sulphonal fail, and it has been of especial service in cases of sleeplessness in children. Chloralose and somnal, two other hypnotics, have also received a certain amount of support, but the latter is contraindicated by any gastro-intestinal disturbance. Comparatively little has been heard of the animal extracts during the year, but thyroid extract has given good results in the treatment of obesity in patients free from indications of myxœdema; it has also been used in goitre, and with marked success in psoriasis. Salicin and salicylates have been highly recommended for psoriasis and other skin affections; they are said to be of great value in the stage of active development, and in hyperæmic cases which are unsuitable for arsenic or thyroid extract; it is further claimed that they are less likely to upset general health than either of the last two. The antisudorific properties of picrotoxine have been made the subject of clinical study, and a peculiar bullous eruption on the hands has been figured and ascribed to the application of iodine liniment to the chest. Serious coma has been accidentally produced by carbolic acid in three recorded cases, in two it resulted from the application of carbolic compresses to the skin, and in the third, an infant, it ensued after the head had been accidentally washed with pure carbolic acid. Serious symptoms have followed the use of cocaine, and in a fatal case of acute poisoning the quantity taken was two drachms of a 10 per cent. solution of the hydrochlorate. A case of poisoning by hypodermic injection of strychnine has been successfully treated, after the development of opisthotonos, by the continuous administration of chloroform for over six hours, and a similar happy result has followed the use of oxygen in morphine poisoning, in which artificial respiration had been necessary. A remarkable case of quinine poisoning, by five or six drachms of the sulphate, was reported at the Indian Medical Congress, the prominent symptoms being paralysis, inertia, and blindness; the patient gradually recovered, but vision remained bad for some months. A dose of five grains of exalgine, in a case of asthma and insomnia, produced symptoms sufficiently serious for it to be classed as a respiratory poison. The relative safety of sulphonal in large doses has been once more demonstrated by a female dipsomaniac who recovered from a dose sufficient to produce sleep for sixty hours. An accident with phenyl-hydroxylamine led to most severe symptoms with marked separation of hæmoglobin; phenacetin rashes have been noted, and the toxic list may be closed by reference to the delirium and unconsciousness caused by *scopolia lurida*, described at the Indian Medical Congress. It will be noted that, with the exception of the last-mentioned, these toxic symptoms have resulted from the accidental or injudicious use of relatively common drugs, and they are included in this account of therapeutic progress of the year either for the success of the treatment employed or for the warnings they convey.

The meeting of the British Medical Association enabled the therapeutic claims of many English hydropathic centres to be dealt with by those having local experience of their value, and the therapeutics of saline laxative mineral waters have also received attention.

In conclusion, it may be noted that earnest protests have been raised against the dogmatism of laboratory teaching and its supposed claim to be the proper foundation of rational therapeutics. We have been reminded of the respect due to the empiricism of antiquity, which has furnished so many of the drugs still employed and trusted by the majority of the profession. Amidst much that is new, the claims of empiricism cannot be ignored; explanatory theories, however satisfactory, do not deprive an empirical discovery of its value, nor do they, strictly speaking, place the discovery within the realm of rational therapeutics. These protests, though timely, indicate a spirit of conservatism; but it must be admitted that, when the work of the laboratory is supported by undoubted clinical experience, like that adduced in favour of some forms of serum therapy, no protests can be effective in checking the march of progress.

Dental Surgery.

During the past year dental surgery may be said to have made sound and steady progress. The British Dental Association, under whose guidance the dental profession has made so much headway in recent times, has again a good year's work to chronicle. The strength of this body has always been in the unity with which it has worked, and as long as this continues its influence will be felt. Such steps, therefore, as that quite recently taken by the Midland Branch of the Association, in sending a vote of thanks to the General Medical Council when the same had not been considered necessary by the representative board, is not a healthy sign. As an outcome, no doubt, of the annual meeting of the Association at Newcastle last year, a dental hospital has been started in that city, and another gratifying point to chronicle is the large number of new dental appointments which have been made to public institutions, in a great measure due to the work of the committee on the teeth of children. During the past year a large number of prosecutions of much interest to dentists have taken place, and included in these have been two cases of evasion of the Act of 1878. The most valuable contributions

Digitized by Google

to dental science have been the articles dealing with the constitution of teeth by Dr. BLACK and Mr. C. S. TOMES. The articles by the former appeared in the *Dental Cosmos*, and the investigations which he carried out must have entailed a large amount of time and labour. The result has been a valuable addition to the knowledge of the teeth and also of the various materials used for filling. Mr. TOMES'S articles appeared in the journal of the British Dental Association, and were in some respects surveys of Dr. BLACK'S, criticised by the light of investigations he had himself undertaken. The results obtained by Mr. TOMES seem to point to the fact that something outside the amount of lime salts is the cause of caries of the teeth, and he throws out a hint that the trouble may be in the amount of water contained in dentine, or, perhaps, not in the dentine at all, but in the enamel. An interesting discussion has taken place on the nature of the translucent zone in carious dentine. In this connexion Mr. F. J. BENNETT has described in dead teeth an appearance similar to the translucent zone, and Dr. MILLER of Berlin towards the close of the year has contributed an article in which, although he inclines to the view that the appearance is only seen in living teeth, still admits that the question is far from being settled. Fresh light has been thrown on the origin of Nasmyth's membrane by Mr. PAUL, and a large amount has been written on coagulents and non-coagulents in the treatment of pulpless teeth. Hardly any books of importance have been published, and the one most worthy of mention is one on "Dental Microscopy" by Mr. A. HOPEWELL SMITH. This book has satisfied a long-felt want. A very valuable paper by Dr. HEWITT has appeared in which he sums up the result of inquiries into the number and causes of deaths which have occurred from the administration of chloroform for dental operations, and his statistics show that the large majority have taken place in Scotland, where chloroform is so frequently administered. Dr. HEWITT'S contribution is a very valuable one, and should go far to settle a much vexed but very important question. By death the dental profession have lost their veteran leader, Sir JOHN TOMES. Although for the last few years he had not been in active practice, his opinion on all matters was always sought, and up to the last he was the guiding spirit of a profession which he truly may be said to have made. The death of Mr. JAMES PARKINSON has also severed one of the few remaining links of the present with the past.

Ophthalmology.

In this department we have to record that the Bowman Lecture was delivered before the Ophthalmological Society of the United Kingdom by Dr. W. R. GOWERS, who took for his theme Subjective Visual Sensations, dealing, in the course of his remarks, with those that occur in connexion with hysteria and epilepsy, the details of the cases being drawn from his own experience. The fourth Boyle Lecture was delivered by Dr. CRUM BROWN on Movements of the Head and Eyes. The meetings of the Ophthalmological Section of the British Medical Association were well attended, and several important papers were read. Three instances of the rare parasitic affection, constituted by the presence of the nematoid worm, named Filaria Oculi, have been placed on record. Two of these were in the same patient, and were under the care of Dr. ARGYLL ROBERTSON. They were both extracted in the living state, and proved to be a male and female specimen of the worm. The third specimen was observed by MM. LACOMTE and COPPEZ, and moved briskly in the anterior chamber without producing iritis. The parasite was critically examined by M. VAN DUYSE. Both patients had resided on the West Coast of Africa. Troubles of the conjunctiva and their treatment occupy, as usual, a considerable space in ophthalmic literature. Dr. MALGAT claims to have been highly successful in the treatment of granular lids by means of electrolysis, a needle forming one pole of a small Gaiffe's battery being applied for a few seconds to each granulation, whilst the other pole is placed on the arm or between the hands. The strength of the current should be about six or seven milliampères. Cocaine renders the little operation painless, and the cicatrices left are slight and produce no inconvenience. It is interesting to find that antitoxin treatment has proved successful in cases of diphtheritic conjunctivitis. From a perusal of the reports of the various cases in which this remedy has been employed with great advantage by Mr. WALTER JESSOP, Dr. MORAX, Dr. TERSON, Dr. H. COPPEZ, M. GAYET, and others, the conclusion may be drawn that, if the treatment is commenced sufficiently early, the symptoms threatening invasion of the cornea by the specific bacilli of diphtheria and consequent serious impairment of vision soon disappear, and complete recovery takes place, adding another to the now numerous evidences of the value of this means of treatment. The pain and inflammation of the conjunctiva that not infrequently follow the employment of the yellow oxide of mercury ointment in cases of phlyctenular ophthalmia when applied in doses sufficiently strong to be really serviceable have led to the trial of other and blander remedies. Amongst others the phenate of mercury and the phenate of gold have been tried by M. GALEZOWSKI. The former when subcutaneously injected has also been found useful, not only in inflammatory troubles of the lids, but in cases of syphilitic affections of the choroid and retina. The phenate of gold it is said may be employed hypodermically with advantage in cases of atrophy and in ataxic conditions of the optic nerve. A substance named sodium sozo-iodolate has been proposed by M. GOLDZIEHER as a remedy in cases of ulcer of the cornea in the proportion of 3 per cent. of vaseline and a small quantity of atropine sulphate. Formol in the proportion of one per thousand of distilled water has been used with success in the same class of cases by M. OLIVIER and by M. FROMAGET when other remedies had failed, and Dr. ROLLAND has vaunted the merits of antipyonin, which he believes possesses the advantages of being soluble, antiseptic, and innocuous, whilst it is very effective in cases of abscesses and ulcers of the cornea, in pannus, and in the various forms of conjunctival inflammation. Signor LAVAGNA recommends the use of formaldehyd as an antiseptic remedy, and one that is especially useful in cases of inflamed lacrymal sac in solutions containing one part in two thousand. Two cases of very serious hæmorrhage from the conjunctiva have been recorded, not apparently associated with hæmophilia. In one of these, a child seven months old, under the care of Dr. STOEVEN, death took place from the

Digitized by Google

hæmorrhage proceeding from a small growth of granular tissue on the inner surface of the lid, whilst the other was seen by Mr. JESSOP, and the source of the hæmorrhage was a depressed jagged ulcer on the palpebral conjunctiva.

The mode of dealing with the cortical substance of the lens left after the extraction of a cataract is one of the most difficult points to determine in ophthalmic surgery. To remove it by operation or to leave it alone is a proceeding equally beset with difficulties, and in many cases the surgeon wishes he had adopted the opposite plan to that he has pursued. M. SERRILLO advises with confidence the introduction of a Beers' knife on the fourth or fifth day after the operation, when the lens substance is softened by absorption of the aqueous. It will be interesting to know his plan of procedure ten years hence, as experience of many cases is requisite before a sound conclusion can be drawn.

The treatment of detached retina has been under discussion on several occasions during the past year, and various methods have been suggested. Dr. C. S. BULL of New York, in addition to rest in the recumbent posture, atropine, and a bandage, has employed pilocarpin hydrochlorate, which, however, as most practitioners have found who have used it, produced such alarming prostration that he ceased to prescribe it; iodide of potassium, puncture of the sclera, division of fixed membranous opacities, and division of the detached retina have all been tried, but in few instances were any of these remedial means satisfactory in their results. An original method of treating this affection has been suggested by Dr. R. DEUTSCHMANN, which has proved of service in some cases, and at least deserves a trial. It consists in injecting into the eye some of the fresh vitreous from the eye of the rabbit by means of which the retraction of the films and filaments in the vitreous, which have been thought to cause the detachment, is prevented. The injection of the vitreous under, of course, aseptic conditions does not appear to be followed by any marked irritation. Mr. NETTLESHIP read a paper at the Ophthalmological Section of the British Medical Association meeting, in which he advocated iridectomy in chronic glaucoma as a general rule, for although in many instances no improvement results, in others the progress of the malady is arrested, whilst in others, again, the restoration of vision is considerable.

The almost uniform occurrence of injury to the exciting eye in cases of sympathetic ophthalmia as well as the results of microscopical investigation have led to the generally accepted view that this disease is due to the introduction of germs into the injured eye, which by one of several routes make their way to the opposite eye, and by exciting inflammation in it destroy or materially deteriorate its power of vision. Various observers have ventured to doubt the truth of this general statement, and other modes in which the troubles characteristic of sympathetic ophthalmia may be produced have been suggested. A very carefully examined case by a competent observer, Mr. W. COLLINS, has been reported in which the microscopical examination of the eyes supplied no evidence whatever of the presence of micro-organisms, and in such case one or other of the explanations given by those who do not admit septic contamination must be admitted.

In an article on the Albuminuric Retinitis of Pregnancy Dr. SILEX of Berlin finds that it occurs in the proportion of 1 case to every 3000 pregnancies, and is fully of opinion, with most authorities in this country, that premature labour should be induced. VAN FLEET, in a paper published in an American journal, is opposed to this proceeding, and doubts whether the physician is justified in sacrificing the life of the fœtus to preserve the vision of the mother. The action of the practitioner would probably be guided by the circumstances of the case. A short but interesting communication to his own *Recueil d'Ophtalmologie* has been made by M. GALEZOWSKI, giving an account of the diseases of the eye he met with in travelling through Persia. He shows incidentally that there are openings in the great countries of the East for some of the younger ophthalmologists, for in requital of the attention to, and interest in, the many cases of diseases of the eye amongst His Majesty's subjects who had come under M. GALEZOWSKI's care the SHAH decided to establish a chair of Ophthalmology and endow it with an annual revenue of about £400, and Dr. RATULD now occupies it with distinction.

The injection of an antiseptic fluid into the anterior chamber of the eye after the operation for the extraction of cataract has again been proposed by M. CHIBRET, who recommends a freshly made solution of mercury cyanide of the strength of 1 in 20,000 of water, and he has devised a special and rather complicated syringe, but the members of the Ophthalmological Society of Paris do not appear to have been greatly taken with the proposal, which is indeed opposed to the disposition of most surgeons to simplify the operation as far as possible. An isolated but very interesting case has been put on record by M. ABADIE in which electrolysis proved of great service. The patient had given way to his temper, and shortly after his vision became dim and in the course of three hours was lost, probably from intra-ocular hæmorrhage. After undergoing some medical treatment without success, he placed himself under the care of M. ABADIE, who inserted an iridised platinum needle into the eye, the opposite (negative) pole being placed on the arm. On the following day the patient was able to count fingers, and in the course of a month could guide himself and read the names of streets.

Observation of the distressing effects of high degrees of myopia has of late years led to the suggestion by FUKALA, SCHWEIGGER and others that the lens should be removed though still perfectly transparent and the excessive refraction diminished. In the event of the operation being successful there can be little doubt that the vision of the patient undergoes considerable improvement, the myopia being reduced about fifteen dioptres, but the risk and uncertainty of the operation, which are thought by many to be greater than in ordinary senile cataract, deter most people from submitting to it. VON HIPPEL, however, brought the subject before the Ophthalmological Congress which met this year at Heidelberg, and stated that he had operated on sixty cases with good results, and his statements were supported by Professor SATTLER, who has also had considerable experience. It should not be resorted to when the myopia is below what is corrected by a 10 D concave glass. VON HIPPEL'S results were good, the patient preferring in all instances the eye that had been operated on to the other; but in Professor SATTLER'S cases the effects were less satisfactory, in some instances being disastrous

Digitized by Google

and in others being unattended with improvement in vision. A totally different method of assisting myopic patients has been reintroduced by Dr. MASSELON and Dr. DE WECKER. It consists in the employment of convex instead of, as usually practised, concave glasses. The principal objection to this plan is that the position of objects as seen by the patients through such glasses is reversed, though it is said that the necessary mental correction is soon learned. The cause of myopia has been referred by Dr. O. BITZOS, after an elaborate inquiry into the subject, to abnormal elasticity of the sclerotic with increase of intra-ocular tension, which last is again due to excessive accommodation or prolonged strain of the eye in working at near objects. The injurious effects of protracted attention to near objects is indubitable, but the increased elasticity of so dense a tissue as the sclerotic seems to be doubtful. The physio-physical conditions by which accommodation is effected, it may be remarked in passing, have been fully considered by Dr. WILHELM SCHOEN.

Apropos of a method of treatment practised by M. WECKER in cases of wounds of the cornea, which consists in freeing the conjunctiva from the sclerotic and bringing it forward by a continuous circular suture and thus rendering the wound subconjunctival, priority in the proposal for performing the operation has been claimed by M. TROUSSEAU. Whoever may have devised it, the proceeding is in some instances very useful if performed under carefully conducted aseptic precautions. In regard to strabismus and the operation for its cure there seems to be a growing disinclination, especially in America, to divide the stronger muscle, but instead to effect by operation the advancement of the weaker muscle, and thus to improve its leverage in bringing about the rotation of the eye. EWALD HERING contests the supposed colour-blindness for blue at the fovea centralis, which was admitted by A. KÖNIG, who thought that the blue-blind area corresponded to a visual area of from 55 to 70 minutes in diameter. He has dealt also with Purkinje's phenomenon—that in the different colours the sensation of brightness is a different function from the absolute degree of light, blue, for example, being brighter than red or green when the light is lowered. W. A. NAGEL has experimented on the sensibility of the bulbar conjunctiva, and has found that of the three sensations of pressure or contact, pain and temperature this membrane possesses chiefly two—pain and cold. The subject of colour vision has been considered in an important treatise by Captain DE W. ABNEY, in which the theories of colour and the chief facts that have been ascertained in regard to the perception of colour are discussed in masterly fashion. Dr. EDRIDGE-GREEN and Mr. BICKERTON have published papers on colour-blindness in which it is pointed out that too great reliance must not be placed on the Holmgren wool test, that examinations for the public services and for railway and other signal-men should be conducted by medical men specially trained in colour-blindness, and that the arrangements for the examination of such an extremely important defect are not even now conducted in a satisfactory manner.

Forensic Medicine.

With the exception of a remarkable case at Sydney, N.S.W., the closing year has not been fertile in furnishing instances of poisoning beyond the usual record. In this case a man was indicted for the murder of his wife by administering *arsenic*. From the facts that both arsenic and strychnia in large quantity were detected in a drink intended for the deceased, and that arsenic was found in the excreta, there can be no doubt that the deceased came to an untimely end. The accused was tried, convicted, and condemned to death. The sentence was afterwards commuted to imprisonment for life, and later the Government on being memorialised ordered a commission, consisting of a lawyer and two medical men, to examine and report. The lawyer was of opinion that the decision of the jury should be endorsed, whilst his *confrères* were not satisfied that it had been proved that the condemned man had caused the poison to be taken by his wife. We need not here detail the subsequent history of the case. But the events above recorded are somewhat analogous to what happened in the Penge case. It will be remembered that four persons were condemned to death for the murder of a woman named STAUNTON by starvation. The expert medical evidence given at the trial left grave doubts whether she had not succumbed to tuberculous meningitis. A weighty representation made by the medical profession in favour of this hypothesis led to the death sentence being commuted in the case of three of the convicts—the fourth was granted a free pardon, as a committee of judges held that the indictment was bad in law. Abroad two cases of poisoning—not fatal—by *creolin* have occurred. In one a woman took with suicidal intent 75 grammes of the substance. She recovered in five days. The symptoms were those of narcosis and severe gastro-intestinal irritation. The poison was excreted mainly by the kidneys. In the other the creolin was used as a 2 per cent. vaginal irrigation. Dr. HERZEN relates a case in the *Révue Medicale de la Suisse Romande* of severe toxic effects from the ingestion of twenty centigrammes of *chloralose*. Convulsions of the muscles of the extremities and those of mastication ensued. These were subdued by hypodermic injections of ether. The patient recovered. A lamentable accident occurred through a druggist's apprentice dispensing one ounce of tincture of opium for black draught. The bottles containing the drugs were carelessly allowed to be in juxtaposition in the shop. Death ensued in three hours. In Yorkshire a woman, on her own confession, took the greater part of a mouse powder, which contained two and a half grains of *strychnia*. The symptoms peculiar to the drug gradually subsided under treatment, but she died from syncope after twenty-four hours. The jury found a verdict of "*Felo de se*." We had occasion to comment strongly on the merits of the case, inasmuch as there was scientific doubt—(1) as to whether she had taken strychnine; (2) as to the cause of death; and (3) as regards the verdict, contending on the latter point that the act, if committed, was in itself *primâ-facie* evidence of insanity, and especially in a person the subject of chronic alcoholism.

Chloroform has been responsible for a number of deaths, the majority of which resulted from inhalation prior to intended surgical operations. Two cases have been reported of the fatal effects of chloroform inhaled to allay pain and procure sleep. In one instance it was shown that a man had delivered at his house two ounces of chloroform daily for eighteen months. In the other a member of our profession fell forwards whilst self-anæsthetised, and so

Digitized by Google

inhaled a lethal dose of the poison. A sad mishap befel the wife of a medical practitioner, who inadvertently swallowed a quantity of chloroform and died within half an hour. The A.C.E. mixture—recommended many years ago by a committee of the Royal Medical and Chirurgical Society—has caused death during its inhalation in one case. Cardiac failure preceded the cessation of respiration. Concerning the analysis of *blood stains*, recent investigation has shown that with improved instruments approximate information may be obtained as to the source of the blood, whether human or not, but considering—(1) that in two animals at least—the guinea-pig and the opossum—the size of the corpuscles is practically the same as in man, and (2) that the shape and dimensions of the cells are subject to marked variation owing to external influences, the information at our service must be regarded rather of scientific interest than as a reliable aid to medico-legal inquiries. As regards the detection of blood an American professor has succeeded in demonstrating by the aid of SORBY'S apparatus its presence when existing in so minute a quantity as $\frac{1}{3000}$th of a grain.

The Society for the Prevention of Cruelty to Children has good reason to be proud of its increasing usefulness. Their last yearly report showed that in only 4 per cent. of the prosecutions instituted by them had the charges been dismissed. We are entirely of opinion that their officers should have a free hand in their attempts at detection of criminal usage of children, whether by actual cruelty or by neglect, and we regret that recently a metropolitan magistrate should have described their action as over-officious. If these officers are not allowed to enter houses without notice of the object of their visits the ends of justice must be thwarted.

On more than one occasion we have had to urge an alteration of the law in its relation to medico-legal procedure. Instances of such desirability are not far to seek. At present medical officers at public institutions are not entitled to fees for making post-mortem examinations and giving evidence at inquests in cases of deaths which have occurred in such institutions. This is clearly an injustice, which was submitted to at the time of the passing of the Coroners Bill to save the measure from being wrecked. Again, it appears from a case heard at the Farnham Petty Sessions that unless the accused is committed for trial the magistrates have no power to order a fee or even travelling expenses for a medical witness.

The recommendations of the London County Council relative to proposed alterations of the law regulating coroners' inquests have been fully dealt with in these columns. We trust that ere long they will receive the sanction of the Legislature. At the beginning of the year no less than three separate cases of fatal accidents at laundries occurred in the metropolis. In Marylebone eight persons lost their lives by fire. To remedy the evil of want of efficient inspection the late HOME SECRETARY dafted a Bill to include laundries in the Factory Act. To render this thoroughly effective it must cover all buildings where work is taken in for profit. We acquiesce in the suggestion that it should be ordered that the fines on conviction under the Margarine Act should go to the prosecuting body, as in the Food and Drugs Act. At the recent Hertford Assizes Mr. Justice HAWKINS when trying a case of rape took occasion to say that since he had not the power in such cases to order "the cat" he refrained from using it where he had—namely, in cases of robbery with violence. No doubt the learned judge is right in wishing he could sentence persons convicted of the former offence to corporal punishment, but we doubt if this is a valid reason for withholding the lash where the Legislature intended it should be used. At the same assizes an interesting point arose as to the jurisdiction of a coroner in committing for trial at a particular court. At the inquest held at Folkestone on the body of Mrs. FLETCHER, who died from the effects of rupture of the uterus, the jury found a verdict of manslaughter against Dr. WIGHT (who was subsequently tried and convicted at the Old Bailey). The coroner committed the accused to be tried at the Maidstone Assizes. The alleged offence and the death occurred in the county of London, and consequently the prisoner had to be tried at the Central Criminal Court. His lordship ordered the recognisances of the witnesses to be binding only for the trial in London. Mr. T. R. ALLINSON, whose name had been removed from the Medical Register for advertising, has been convicted and fined the full amount for practising as a qualified man. If prosecutions were not instituted in such cases the disrolling of a person for unprofessional conduct would be of little avail. We cordially endorse the action of the General Medical Council.

The course taken by Mr. OLIVER PEMBERTON, the Birmingham borough coroner, in requiring the presence at an inquest of a person under arrest for an alleged criminal act in connexion with the death, the cause of which was under investigation, deserves approbation. It is just that an accused person should have the right of hearing the evidence, and if he chooses of testifying on oath or making a statement even in a court of first instance. He cannot be compelled to speak, but by an order of the Lord Chancellor he can be present at the inquiry if he so desires.

This medico-legal review must end with a brief recital of two cases of singular interest. We refer to the Plaistow matricide and the death of a young woman named ROSE ENGLISH, who was found shot in the chest and neck in the same room with her male companion. At the Central Criminal Court ROBERT ALLEN COOMBES was put on his trial for the murder of his mother in cold blood and by premeditation. The facts were unchallenged, for the boy avowed his crime. After a long argument and severe cross examination of the prison medical officer the accused was found to be not in a fit state to plead on the ground of insanity. According to the strict letter of the law he was criminally responsible, as his alienism was not of an intellectual nature—i.e., he probably knew the quality and nature of the act and the difference between right and wrong—the legal definition of insanity as regards criminal responsibility—but his antecedent and then present condition too clearly showed that his moral depravity was great and his inhibitive will-power practically *nil*. We trust the circumstances of this crime and the subsequent legal procedure will stimulate Parliament to bring the criminal law into accord with common sense and medical belief. At present it is an anomaly, and, what is more, unjust.

In reference to the death of ROSE ENGLISH, the expert

Digitized by Google

medical testimony given at the inquest was to the effect that the fatal wounds might possibly have been self-inflicted, but that this was in the highest degree improbable. The jury returned a verdict of "Suicide." We are of opinion that the Public Prosecutor acted wisely in not taking further action.

Biology and Physiology.

No better evidence of the activity and interest with which physiological science is pursued at the present day both in this country and abroad can be given than the fact that PFLÜGER'S *Archiv*, the parts of which for many years only formed one modest volume per annum, is now represented by three and contains an astonishing number of articles of which it is very difficult to notice even those that are especially important. A less, but still considerable, increase has taken place in MICHAEL FOSTER'S *Journal of Physiology* and in the *Quarterly Journal of Microscopical Science*. Great attention continues to be directed by microscopists and histologists to the characters and structure of the cell both in plants and in animals. Mr. A. SEDGWICK has indeed given a note of warning that too much stress may be laid upon the cell in development as a unit of the organism, and that in reality the several tissues proceed from a multiplication of nuclei and run into one another by almost imperceptible gradations, but the subject has great attractions, and a large number of observations upon cells have been made and recorded by VERWORN, SCHLATER, REINKE, STRASSBURGER, WAGER, KANTHACK, HARDY, and others, but especially by HEIDENHAIN, who in an elaborate article contained in the *Archiv für Mikroskopische Anatomie* describes the central corpuscles and nuclei of cells, and introduces or uses many new terms which almost require an education to understand, such, for example, as centrosome, astrosphere, archoplasm, mesocentrum, and megacaryocyte. Professor ERNEST HAECKEL has published two parts of his valuable work on systematic phylogeny, one of which is occupied with the Protesta and Plants and the other with the Vertebrata. The phylogeny of the invertebrata remains to complete the work. An endeavour is here made to follow the gradual development of both plants and animals from the very earliest and simplest to the latest and most complex forms. Perhaps no other biologist is so competent to fulfil this task as the author who has set himself to accomplish it. It will be interesting to know whether the facts at his command afford satisfactory evidence of the development of the vertebrate series from the great stem of the mollusca through the tunicata or from the arthropod division of the animal kingdom, plausible reasons for each of which have been lately advanced.

Some interesting work in physiological chemistry has been done by Dr. W. HALLIBURTON on certain tissue extracts which contain nuclein and have been named nucleoproteids, and by the same experimenter in conjunction with Dr. S. W. PICKERING and with Dr. T. GRIGOR BRODIE on intravascular clotting resulting from intravenous injection of certain artificially made colloid substances. These compounds in their chief reactions closely resemble proteids, some containing, whilst others are destitute of, phosphorus. This line of research may prove to have an important bearing on intravenous clotting from disease, as well as on that produced by the venom of snakes. Dr. E. SALKOWSKI and Dr. HAHN have shown that the splitting of the casein molecule which takes place in digestion is due to the specific action of pepsin, and that whilst one part is dissolved and absorbed the other remains insoluble as paranuclein. Dr. A. GARROD has continued his researches upon the unstable pigments of the urine. The analyses of Dr. RALPH STOCKMAN show that the iron metabolism of the body is small, and that the quantity of iron in the dietary of healthy persons with good appetite only amounts to about eight or ten milligrammes per diem, which is a strong argument against the large doses of iron that were, and still perhaps are, sometimes given. The necessity for obtaining precise details in regard to the anatomy of the nervous system such as will satisfy the requirements of the clinical observer, whose horizon has been so greatly extended by the experimentalist, has led to many careful histological researches and to the publication of numerous treatises and memoirs on this subject. Some of these, like the works of DÉJÉRINE and DEBIERRE, are exclusively devoted to the anatomy and histology of the brain and spinal cord, whilst others, like those of TESTUT and POIRIER, only deal with the centres as a part of general anatomy, but in both cases the comprehension of the structure of these organs as given in the text is greatly facilitated by numerous woodcuts, many of which are original, and in nearly all cases beautifully executed. Nor have workers been wanting to investigate the physiology of the nervous system. Some remarkable experiments have been made by Dr. MOTT and Professor SHERRINGTON, which show that section of all the sensory roots of the nerves distributed to a limb is followed by permanent motor paralysis in addition to the anæsthesia which might naturally be expected to occur, from which they conclude that the whole sensory path, from periphery to cortex cerebri, is in action during voluntary movement. The assumption that such motor centres exist in the cortex cerebri has been combated by Dr. BASTIAN, who maintains that there are no motor, but only sensory centres in this region; sensory impressions and the activity of sensory centres being the real guides for volitional action, and the true motor centres only existing in the spinal cord. In connexion with this it is interesting to observe that Dr. E. STEINACH has quite recently shown that the posterior roots of the spinal nerves are not exclusively sensory, but that they also contain motor fibres which are distributed to the visceral muscles originally developed from the lateral plates in the embryo. Dr. FRASER HARRIS has studied the rapidity with which the impulses producing voluntary tetanus succeed each other, and after trying many different methods of experimentation finds that the contraction of the muscle is not a complete but an incomplete tetanus, and that the rhythm of the volitional impulses proceeding from cerebral motor areas has an average rate of from ten to twelve per second, or that it has some higher rate transmuted into one of ten or twelve per second by the activity of the motor cells of the anterior cornua of the spinal cord. The experiments of GRIGORESCU show that the rapidity of transmission of sensory impressions and of motor impulses is the same in the sciatic nerve and spinal cord. The absolute rapidity of sensory impressions in the sciatic nerve and cord together is from about twenty-five to about thirty-one metres per second. In the cord alone it is upwards of

Digitized by Google

fifty-one metres per second, so that time is lost in the transference of the sensory impression from the terminals of the sciatic nerve in the cord to the cells of the cord. In locomotor ataxy the speed is slower in both, but especially in the cord. OEHL demonstrates that the speed is slower, the difference being as thirty-five is to forty-one. Amongst the minor communications on the nervous system may be mentioned that by Dr. M. GROSSMAN, who has demonstrated that the inhibitory fibres of the heart are formed by the three or four lower fasciculi of the vagus and the uppermost fasciculus of the spinal accessory nerve; that by FRANZ HOFMANN, who has satisfied himself that in the frog's heart the vagal fibres which cause variations in the frequency of the beats do not run in the septal nerves, whilst those that modify the strength of the ventricular contraction and the tone of the ventricle run in the septal nerves; that of Dr. H. BORUTTAU on the functions of the vagal branches distributed to the lungs; that of Mr. LANGLEY on the regeneration after section of the sympathetic nerve; that of Dr. K. PANDI on the cortical mechanism of reflex acts, a mechanism which he believes to be uniformly present in the animal kingdom; and lastly, that of Dr. A. G. LEVY on the elasticity of brain, a point of some importance in regard to the growth of tumours and the penetration of foreign bodies into it.

In regard to the blood and circulatory system the origin of the blood corpuscles is referred by M. WERNICKI to the eosinophile layer of the cancellous tissue of bone, the granules of which receive a coating of hæmoglobin at the spleen and then constitute the hæmatoblasts of HAYEM, and this appears to be the view of Dr. SACHAROFF; but a difficulty arises from the fact pointed out by SIAROCILEO, that the rays, the blood of which contains abundance of eosinophile cells, have no bones, and therefore no cancellous tissue. WERNICKI thinks all the white corpuscles have the same origin, that they are short lived, and after escaping from the vessels by a diapedesis nourish the tissues. The glycolytic ferment contained in the blood has been carefully examined by HAMBURGER, who names it glycase, a ferment hitherto only found in plants. It converts starch into sugar much more slowly, but as effectively as the ferment of the salivary, pancreatic, or intestinal ferments. The activity of the ferment, according to J. ABELOUS and G. BIARMÈS, differs in different animals and at different ages. D. B. DANILWOSKY has shown that the intravenous injection of infusion of spleen causes great increase in the quantity of hæmoglobin and of blood corpuscles. The effects on the white corpuscles of defibrinating blood and of the act of coagulation have been carefully studied by Dr. W. HARMSEN, who finds that many are destroyed in these processes, the proportion of the uninucleated differing from that of the multinucleated. Dr. O. LANGENDORFF has applied the methods of the LUDWIG school for preserving the vitality of the excited heart in frogs by artificially feeding it with defibrinated, filtered, and warmed blood to the mammalian heart, and has restored it to activity even after the lapse of ten minutes after total cessation of contraction. VON ZIEMSSEN has employed a sphygmomanometer devised by VON BASCH, which appears to be constructed on the principle of an aneroid barometer, and from its delicacy may prove of service in clinical research. He finds the normal tension in the temporal artery to be from 80 to 110 mm. of mercury. In a case of arterio-sclerosis with cardiac hypertrophy it rose to 180 to 210 mm. mercury, and in a case of valvular insufficience fell to 50 mm. mercury. Messrs. BAYLISS and HILL have endeavoured to determine the relation between the pressure in the cranial cavity and the blood supply to the brain, and incidentally support the views of KELLIE, enunciated long ago, in regard to the constancy of the absolute quantity of blood in the cranial cavity, though its distribution in arteries, capillaries, and sinuses respectively may vary. The experiments of LAUDER BRUNTON and TUNNICLIFFE afford an explanation of the beneficial effects of massage by showing that it causes increased flow of blood through the muscles during and after the massage, whilst the blood pressure at first rose, then fell, and diminished considerably after the massage had ceased. This they attribute to a primary contraction of the blood-vessels followed by relaxation. Observations throwing some light on the obscure functions of the suprarenal capsules have been made by Dr. OLIVER and Professor SCHÄFER. From their experiments it appears that whilst extracts of the cortical portion of these bodies are comparatively inert, extracts of the medullary portion have an extraordinary power, when injected into the vessels, of increasing arterial blood pressure, raising it from two to five times the normal tension, apparently by causing contraction of the systemic arterioles. The somewhat paradoxical difference in the effects of the medullary, as compared with the cortical extract of the same organ, is perhaps associated with the totally different developmental origin of the two parts, the medullary portion being derived from the epiblast (or rather the sympathetic nerve mass) and the cortical part from the mesoblast—the two parts being, as BALFOUR showed, quite distinct in the cartilaginous fishes.

Anæsthetics.

No very definite pronouncement dealing with the death-rate under anæsthetics has been made during the past year. At the same time much useful work has been done and serviceable information collected. GURLT, continuing the statistics from Germany, gives the mortality under chloroform as 23 deaths in 31,803 cases, and under ether 5 deaths in 15,712 cases. In 1894 the deaths were 17 in 32,725 under chloroform, showing an enhanced death-rate for the present year. GURLT refers to complications due to ether, which, although not showing themselves at the time of the operation, should, he thinks, be reckoned in comparing the two anæsthetics. Ether has been found unfavourable in laparotomy. The unsatisfactory results probably arise from the faulty methods employed in Germany for the exhibition of ether. Chloroform in parturition has been studied by Dr. BEDFORD BROWN. He has collected 40 deaths. The comparative immunity from danger enjoyed by parturients is due, he opines, to changes occurring in the vaso-motor system in pregnancy. He uses chloroform lightly in all stages of labour, and to its full degree to relax muscular spasm and rigidity of the os. There is no reason, he thinks, to regard chloroform as lessening uterine contractions or promoting hæmorrhage. Various observers have advocated measures to be adopted

Digitized by Google

anticipatory of, or corrective to, danger arising from chloroform. The pupils during narcosis have been carefully studied by JOSEPH WHITE, WARD, GILL, and others. In the second stage the eyes wander and the pupils dilate; in the third the eyes are fixed, the pupils contract, and GILL regards a pin-point pupil as a criterion of safety. In the fourth stage the eye is fixed and the pupil widely dilated, the sympathetic being paralysed. The effect of electrical stimulation by faradaic currents is shown by ROCKWELL and VON ZIEMSSEN to be really respiratory and not cardiac. The accelerator fibres are more active than the inhibitory. Laborde's method of stimulation by rhythmic traction upon the tongue has been well spoken of by LABBÉ, VERNEUIL, and WARNOTS. BOBROFF, experimenting on lower animals, has used artificially prepared serum for subcutaneous injection in cardiac syncope. He uses five drachms to six drachms and a half. PONCET records some cases in which he performed tracheotomy for respiratory difficulty under anæsthetics. The patients were apparently dead from non-entrance of air into the lungs, and the operation was performed with the view of effecting a rapid ventilation of the pulmonary area. The results induced PONCET to believe that many lives would be saved if early tracheotomy were done, even when no physical impediment existed preventing the entrance of air. BAIXER has drawn attention to the increased perils diabetes causes when chloroform is used. Discussing the causation of death under chloroform, LAUDER BRUNTON has in our columns produced weighty reasons in favour of the view that in poisoning by chloroform the nerve centres are primarily affected, a neuroparesis being brought about.

HAIG has observed that when uric acid exists in undue quantity in the organism there is an abnormal blood pressure. Under chloroform the pressure of the blood is in the initial stage lowered, but as the patient passes out of chloroform this depression gives place to a great increment in blood pressure. This HAIG believes is a source of marked danger to a diseased heart, and if it be present coincidently with the uric acid tension may lead to syncope and death. The association of uric acid toxæmia with death from chloroform has, however, yet to be substantiated. The dangers remotely due to ether have been noticed above; they have during the year been carefully studied by NAUWERCK. BRUN'S view was that ether becomes contaminated by oxidation products and other impurities, and his opinion was corroborated to a certain extent by the experiments of LOWIT, but NAUWERCK advances cogent arguments to show that so-called ether pneumonia is, at all events in his experience, not the result of ether at all, but the effect of auto-infection of the patient's lungs by the septic contents of his mouth and nasal passages. POPPERT records 8 cases in which he believes that pulmonary œdema has resulted from ether. MIKULICZ has also had unfortunate experience with this anæsthetic, and sums it up as (α) 3 cases in which asphyxia occurred during etherisation; (β) 2 deaths from collapse; and (γ) pulmonary difficulties—viz., œdema of the lungs 2 cases, and acute bronchitis 4 cases. MIKULICZ, however, has overlooked two sources of grave fallacy—viz., the excessive quantities of ether given to his patients and the imperfect precautions taken to avoid loss of bodily heat during the operation, due largely to irrigation, wet towels, and other accessories of the antiseptic method. That lowering of bodily temperature takes place under ether has been demonstrated by ANGELESCO, who places it at about 3°F. The loss is proportional to the length of the inhalation, or more probably to the quantity of ether taken in, and is the index of the evaporation heat taken from the lungs. PORTER'S paper opportunely points out that the genesis of much of the so-called ether bronchitis is to be sought in the fact that patients are taken after a prolonged operation under ether in a hot and ill-ventilated theatre into cold and draughty wards. In this connexion the study of the blood during ether narcosis possesses particular importance, and Dr. DA COSTA'S research has advanced our knowledge to a material extent. Although the number of cases studied were too few for us to accept his conclusions as absolutely proven, yet they are of the greatest interest. He found that the hæmoglobin was lessened, thus accounting for the lessened oxidation, and that this was more especially the case when the patients were anæmic at the time of the operation, whether the anæmia was primary or secondary to hæmorrhage. He believes that the blood stream is chilled by prolonged anæsthesia, and suggests that this may cause nephritis and pulmonary complications. He did not find that age exercised any effect. The important results arrived at by MICHELI of Bologna, WUNDERLICH, ALBER, and RINDSKOPFF must not be omitted. They deny *in toto* that the "late effects" such as bronchitis, nephritis, and pneumonia are to be attributed to ether. They investigated a large number of cases, and found that albuminuria never or very rarely occurred *de novo* after ether, and was when present quite transitory. LEPINE asserted before the Lyons Congress that, provided ether was pure, it did not give rise to bronchial irritation even when antecedent bronchial catarrh existed CHALOT goes further. Quoting LINDH, NICOLAYSEN, LASSEN, ASK, and others, he asserts that the "late effects" of chloroform are more numerous than those of ether.

Mr. NEVE published in our columns an important paper on anæsthetics, read before the Indian Medical Congress. From an experience of 6000 cases in the Kashmir Hospital without a death he had seen dangerous symptoms — e.g., primary syncope from fear in early narcosis, laryngeal spasm, &c. During the year further experiments have been made with Schleich's injections of weak cocaine solutions, and many observers have spoken highly of this method of achieving a local anæsthesia. FERRAUD and LUCAS CHAMPIONNIÈRE have used gaïcol as a local anæsthetic. Several fresh inhalers have been introduced, notably improvements in Krohne's chloroform inhaler and the Birch-Rumboll nitrous oxide gas and ether inhaler; while Dr. CARTER has introduced an apparatus on the principle of Junker's inhaler, but intended for ether, which he regards as an advance in so far as its obviates any cyanosis during the use of ether. The special Clinical Report which we have published in the columns of THE LANCET and the reports of the Hyderabad Chloroform Commissions have been collected together for issue in one volume, and will, we venture to think, constitute the most important collection of clinical facts dealing with anæsthetics since the publication of the report of the Royal Medical and Chirurgical Society in 1864.

Mirror of Hospital Practice.

A review of the cases which we have published in the Mirror of Hospital Practice during the past year shows how very important are the clinical facts brought before the profession in this department of THE LANCET. Our contributors are world-wide and their contributions so varied in character that it is difficult at this time of the year, when we give our annual review, to know which to choose for special mention. It is from the surgical wards this year that the largest number of our records are drawn, and, therefore, in our Annus Medicus it follows that we must direct attention more particularly to the successes of surgery. It will, however, be seen that in a large number the assistance of the physician was given, and without his early appreciation of the gravity of the disease success could not have been attained. As time goes on the usefulness of the diphtheria antitoxin is becoming better known and its scope more defined, but early in the year it was not understood to the same extent as it is now, and the series of cases which we published helped to direct the careful attention of the profession to this remedy. The curative effect of tetanus antitoxin has been less certainly established, and we have brought forward cases in which it has proved unsuccessful. We cannot, however, say that it is of no use—further observations are required; but as the disease is rare in this country opportunities of investigation are not numerous, whilst the remedy is sometimes difficult to procure.

The value of syphonage and other methods of treatment of simple dilatation of the stomach, as met with in some of the large vegetable eaters of some of our rural districts, was shown in a series of cases.

A very limited field for the successful employment of the surgeon's art is that afforded by meningitis and hydrocephalus. Quite recently surgeons were content to perform paracentesis of the lateral ventricle and draw off a small amount of fluid, perhaps repeating the operation later if a child developed coma as a result of excess of fluid in the ventricles of the brain. As these cases always terminated fatally it was suggested that the subarachnoid space should be drained through a trephine opening in the occipital bone; of this method of treatment we have published the following examples during the past year: 1. A youth aged eighteen years suffered for eighteen months from attacks of giddiness with severe headache. Other symptoms followed, and at the time of the operation there were all the symptoms of intracranial pressure. After the trephining of the right cerebellar fossa the finger passed towards the fourth ventricle and encountered a soft, bulging membrane (the posterior medullary velum), which gave way and allowed the exit of much cerebro-spinal fluid. The symptoms were at once relieved, and the patient made an uninterrupted recovery. 2. This was the case of a male child aged three and a half years, the subject of chronic hydrocephalus. An opening was made to one side of the middle line with a gouge, the dura mater was incised, and a probe passed to the fourth ventricle. Drainage was kept up for twenty-eight days, and the patient recovered in a very satisfactory manner. 3. This was a male child aged five months, who suffered from chronic hydrocephalus and fits. Basal drainage was effected, but a too rapid flow of fluid occurred, and the child died from hyperpyrexia. We have mentioned during the year five other cases of operation for meningitis. Of these the following was the only successful one of the number. The patient was a girl aged thirteen, who had been ailing for a few weeks, and had been ill in bed for seven days. There were symptoms of meningitis with advancing coma. Trephining on the right side above the level of the lateral sinus was effected, the dura mater was incised, and a large quantity of clear fluid drained away. The lateral sinus was wounded and the opening was plugged. There was much oozing of clear fluid from the wound. She had attacks of headache and fever which were relieved by passing dressing forceps to open up the wound again. Perfect recovery ensued. All these cases illustrate the necessity for early operation if anything like success is to be expected; there is little prospect of success if the patient has been comatose for some days.

We have published several cases of thrombosis of the lateral sinus secondary to disease of the middle ear, and the method of operating for this septic condition has been fully shown, as also the symptoms which make the diagnosis probable. Case 1 was a boy aged nine years. He was admitted very ill with symptoms of thrombosis, and, in addition, internal strabismus was seen. An operation was performed, and a small quantity of pus was found behind the mastoid, and the mastoid was cleared out; offensive pus was found behind the lateral sinus, and a purulent clot was removed from the interior of the sinus. The internal jugular vein was tied on the following day. Rigors occurred after operation, and abscesses in the neck required to be opened. Recovery ensued. In Case 2 an operation was required on a boy aged six years within a month of the commencement of otorrhœa (the complication of an attack of scarlet fever); the symptoms of sinus thrombosis were very few, the chief localising sign being pain behind the ear. Fetid pus and clot were found in the lateral sinus, but not in the mastoid process. Pus could be pressed up from the neck into the wound. The internal jugular vein was tied on the following day. Suppuration in the right elbow and left hip, with spontaneous dislocation of the latter, caused much anxiety, but he ultimately recovered. In Case 3, that of a male aged nineteen years, pyæmia, manifested by the usual symptoms, with swelling of a shoulder, had been present for about three weeks. A septic clot was removed from the sinus and the internal jugular vein ligatured. The patient recovered, although several rigors occurred during the after-treatment. The shoulder-joint did not suppurate. In another case the operation was unsuccessful, the pyæmia proving fatal; the clot was above the point where the sinus was exposed: the jugular vein was not ligatured.

The cases of injury and disease of the abdomen which we have placed before our readers have been more numerous than usual, and show a continued advance in our methods of surgical treatment. Three of the most interesting resulted from direct injury. The first was caused at football by the head of an opponent which struck the patient in the region of the spleen. A large collection of fluid formed in the left side of the abdomen, which subsided after repeated aspiration; an effusion in the left pleura did not recur after the same method of treatment, and the man ultimately got well. In

Digitized by Google

the second case an abscess formed more than three weeks after a crush of the abdomen, and when this was incised fæcal matter was found in it. A fæcal fistula followed. The situation of the abscess, its contents, and the history of the case make it probable that there had been a rupture of the ascending colon. In the third case a man was shot in the abdomen, and the missile, a revolver bullet, entered an inch below and to the left of the umbilicus, and it was found at the operation that four coils of small intestine had been perforated. The eight resulting openings were sutured and the bullet found and removed. Recovery was perfect. Amongst the diseases of this region submitted to operation we may note acute diffuse suppurative peritonitis, caused by perforation of the appendix cæci, was successfully treated by abdominal section and free flushing of the intestines; also a case of rupture of hydatid cyst of the liver.

We have published no less than eight cases of operation for perforation of gastric ulcer, of which five recovered and three died. Of those which recovered the ages varied from nineteen years to thirty-one, and the duration of symptoms was from four to thirteen and a half hours. In four cases the median incision was employed, and in all these the ulcer was on the anterior aspect of the stomach; in one, where an oblique incision was made, the ulcer which had given way was on the posterior aspect and difficult to reach, and a second operation was undertaken later on account of similar symptoms, but the cause was not disclosed at the operation. In two of the cases thrombosis of a vein of the lower extremity appeared during convalescence. Of the three fatal cases the ages were twenty-one, thirty, and thirty-three years respectively, and the symptoms of perforation had existed for nineteen, nineteen and a half, and fourteen hours; the ulcers were in all of these cases on the anterior aspect. In most instances the openings were closed by Lembert's interrupted sutures, but in two the edges of the perforation were excised before the sutures were inserted; in one the peritoneum was drained and in another a glass tube was placed in the stomach. The series shows very strongly the dangers of giving morphia before the diagnosis is established, the great importance of early operation, and the necessity for thoroughly washing out the peritoneum. The causes of a fatal result were shock of operation, local suppurative peritonitis, and general suppurative peritonitis. The case of a girl aged twenty years is now historic, as a mass of hair weighing no less than 5 lb. 3 oz. was successfully removed through an incision in the anterior wall of the stomach. She had had attacks of vomiting for five years, and the tumour caused by the distended stomach was a large one at the time of operation. The largest similar masses previously removed during life were 2 lb. in one case and 30 oz. in another. We have for many years taken advantage of opportunities to publish cases of successful operation for intussusception, especially in infants below two years of age, as the disease is then very fatal, and the results of operation under the most favourable surroundings doubtful. In one case the child, a girl aged four months, was subjected to operation within twenty-four hours of the commencement of symptoms, but without any previous attempt at reduction by inflation or injection. The intussusception was easily reduced, and rapid recovery followed. In a second child aged twelve months symptoms had been present for nearly two days; attempts at reduction by manipulation, inflation, and injection failed, so the abdomen was opened in the middle line, and the intussusception reduced. The child was considerably collapsed afterwards, but recovered. We remarked on the importance of trying the simple and more successful methods before resorting to operation in intussusception when it can be treated within forty-eight hours of its commencement.

There have also appeared in the Mirror several important renal cases showing the similarity in symptoms sometimes produced by a tumour of the kidney and by a malignant growth in the colon over the kidney. Also the history of a case of congenital dilatation of both ureters in which right ureterotomy and left nephrotomy were performed in a newborn child. The child died ninety-four days after the operations from diarrhœa. The removal of a very large ovarian cyst from a girl aged sixteen years is an example of a tumour of most unusual size. The tumour weighed from eighty to ninety pounds, at least eleven pounds more than the emaciated body of the patient. The result was in every way most satisfactory. Cæsarean section was performed in the case of a woman aged twenty-six years, and resulted in saving the life of the child and the recovery of the mother. The latter was suffering from severe cancerous stricture of the rectum, for the relief of which inguinal colotomy had been performed some months before. The difficulties caused by the presence of an artificial anus close to the wound were serious, but skilfully overcome. We must here refer to a somewhat novel method of treatment (the first instance, we believe, in this country)—the formation of a permanent suprapubic opening in the case of a woman suffering from carcinoma of the urethra and bladder. The malignant growth was freely excised and the suprapubic wound then closed, urine being afterwards passed through the suprapubic opening into a portable urinal. The comfort of the patient was greatly increased. Tuberculous disease of the bladder has not been subjected to direct treatment through a suprapubic incision on many occasions in this country, and when it is disseminated throughout the mucous membrane, as in the majority of the six cases which we have placed before our readers, and is in an inaccessible position, it is difficult to understand how success can be obtained by less radical measures. When, however, the tuberculous process is localised, as in an ulcer which occupies a small portion of the mucous membrane, and the patient is a female, it may be possible to attack it through the urethra. Case 1. The patient was a female, aged twenty-two years with symptoms of three years' duration. No improvement followed local treatment during a period of months. A number of ulcers were found just within the orifice of the bladder; the ulcers which were accessible were scraped and then cauterised, some were only scraped and iodoform was rubbed in. The wound healed in three weeks. Case 2. This patient was a male aged thirty-three years, with symptoms of a few weeks' duration; in the trigone were four or five deeply congested patches about the size of peas, with slight ulceration on their surfaces, and in the surrounding mucous membrane a number of minute grey tubercles could be readily seen. These were scraped and iodoform applied; the bladder was drained for six

Digitized by Google

weeks. Case 3. This was a male aged twenty-three years who had symptoms for nearly three years. An irregular ulcer with jagged edges was found in the trigone; this was scraped and iodoform applied; the bladder was drained for six months. Case 4. A male aged fourteen years who had had symptoms for four months. A much thickened, congested, and warty patch was found on the right side of the trigone; the bladder was drained for three months, but the wound was open for seven months. The left kidney was removed for tuberculous disease. Case 5. A male aged forty-nine years, who had had symptoms for about six years. A thickened mass in the anterior wall with caseous material about the size of a florin was found and scraped; the bladder was drained for ten weeks. Case 6. A male aged thirty-one years, who had had symptoms for five months. The mucous membrane was vascular; there were numerous yellowish, raised patches, with granulation-like projections; the wall was sponged and the projections scraped with the finger-nail; the bladder was drained for a month. Very great benefit was received in all the cases, whilst in some sufficient time has elapsed to say that the patients have now recovered.

The Public Medical Services.

As regards the naval and military medical services there is not much to be chronicled as far as any changes in organisation or constitution are concerned. During the year that is past this country has had its military expeditions on a small scale, and other Powers have had theirs on a larger scale. At the moment of writing a British force is on the eve of advancing from Cape Coast Castle to the capital of Ashanti, and we are living amid the rumours of war, the mere possibility of one of which, notwithstanding that no one really believes in the occurrence of such an appalling calamity, has been sufficient to shake the world's money markets. One of the morals to be drawn from this excited state of the public mind—this condition of unstable equilibrium in which nations are living—is that the present is no time for neglecting the public medical services of this country. The COMMANDER-IN-CHIEF has emphatically dwelt upon the paramount importance of having a large and powerful navy, and he has told us that the great object he has in view is the perfecting of the British Army as a fighting machine. If we look back to the pages of THE LANCET for the past year or two it cannot be said, however, that in the opinion of many army medical officers their own particular branch of the service is perfect, or that sufficient pains are taken for its practical training, and for rehearsing in times of peace the duties which must fall upon it in times of war. Still, greater efforts are being made from year to year towards attaining this end. This empire may be said to have tentacles spread out everywhere, and no political storms and currents taking place in the world's history can fail to affect us in some measure. It cannot be alleged that our small campaigns and expeditions since the time of the Crimean War have been invariably designed, provided for, and carried out with the sanitary and medical success that was attainable, but the progress which has been made during the interval has nevertheless been enormous. We have always contended that what is best for the public is best for the services themselves. There is no finality to progress in efficiency. Unhappily, we live in times when all civilised and many semi-civilised nations are equipped with arms of precision and all the latest inventions, and the advances made in these respects render modern war a very different thing to what it was. Our pages during the past year have contained many observations on the effects of the Lee-Metford rifle and other arms, and the address of Sir WILLIAM MACCORMAC, the President of the Surgical Section of the British Medical Association, at its late meeting gave an excellent epitome of our knowledge of these modern weapons in relation to the surgery of war. The size of belligerent armies nowadays and the greatly increased number of wounded are factors which tax the organisation and powers of the largest and best medical services in the world, and it is quite conceivable that these may prove in the future more than any medical force can adequately cope with. It is obviously important, therefore, that the military and naval medical services should be the best that selection and training can make them. The first Ashanti war, under Sir GARNET WOLSELEY, in 1873 was called an "engineers' and doctors' war," and was well managed, and there is no reason why the present campaign should be less successfully conducted in a medico-sanitary respect, with which we as medical journalists are only concerned. During the past year the Indian Government has had its Chitral campaign, with the heroic energy and brilliant marches of the relief expedition over the Shandar Pass, some 12,000 ft. high and only ten miles distant from a mountain peak with an altitude of 21,000 ft., and other dramatic situations and military achievements. In this expedition, where all did excellently well, the Indian and British Medical Services rendered most valuable aid. Several members of the Indian medical department—notably Surgeon-Major ROBERTSON and Surgeon-Captain WHITCHURCH—rendered distinguished services in the siege and relief of Chitral. The latter officer exhibited conspicuous bravery during a sortie from Chitral in March last, for which he received the Victoria Cross, and the former the titular distinction of a Knight Commander of the Star of India, in recognition of the services he rendered prior to and during the siege of the hardly-pressed garrison of Chitral. As we have said, other countries have had their wars and expeditions also during the past year. The French expedition to Madagascar, which was really a remarkable military achievement, was unhappily attended with large mortality-, sick-, and invaliding-rates attributable to climatic causes and, we fear, largely also to want of proper provision and hygienic arrangements. In no campaign, probably, has the French soldier exhibited higher or more soldier-like qualities than he did in Madagascar—brave, patient, and enduring under difficulties, hardship, and disease, and, according to all English correspondents, humane in his conduct towards the natives. The Chino-Japanese war brought to light the remarkable qualities of the Japanese, their aptitude for organisation, and the singular knowledge they displayed of modern scientific methods of warfare and of surgical art and appliances and field hospital work. Their weak point was sanitation, of which they did not seem to have an elementary knowledge—at any rate, in the earlier part of the war. It would be very interesting to have a medical and surgical history of this war, with the

Digitized by Google

statistical results of the methods adopted by the Japanese. As regards the Italians in Abyssinia, beyond the fact that they have recently had a bad reverse, and that the Italian officers behaved with uncommon gallantry and devoted courage, we know but little. A very large reinforcement had been sent by the Italian War Office to Abyssinia, and we shall probably soon learn the results of Italian surgery in the field and the work of its medical service in that country.

Death has been very busy of late in the senior retired ranks of the Army Medical Staff. Amongst those who have passed away were Sir THOMAS CRAWFORD, K.C.B., the late Director-General, Sir THOMAS LONGMORE, C.B., the late well-known professor of military surgery at Netley, and other officers respectively noticed in our obituary columns at the time of their decease. The year that is to follow will probably see many changes in medico-sanitary matters in India. The term of service of the present Director-General of the Army Medical Staff is drawing to a close, and army medical officers will soon be inquiring as to his probable successor and as to the changes that will be brought about in 1896 under the newly-appointed Commander-in-Chief at the head of the Army and a forthcoming Director-General of their own service.

Chemistry.

The year 1895 will be ever held memorable in the annals of chemistry. It has seen the recognition of another constituent of the air and the discovery of an element existing upon the earth which had formerly been supposed to exist only in the sun. If argon had not been a constituent of the air, and helion not an element the existence of which had been indicated in the sun, the discoveries would have been on no higher level than those which, occurring now and again, consist in the mere addition of bodies to the list of presumably new elements. No discovery of rare earths or of new metals in rare earths is comparable in importance to the discovery of argon and helion. We have yet to learn the properties and functions of argon, but its existence had not been discovered long before it was the means of leading to a discovery which startled the astronomic world. We refer to the extraction from certain minerals by Professor RAMSAY of a gas which proved to be identical with the helion of the sun, giving lines in the spectrum corresponding exactly with those of the sun's chromosphere. Since this announcement was made the subject has been attacked with extraordinary energy; more minerals have been examined and more fresh results have been obtained, and *inter alia* Professor NORMAN LOCKYER has shown that the gas from the mineral cléveite is one of complex origin, and spectroscopic analysis indicates distinctly that several lines are closely related to the solar and stellar phenomena. "We appear to be in the presence," he observes, "of the *vera causa* not of two or of three but of many lines which so far have been classed as unknown by students both of solar and stellar chemistry, and if this be confirmed we are evidently in the presence of a new order of gases of the highest importance to celestial chemistry, though perhaps they may be of small practical value to chemists, because their compounds and associated elements are for the most part hidden deep in the earth's interior." There seems to be little doubt that neither argon nor helion is an element, and each day we may expect new announcements of the isolation and separation of single constituents from them both. Such has been the brilliance of the results of Lord RAYLEIGH and Professor RAMSAY'S researches that the steady and, nevertheless, laborious work of investigations in other fields has been to some extent lost sight of. Their results have been dimmed by the strong radiance of the premier discovery. We referred, for instance, last year to the isolation of a new element from bauxite by Dr. R. S. BAYER, who has since obtained more precise information in regard to it. This new element appears to be related to the tellurium and vanadium group of metals, and its salts yield a series of perfectly distinct and beautiful colour reactions with the usual reagents. Dr. FRANK CLOWES has drawn some important conclusions in regard to the respirability of air in which a candle flame has been burnt up to its point of extinction. He finds that such air is safely respirable, but an atmosphere which extinguishes a coal-gas flame appears to approach closely to the limit of respirability as far as the proportion of oxygen which it contains is concerned. Hence the coal-gas flame appears to be a more trustworthy indicator of respirability than the flame of a candle or oil lamp, which should be discarded as absolute tests of the respirability of air, for by adopting these tests a person may be deterred from entering an atmosphere which is safe and respirable, and from rendering services of a humane or urgent character. Calicum carbide, since its discovery, has been made in commercial quantities by fusing lime and carbon together in the electric furnace. This substance yields pure acetylene gas on moistening with water, which has an illuminating power of 240 candles—that is, fifteen times greater than the Parliamentary standard. It has been proposed to use calcium carbide as a means of portable light, and to employ it as a gas for illuminating purposes, or for the enrichment of gas of low illuminating value. An interesting note on the active constituent of the pellitory of medicine by Professor DUNSTAN showed that the activity of the plant (Anacyclus pyrethrum), usually ascribed to a resin, is due to a crystalline, intensely active substance present in the resin which has been named "pellitorine." Progress in "vital chemistry" has been slow. We are yet far from understanding how it is that nature produces molecules of a highly complex character without, as Professor MELDOLA put it at this year's meeting of the British Association, the use of strong reagents and at ordinary temperatures. Syntheses of complex organic compounds with long sounding names have been constantly accomplished by the chemist as before, but the process of the natural building up of molecular structure is still surrounded with obscurity. Professor MELDOLA asks, Is there any evidence that the 180 substances successfully synthesised in the laboratory are produced in the organism by a direct process of building up? Is not the opposite view possible, and may not these substances, from the simplest to the most complex, be products of the degradation of still more highly complex molecules? What is more complex in structure than protoplasm, which is present in, and forms part of, the organism from the very beginning of its existence—from the germ to the adult—and onwards to the end of the vital process? On the other hand, the chemists' equivalent for protoplasm, the primordial matter out of which the various elements have been fashioned, the protyle, is

Digitized by Google

necessarily assumed to be the simplest form of unorganised matter. In spite of the great and striking discoveries of the year we still see through the glass darkly as to the origin of life, and not even the brilliant discoveries of Lord RAYLEIGH and Professor RAMSAY have thrown so far any light on the question as to what the atom is: whether, as Lord SALISBURY has said, it is a movement or a thing, or a vortex, or a point having inertia; whether there is a limit to its divisibility, and, if so, how that limit is imposed; and whether the long list of elements is final or whether any of them have any common origin. Still must the truth ever be sought: though every fresh discovery appears to bring us not only no nearer to it, but sometimes further off than before, each one must surely be a piece which will some day be found to fit in when the problematic whole is made up.

Epidemiology and Public Health.

Taking 1895 as a whole it cannot be described as an unhealthy year. It is true that, with the intense cold of January, there was a distinct increase in the amount of death amongst people over sixty years of age, and that epidemic influenza once again added to the mortality at advanced ages. So also, following on the comparative drought of August and September, and in connexion with the unusual heat of the latter month, there was an excess of death amongst infants. This latter was mainly due to epidemic or autumnal diarrhœa, the deaths from which were more numerous during the third quarter of the year than they had been for over ten years. But when all this is said the general death-rate has not been in any way excessive. One disease, however—namely, diphtheria—has maintained an unusually high death-rate throughout all phases of temperature, rainfall, &c., ever since the beginning of the year; and the ordinary increase which annually sets in about the middle of September has been almost altogether exceptional in so far as the amount of death is concerned. Indeed, during the eight weeks ending Dec. 7th, 1895, the weekly number of deaths from diphtheria in London ranged from 61 to 76, the mean being no less than 68. This disease seems to be passing beyond control, and this being the case we cannot but regret that more use is not made of the antitoxin serum. We are not here concerned with its use as a remedial agent, but we wish that its power to confer immunity against attacks in households already infected had been put more frequently to the test. The process of injection, if properly carried out, is trivial and harmless, and even if the protection afforded turned out, as some suppose, to be very evanescent and of comparatively short duration, it would be well to know if, by its use, protection, however limited, against this fatal disease is to be obtained.

Small-pox at one time appeared to be threatening the metropolis and certain other towns in England. In London the number of inmates of the small-pox hospital ships became exceptional, but before the advent of the late autumn, when increase in this disease is most to be dreaded, the epidemic had largely subsided. Indeed, the whole history of small-pox in the metropolis, since the sick have been removed down the river instead of being aggregated in hospitals placed in populous centres, has been very remarkable. The latter system was associated with constantly recurring epidemics in London; the system now in vogue seems to lend itself to a fairly rapid extinction of each individual threatening of an outbreak. The relation that exists between vaccination and small-pox compels us once more to express our profound regret that the Royal Commission on Vaccination, appointed as far back as May, 1889, has never yet given the slightest indication as to the nature of the conclusions at which its members have arrived with regard to the value of that operation as a means of controlling and preventing small-pox. But, on the other hand, the inexplicable delay, during which three members of the Commission have died, has brought about a general condition of neglect in the matter of vaccination which no recommendations or advice of the Commission can remedy under many years, if, indeed, at all.

Happily, we have had no prevalence of cholera in England this year. It is true that certain fatal attacks of a disease which was clinically deemed to be cholera occurred at Great Grimsby during one period of the summer, but bacteriologically the cases were held to differ from Asiatic or true cholera, and that test is, for the moment, looked upon by local authorities and others as settling the question. But the disease still prevails in Europe and in other parts of the world under circumstances that involve risk of danger to this country. Russia, which still exports her aliens largely through our ports, has had this year some 27,000 cases and some 10,000 deaths from cholera. The principal provinces affected have been Volhynia, Podolia, and Kieff; but more recently the disease has appeared in the north, including St. Petersburg. In Galicia there was a fresh autumnal outbreak, and some 250 deaths have already resulted from it. Turkey in Asia has again been a seat of the disease, and the number of deaths there can hardly be less than 3000. A fresh importation has also come from the East. Quarantine restrictions have once more failed, and cholera reached Mecca and Jeddah. In connexion with the returning pilgrims the disease got access to Egypt, especially in the neighbourhood of Damietta, where cholera has lingered for some time; it also reached Tangier and Morocco, and it is in these newly affected places that a fresh introduction of infection from the East is likely to be a cause of distinct anxiety when the warm weather of 1896 sets in. Indeed, we must again, for another year, urge upon sanitary authorities and sanitary officers to be vigilant, and to endeavour to maintain in their districts such a standard of public health and sanitary conditions as will enable them to extinguish at the onset any beginnings of cholera or of any disease having etiological and clinical relations with that disease.

There was no noteworthy sanitary legislation during 1895. It had been intended that last year should have seen the end of our old quarantine laws, but under the special Parliamentary conditions the Bill for repealing those laws had to stand over until next session. We shall welcome such repeal, for it will fortify our position in claiming abatement of quarantine restrictions imposed by other countries and by our own colonies. Whilst referring to this subject we would recall the fact that the Paris Convention, which was signed by the British delegates early in 1894, subject to certain definite reservations,

Digitized by Google

has never been ratified. The original date, however, for ratification has now passed, and we can only attribute the failure to the unwillingness of other nations to forego the proposals made in such matters as the definite establishment of new quarantine stations in the Persian Gulf. The result may also, in part, be due to the disinclination of certain nations interested in the pilgrim traffic to accept the limited offer as to increase in deck space to be allotted on pilgrim ships which was made on behalf of this country. Indian views prevented our acceptance of the French proposal, which could not be objected to on purely sanitary grounds, and our offer to meet France and other nations half-way is still resented by some of the native population. In the meantime everything relating to the Mecca pilgrimage and to the sanitary circumstances associated with it is at a standstill. It is to be hoped that at the close of next year we may have been able, with the coöperation of other Governments concerned, to make some substantial advance towards securing conditions which shall prevent this annual religious feast from becoming so fertile a source of disease and death to a vast number of our fellow-subjects in India.

"*The Battle of the Clubs.*"

One of the most satisfactory facts in the history of the profession in the course of the year has been the indication in various localities of a development of *esprit de corps* leading to the formation of strong local organisations and the assertion of the most obvious professional rights. This movement—for it is nothing less—began seriously in Cork in the year 1894, and even earlier, and it may now be said to be felt more or less generally. We have long thought that there was something grossly wrong in the position of the profession in the great centres of industry—that its services were too lightly recompensed and often too easily obtained for nothing. We thought that the time had come to institute some systematic inquiry into the question as it presents itself in different towns. We appointed for this end a gentleman of much experience in such pursuits, of fair judgment, without prejudice, and of good literary and descriptive ability. The result is a series of papers in the course of the year headed "The Battle of the Clubs," which give a better account of the system on which clubs are conducted, the opinion held by the profession, and its efforts to raise the whole standard of club service and of payment and respect for medical officers than, as far as we know, can be found elsewhere.

There is one other feature of these descriptions of the club system which should command for them the attention of the members as well as of the medical officers—we mean their obvious impartiality. The writer has not hesitated to record the opinions of medical men or of laymen interested in this subject, which seemed to throw the blame for medical aid and similar sweating institutions on the medical profession. His obvious business was to record such facts or opinions as were entitled to consideration. For example, at Hull several medical men told our Special Commissioner that "some club officers, by their neglect of club patients, had brought the creation of friendly societies' dispensaries on themselves." At York the President of the medical society expressed the opinion that the profession by its overcharges had driven people into clubs, instancing a servant girl who had received a bill for £15 and a gentleman with an income of £200 a year who had received a bill for £30. We are not accepting these statements as a fair account of the origin of clubs or of the entrance into them of those who can afford to pay, but we give them as illustrations of the impartiality with which our Commissioner has reported different views of this difficult question. The result of his labours is to be found in his account of the Battle of the Clubs in Brussels, Portsmouth, Eastbourne, Lincoln, Great Grimsby, Bexhill, Hull, York, and Northampton. He has not yet completed his labours, but the above reports are a striking proof of the fact that the profession has at length awoke to a sense of the importance of united local action in vindication not of its rights merely, but of the reform that is necessary in the conditions of medical attendance on the working classes.

The time has not come for dogmatising on details, such as the expediency of a wage limit, or the exact figure at which it should be placed, the wisdom of including all the willing medical men of a given place on the staff of a dispensary or of limiting the numbers, the advantage of a dispensary system created and managed solely by medical men, or by the representatives of friendly societies, or by some joint committee. The interest of the reports is in supplying information of the actual condition of things in the different towns. A few facts may be noted at once, which to those who have not pondered on the subject will appear incredible. The low terms on which medical men have been remunerated is the first. At Hull, in the dispensary started by six lodges of Oddfellows, where an experienced medical man estimated that 20 per cent. of the members could pay the ordinary fees which a medical man would charge a working man, a whole family is attended for 12*s.* 6*d.* Taking the figures supplied by the Friendly Societies' Medical Alliance, this dispensary gives for each consultation with its medical officer the sum of a very small fraction above seven farthings. At Portsmouth, where the wages of working men have advanced 10*s.* a week, the whole standard of club remuneration has been demoralised by the example of the Portsmouth Medical Benefit Society, which takes in all the members of the family at the handsome sum of ½*d.* per head per week. We will not multiply instances of such twopenny-halfpenny treatment of the medical profession, which almost tempts us to fear that as the British workman has grown in wealth he has receded in generosity and the sense of justice.

We hasten to notice a more satisfactory fact brought out in these reports—the realisation by the profession that things have come to such a pass that they must be amended, and that there is only one way of procuring this amendment—viz., the union of the profession in different localities to enforce reasonable terms and to make it impossible for strangers to come in and interfere in what is essentially a domestic matter. One of the most striking illustrations of this union, and one of the first, reported in a very interesting communication by our Commissioner, was in the case of Brussels, where the same evils are found and are being met with admirable resistance. The medical men.

Digitized by Google

formed themselves into a syndicate, not so much to obtain more money, as to exclude comparatively rich men from the benefit societies. Cases were cited of men in such societies earning £1000 a year. The union of the profession was so effective that the medical chief of those who supplanted the men who resigned their ill-paid posts on the Mutualist Federation of Clubs had at length to apologise and to resign. At Eastbourne, perhaps, the union of the profession has been carried to the highest point, the whole resident medical men combining to form the Eastbourne Medical Provident Association, which every medical man is free to join. The association has practically gained its point, which was to overthrow the National Medical Aid Company, Limited—one of those commercial companies which seek to commercialise medical attendance, and which in doing so degrades medical service and those who render it. At Portsmouth the union of the profession has had a great triumph. All the men in practice signed an agreement not to oppose any gentleman who acted in accordance with the general consent of the profession concerning any public appointment. The holder of certain clubs declined to attend juveniles and infants for less than 4*s*. a head. Four strangers tendered at a lower figure. All the local men supported the medical officer, and the tactics of unanimity prevailed. He was reappointed. At Bexhill the Eastbourne example has been followed. Mr. JACKSON of Plymouth, President of the Incorporated Society of General Practitioners, informs us that the men of Devon and Cornwall also are following the example of Eastbourne.

We do not advocate any inhumane action towards the really poor, but we expect all practitioners to join in the "Battle of the Clubs" and secure a proper recognition of the value of medical services. So, more or less, in some other places. We must not write as if the "Battle of the Clubs" had been everywhere fought and won. The fight is only beginning and in some places is very much needed indeed. In Lincoln the Medical Aid Association includes a large number of men of independent means—ex-mayors, &c.—who are quite willing to take their medical attendance for 3*s*. 6*d*. a year—a sum for which they would not get a good errand boy for a week. At Hull, too, the movement is very weak-kneed. At York, though there is a good understanding between the medical society and the medical officers of the friendly societies, it is not denied that many members of the Friendly Societies' Dispensary could pay easily two or three pounds a year to the profession, though they now pay only 12*s*. 6*d*. It is vain for medical men to delude themselves with hopes of help from outside for the settlement of such questions. They have the means of helping themselves, as the cases of Brussels, Eastbourne, and Portsmouth show. They would be much more respected by the public if they asserted these rights. Central or metropolitan associations can do something, and ought to do more than they do in this "battle." But it is essentially a local one. One word must be said as to the duty of consultants in this matter. They must clearly recognise that they have their obligations to the profession. It is complained that in some cases a consultant is true to his brethren, but becomes discouraged on finding that others have adopted quite a different course of action.

The Royal College of Physicians of London.

The proceedings of the Royal College of Physicians of London during the past year have only been marked by one event of importance, and that was the decision arrived at at a special meeting on Oct. 24th to decline the petition of those interested in the medical education of women to admit women to the examinations for the licence. The decision on this occasion was closer than anticipated, showing 59 votes in favour of rejecting the petition against 50 in support of it. Otherwise the College has pursued the even tenour of its way, with no very noteworthy incidents. The munificence of Dr. HERMANN WEBER has enabled the College to institute a triennial prize of 150 guineas for essays on the subject of tuberculosis, the prize being termed the Weber-Parkes Prize, for it has been founded by Dr. WEBER in memory of his friend the late Dr. E. A. PARKES. The first award is to be made in 1897, and the subject chosen for competition is "The Means, Prophylactic or Curative, deemed by the Author to have Value in the Control of Tuberculosis, especial Regard being had to their Application to Human Tuberculosis." The regulations for the examinations for the Diploma of Public Health have been subjected to revision; and the decision of both Royal Colleges to dispense with the proposed Third Examination in the new five years' curriculum has met with general approval. At the meeting at which this subject was discussed it was recommended that pharmacology should form part of the examination in medicine, instead of standing alone as a separate subject. The Pharmacopœia Committee presented a report of suggested alterations in the Pharmacopœia which was adopted by the College. The College was represented at deputations to the late Prime Minister and to the Duke of DEVONSHIRE upon the London University question by the President, the Registrar, and Dr. ALLCHIN, to whom the duty of speaking on behalf of the College was assigned. During the meeting of the British Medical Association a conversazione was given by the College and was numerously attended. Sir J. RUSSELL REYNOLDS has been re-elected President, and the various lectures were delivered as follows: the Goulstonian, on the Suprarenal Bodies, by Dr. H. D. ROLLESTON; the Milroy, on the Natural History and Affinities of Rheumatic Fever, by Dr. NEWSHOLME; the Lumleian, on the Diagnosis, Prognosis, and Prophylaxis of Insanity, by Dr. G. F. BLANDFORD; the Croonian, on the History of the Respiration of Man, by Dr. MARCET; the Bradshawe Lecture, on Some New Vaso-dilators, was delivered by Dr. BRADBURY, and the Harveian Oration by Dr. CHURCH. The Baly Medal was awarded to Dr. W. H. GASKELL, F.R.S., and the Murchison Scholarship was gained by Mr. MACVICAR of Edinburgh University.

The Royal College of Surgeons of England.

Reform at the Royal College of Surgeons of England advances slowly; meetings of Fellows, of Members, and of Fellows and Members have been instituted, but they have not always been utilised to their full extent. At the annual general meeting of Fellows and Members in November resolutions were passed, practically unanimously, in favour of

Digitized by Google

obtaining an amended charter, which should contain provisions—(*a*) that no alterations in the constitution and external relations of the College should be effected without the consent of the body corporate; (*b*) that the present annual general meeting be made statutory, and that the report of the Council be submitted for formal adoption; and (*c*) that the Members of the Council be increased to thirty-two, and that eight of these, who may be Members, shall be elected by the Members only, provided always that no Member who has not been a Member for twenty years shall be eligible for a seat on the Council. At the January meeting of the Fellows there was some difficulty in obtaining a quorum, and the Council having declined to test the opinion of the general body of Fellows as to the advisability of any change in the mode of election of the President, Mr. HERBERT PAGE, on behalf of the Society of Fellows, communicated the result of a canvass amongst the Fellows, which showed a large majority in favour of some change. The July meeting consisted merely of a statement by the President that certain changes in the by-laws had been approved by the HOME SECRETARY, and that the Council had appointed a committee to receive deputations from the Fellows. As no notice had been given of any resolutions nothing more was done. In February the President, Mr. J. WHITAKER HULKE, F.R.S., died, and Mr. CHRISTOPHER HEATH was elected in his stead, and re-elected in July. Mr. REGINALD HARRISON and Mr. PICKERING PICK were appointed Vice-Presidents. At the election to the Council in July there were five vacancies and nine candidates. Mr. WILLETT was re-elected, and Mr. F. TREVES, Mr. H. T. BUTLIN, Mr. ALFRED COOPER, and Dr. WARD COUSINS were elected. For this election voting papers were sent for the first time to all Fellows, and they were receivable at the College up to the time of the commencement of the election; altogether 621 Fellows voted. A memorial was received by the Council from the London School of Medicine for Women, asking for the admission of the students of the school to the examinations of the College. The matter was referred to the annual meeting of Fellows and Members, and the majority voted against the admission of women, though the numbers were nearly equal. When the matter again came before the Council they expressed their approval of the admission of women, but regretted that at present it was not possible for them to accede to the requests of the memorialists. The pecuniary position of the College is not satisfactory, as its income is falling steadily year by year, and there is no indication of any likelihood of improvement. The committee appointed to consider the advisability of having a practical physiology examination for the first examination for the Fellowship have reported against any change.

Meetings of the General Medical Council.

The General Medical Council held two meetings as usual, one in May, the other in November. The later meeting took place in the Royal College of Physicians of London, as the premises of the Council, now owned by them, were undergoing reconstruction. At the May meeting the presence of Sir JOHN SIMON was much missed. But his place as Crown nominee was well filled by Dr. THORNE THORNE, who soon took a useful share in the work of the Council. A lively discussion took place in May on the best way of giving due importance to the views of medical practitioners, as distinguished from pharmacists, in the preparation of the new edition of the Pharmacopœia. The President, Sir RICHARD QUAIN, was very happy in his efforts to retain much of the machinery that worked well in the case of the present Pharmacopœia while accepting suggestions for securing the full assistance of medical experts. It is understood that all parties are working well and harmoniously. A still more lively subject of discussion at the May meeting was that of the Midwives Bill, then before Parliament, and sent down by the Privy Council for the consideration of the General Medical Council. The Council referred the Bill to a committee which had been previously appointed, and on its report a full discussion took place. The Council also received a deputation from the Lancashire and Cheshire Branch of the British Medical Association of those opposed to such legislation. The result was that the Council made various alterations in the Bill, chiefly one in its title—viz., "That the title of the Bill be amended so as to read 'A Bill to promote the better training of women as midwives and midwifery nurses, and for the compulsory registration of them as such.'" In other words, the Council did not depart from its traditional views on this subject, but emphasised its opinion that the women to be registered must be registered under a title that would make clear their non-medical character—in fact, that they were nurses and in no sense medical practitioners. A very important act of the Council at its May meeting was to affirm the insufficiency of the conjoint examination of the Apothecaries' Hall of Dublin and the Royal College of Surgeons in Ireland, and to resolve on a representation to this effect to the Privy Council. The November meeting is too fresh in the recollection of the profession to need much notice here. The subject of the constitution of the Council and the increase of the number of direct representatives was raised by Sir WALTER FOSTER, and seconded by Mr. WHEELHOUSE. The Council rejected the proposal to refer the matter to a committee by a majority of 20 to 7. It has never had any sympathy with the principle of direct representation, though highly civil to the direct representatives. It is satisfactory to note that, on the motion of Dr. GLOVER, seconded by Dr. THORNE THORNE, the Executive Committee was instructed "to revert to the question of the disciplinary functions of the qualifying medical authorities and of the General Medical Council, and to report to the Council at its next meeting on the best means of further defining and confirming these functions and bringing them into harmonious and efficient coöperation." On the thoroughness with which this duty is discharged by the Executive Committee much of the discipline of the profession in future will depend. The Council was occupied chiefly in the discussion of the specific recommendations by the Examination Committee arising out of the consideration of the reports of the inspector and visitors of the final examinations, and in the discussion of the report of the Public Health Committee and of the recommendations therein contained. The chief drift of these recommendations was to emphasise and confirm the

Digitized by Google

determination of the Council to maintain a high standard of examination for any diplomas or degrees in Public Health. Dr. THORNE THORNE'S able management of the report made it clear that there will be no abatement in the demands of the Council on this subject. The subject of practical instruction in midwifery was referred to the Education Committee, which, let us hope, will effectually condemn the absurd regulation of the Council on this matter. The Apothecaries' Society of England, through its representative, Mr. BRUDENELL CARTER, intimated to the Council its wise determination to discontinue its examination in Arts from the end of the current year. The Council by resolution instructed the Penal Committee to inquire into the cases of persons offending under Section 40 of the Medical Act, and *where it sees fit* to instruct the legal advisers to proceed against such persons. The subject of examinations by the Apothecaries' Hall of Dublin again occupied the serious attention of the Council in two ways. A communication from the Privy Council sought information as to the length of the continuance of the examinations of the Hall conjointly with the Royal College of Surgeons in Ireland. The Council replied that all existing claims of candidates who have already passed a part of these examinations should be exhausted within six years from the present time, the bodies in question being prepared to meet their claims. The Council reaffirmed its opinion of the inefficiency of the examinations, and it declined to comply with the request of the Apothecaries' Hall to appoint surgical examiners. It will be curious to see whether the Hall will now apply to the Privy Council to procure the appointment of such examiners, which the Council refuses to appoint of its own motion. Sir JOHN BANKS maintained that the Hall supplied a want in Ireland; but the numbers of those who seek this qualification seem to show that there is not a great demand for Irish apothecaries. As an alternative Irish students must obtain the costly diploma of the Irish Colleges or go elsewhere for examination. The November session was the fifty-ninth session of the Council.

British Medical Association.

Under the distinguished presidency of Sir JOHN RUSSELL REYNOLDS, President of the Royal College of Physicians of London, the sixty-third annual meeting of the British Medical Association was this year held in the metropolis. The Presidential Address took the form of a masterly review of the state of medicine at the present day compared with that of the time of the ever-to-be-lamented Dr. PARKES, who, twenty-two years ago, when the Association last held its meeting in London, under the able presidency of the late Sir WILLIAM FERGUSSON, delivered the address in Medicine. The able addresses in Medicine and Surgery at the present meeting were delivered respectively by Sir WILLIAM BROADBENT and Mr. HUTCHINSON, and the excellent address in Physiology was given by Professor EDWARD A. SCHÄFER. The introductory addresses in nearly all the sections showed evidence of careful thought and an intense desire to improve and help forward a profession which, founded as it is on an altruistic basis, must ever command the respect and support of all who have at heart the good of humanity. Dr. WILKS'S important opening address in the Section of Pathology will go far to increase the attention which is being paid to the study of morbid anatomy, and Sir WILLIAM PRIESTLEY'S presidential address in the Section devoted to Obstetrics and Gynæcology was the subject of much attention and some criticism. Looked at as a whole the sixty-third annual meeting of the British Medical Association may be said to be one of the most, probably the most, successful meeting the Association has ever held. All who took part in its organisation are to be congratulated, and the votes of thanks accorded to Mr. ANDREW CLARK, Dr. ISAMBARD OWEN, and Mr. H. T. BUTLIN at the concluding general meeting were well deserved. Those, too, who organised the various excursions and ministered to the enjoyment of the visitors deserve nothing but praise.

The University of London.

In January, 1894, the report of the Gresham Commissioners, under the chairmanship of Lord COWPER, was issued; but it led to but little practical action during that year, except to prove the existence of a marked difference of opinion in the University of London. In January, 1895, the movement for reconstitution was revived, and Lord ROSEBERY received two deputations on the subject. The first deputation of teachers and others who were in favour of the scheme received his favourable support; whilst the second, which consisted of graduates who were opposed to it as depriving Convocation of the most important of its rights—viz., that of a veto on any new charter—received but faint encouragement. Lord ROSEBERY, however, said that the Government would be bound "to consult very largely the vote of Convocation, whenever it is taken," on the question of appointing a Statutory Commission to carry out the scheme of the Gresham Commissioners. On the 22nd of that month a meeting of Convocation took place, and 421 members were present. Dr. SILVANUS THOMPSON moved, and Dr. ALLCHIN seconded: "That Convocation is of opinion that there should be one university in London, and not two; and that the interests of higher education will be best served by such an enlargement and reconstruction of the existing university as will (while retaining its existing powers and privileges, and without interfering with the efficient discharge of its present duties as an examining body for students from all parts of the British Empire) enable it to promote learning, scholarship, and research as a teaching university for London." It was moved, as an amendment, by Mr. BOMPAS, and seconded by Dr. NAPIER: "That all the words in the motion after the word 'That' be omitted, and the following words be added: 'In the opinion of Convocation it is essential that in any enlargement or reconstruction of the University of London, its existing powers and privileges should be retained unimpaired, the efficient discharge of its present duties should not be interfered with, and the high standard of its degrees should be maintained.'" Two hundred and six members voted for the original motion, and 174 against. On a second motion as to the powers of the Statutory Commission an amendment was moved that the scheme did not contain adequate securities for external students and for keeping up the high standards of the degrees. One hundred and thirty-three voted for the amendment, and 157 for the original motion.

On May 14th the next meeting of Convocation was held, and

Digitized by Google

a most curious difference as to the opinion of the University on the question was displayed. Mr. BOMPAS endeavoured to get the resolutions rescinded which had been passed in January, but he was defeated by 238 votes against 116. At the same time an election for a vacancy on the Senate was proceeding. Mr. COZENS-HARDY, as the chairman of the committee in favour of the scheme of the Commissioners, was brought forward by one section, and he was opposed by Dr. NAPIER, who was nominated by those who objected to the scheme as over-riding the privileges of Convocation. One thousand two hundred and thirty-one graduates supported Dr. NAPIER, who was elected, whilst 738 voted for Mr. COZENS-HARDY. It was therefore apparent that whilst those graduates who attended the meetings of Convocation desired a reconstitution of the University, those who resided in the provinces when permitted a proxy vote showed that they were quite opposed to the schemes. The next step was the introduction in the House of Lords on May 9th, 1895, of Lord PLAYFAIR'S Bill to carry out the recommendations of the Gresham Commissioners. The operative clause in the Bill, which was a very short one, was as follows:—

1. The Commissioners shall make statutes and ordinances for the University of London in general accordance with the scheme of the report hereinbefore referred to, but subject to any modifications which may appear to them expedient after considering any representations made to them by the Senate or Convocation of the University of London or by any other body or persons affected.
2. In framing such statutes and ordinances the Commissioners shall see that provision is made for securing adequately the interests of non-collegiate students.
3. All such statutes and ordinances shall be laid forthwith before both Houses of Parliament, and shall come into operation on the expiration of forty days after they have been so laid, and shall have effect as if enacted by this Act, but shall be subject to alteration in manner provided by such statutes and ordinances.

The resignation of the late Government settled the fate of that Bill, and it never passed beyond the first reading stage in the Upper House, but the Duke of DEVONSHIRE has recently plainly intimated what would have been the result if it had been pushed forward. "I am quite sure that if Lord PLAYFAIR'S Bill had in the last Parliament reached the House of Commons it would have encountered a considerable amount of opposition." When the addresses of the candidates at the general election were issued most of the graduates were astonished at the position adopted by Sir JOHN LUBBOCK. He not only supported the existing rights of Convocation as to a veto, but stated that it would be his utmost endeavour that the decisions of a Statutory Commission should be submitted, not merely to graduates in Convocation assembled, but that absent graduates should have a proxy vote, as in elections for a Fellow on the Senate or a Member of Parliament. This has materially altered the position of the question. On the one hand, Lord PLAYFAIR'S Bill would have deprived Convocation of its power of veto; on the other hand, Sir JOHN LUBBOCK insists that every graduate should be able to exercise his right, even by a proxy vote, and not by a personal attendance as is the constitutional method under the existing charter.

On Nov. 29th a large deputation of representatives interested in the Gresham scheme, who were introduced by Lord KELVIN, a member of the first Commission, waited upon the Duke of DEVONSHIRE as Lord President of the Privy Council. They submitted to his Grace a resolution which had been passed at a meeting of those interested at the University of London on the 21st: "That the Government be requested to introduce, at an early date, a Bill, similar to Lord PLAYFAIR'S London University Commission Bill, 1895, appointing a Statutory Commission to carry out the recommendations of Lord COWPER'S Commission, but with an added clause giving [in accordance with precedent Acts of similar tenour] to all institutions or persons directly affected by any statute or ordinance proposed by the Statutory Commission a right of appeal to the Privy Council for the disallowance or alteration thereof, previous to such ordinance being laid before Parliament for confirmation." The right of appeal to the Privy Council was not contained in Lord PLAYFAIR'S Bill. The reply of the Duke must have greatly surprised the delegates, and was far from encouraging to their hopes. He expressed his anxiety for the external students, whom, he stated, were not represented on the deputation, and thought "that it was a somewhat strong proceeding that a change in the constitution of the University should be imposed upon it without allowing Convocation to exercise their right" of veto. Obviously, the Lord President of the Council supports Sir JOHN LUBBOCK in his opposition to Lord COWPER'S scheme so far as the rights of Convocation are concerned, and would favour an extended system of taking the vote. His Grace's suggestion for a unanimity in the University of London itself is futile, for the amendments recommended by the dissentients to the scheme go to the root of the question, and are fatal to the main principles laid down by the Commissioners. As we said on the 7th inst., "the movement has arrived at an *impasse*, but it must not be allowed to rest where it is. A university, capable of granting degrees to London students on similar terms to those on which they are conferred on Scotch and provincial students, must be established in London in the interests of general education, and especially of the large number of medical students in the metropolis."

The Medical Societies.

In the following review of the work of the Medical Societies of Great Britain and Ireland, the endeavour has been made rather to indicate the salient points of some of the more prominent communications than to catalogue them all. Speaking generally, the greatest advance of the year appears to have been in the direction of abdominal surgery, while in medicine the treatment of diphtheria and other maladies by serum extracts has engrossed much of the attention of investigators. The clinical meetings of the various societies continue to be much the best attended, and those papers proved most attractive which dealt with series of cases accurately observed and compared rather than the disquisitions upon single rare instances of disease.

In the department of Medicine we notice first the valuable Lettsomian Lectures by Dr. FREDERICK ROBERTS on the Combinations of Morbid Conditions of the Chest. These were full of practical information and have been widely read. Dr. COLMAN, in a thoughtful paper on the Treatment of Epilepsy, advocated large doses of bromides to control the fits and the use of specially constructed pillows to prevent suffocation at night. Sir BENJAMIN WARD RICHARDSON spoke on the subject of Cycling and Heart Disease from the

Digitized by Google

standpoint of a sixteen years' practical cyclist, and concluded in favour of the exercise in persons of healthy heart, and that even in cases of heart disease cycling was not to be always of necessity excluded. Dr. P. W. LATHAM, in a paper on the Administration of Salicylates in Acute Rheumatism, advocated the use of salicylic acid itself in the form of pills, with calomel purges and milk diet. A case in which an Aortic Aneurysm perforated into the superior vena cava was related by Dr. ALEXANDER BRUCE. The Treatment of Empyema in Children formed the subject of a paper by Dr. CAUTLEY, and he compared incision with resection, to the disadvantage of the latter, especially in children under two years of age. Dr. PASTEUR read a paper on the Association of Respiratory Paralysis with Cardio-pulmonary Symptoms in Diphtheritic Paralysis, based on an analysis of thirty-two cases treated at the North-Eastern Hospital for Children, Hackney. He concluded that the mortality from this affection was higher than had been supposed. Dr. CATON described a case of Acromegaly in a female aged twenty-seven years which was much benefited by the alternate administration of thyroid and pituitary tablets. Dr. FREDERICK TAYLOR read a paper on the Causation of Ægophony, in which he regarded it as discord or dissonance, but his views were ably disputed on musical grounds by Dr. MAGUIRE. Dr. PATRICK MANSON delivered the Hunterian Oration on a Microbe of Malaria. He emphasised the extreme value of microscopic examination of the blood as an aid to the diagnosis of paludism. Professor FRASER opened a discussion on Cardiac Therapeutics with a paper on the remedies employed in cardiac affections and their indications. In the course of it strophanthus was lauded as the most generally applicable of all the specific cardiac agents. Dr. HECTOR MACKENZIE, in a paper on Hysterical Deafness, quoted a case in which it affected both ears and remarked on the paucity of literature on the subject. Dr. H. C. TWEEDY gave details of a case of Symmetrical Gangrene of the Ears which was not due to Raynaud's Disease. Dr. JAMES TAYLOR read a paper on Nervous Symptoms and Morbid Changes in the Spinal Cord in certain cases of Profound Anæmia. The sclerosis present was due to a double cause, to small hæmorrhages and as a resultant of a blood state. The Treatment of Empyema in Children was dealt with in a paper by Dr. COUTTS. He inclined to the opinion that simple incision was preferable in infants. Dr. S. WEST related a case of Serous Pleuritic Effusion of eighteen months' duration for which the chest was tapped thirty-seven times and the side then incised, the result being complete recovery with full expansion of the lung. The routine treatment of Acute Pleural Effusion by Incision was subsequently advocated by Dr. A. WILSON. A case of Sclerema Neonatorum was described by Dr. A. GARROD. Dr. ALEXANDER MORISON read a paper on Syncopal Bradycardia, which he divided into five classes. Dr. WILLIAM HUNTER read a paper on the Use and Abuse of Antipyretics. Dr. WILLIAM RUSSELL read a paper on the Palliative Treatment of Jaundice from Malignant Obstruction, the gall-bladder being opened and drained to relieve cholæmia. Dr. S. WEST described a case of Recovery from Tuberculous Meningitis. The Influence of Cobra Venom on Rabbits was discussed by Professor FRASER. A paper was read by Dr. CHURTON on the Utility of Testing for Indican in the Urine. The subject of Spasmodic Asthma was discussed by Dr. GOODHART. Mr. R. W. LLOYD recorded a case of Strychnia Poisoning in which chloroform was administered for upwards of six hours. A paper was contributed by Dr. J. C. DUNLOP on Oxaluria and the Secretion of Oxalic Acid in the Urine; he found this to be a normal constituent of the urine of all men eating an ordinary mixed diet.

Papers on surgical cases have been more than usually abundant during the year, and in many instances it is satisfactory to note that the writers have supplemented the purely surgical details by reference to the results of bacteriological examination. Mr. ARBUTHNOT LANE described his operation for certain cases of Congenital Dislocation of the Hip-joint by placing the head of the femur in a cavity cut in, and beneath, the anterior inferior spinous process of the ilium. Mr. HUTCHINSON opened a discussion at the Royal Medical and Chirurgical Society on the Affections of the Nervous System occurring in the Early (Secondary) Stages of Syphilis. It was held that in most cases the nervous disease was secondary to disease of the bloodvessels, and that the affections were usually acute and destructive unless prompt treatment was adopted. Dr. JAMES TAYLOR later read a paper dealing with three groups of Syphilitic Diseases of the Brain. Dr. WALLIS ORD and Mr. EDWARD COTTERELL brought forward a case in which Linear Craniectomy was performed for Microcephalus with a beneficial result. Mr. J. L. STRETTON related a case of Castration for Enlarged Prostate, in which after operation the prostate had shrunk to half its original size, and the patient passed urine naturally. The after-history of this patient, together with the necropsy, was detailed later. Mr. MANSELL MOULLIN related two cases in which Orchotomy was performed for Enlarged Prostate. Mr. BRUCE CLARKE read a paper on Thirty Cases of Nephrorrhaphy with their results. In the greater number he had operated because pain was the prominent symptom, and he detailed the after-history of the whole of them. Mr. HERBERT ALLINGHAM gave in a paper the results of operation on a series of cases with Lesions of the Stomach; and Mr. DUNN, Mr. SILCOCK, and Dr. LEES related cases of Laparotomy for Gastric Ulcer. Dr. MCBRIDE discussed some questions with regard to the Diagnosis, Prognosis, and Treatment of Suppuration in the Middle Ear and the Nasal Accessory Cavities. Mr. BALLANCE brought forward a case of Fracture Dislocation of the Spine, in which improvement followed laminectomy. Mr. CHARLES BALL read a paper on the Arrest of Bleeding by Sutures, with special reference to the operations for Varicocele, Nævus, and Varicose Veins of the Leg. Mr. REGINALD HARRISON described a case of Large Pelvic Hydatid successfully treated by Perineal Incision and Drainage. Mr. HOWARD MARSH read a paper on the Clinical Study of some of the more important Forms of Abscess. Mr. GOLDING-BIRD advocated early Erasion in Inflammation of the Sacro-iliac Joint. The Diagnosis of Retroperitoneal Sarcoma was discussed by Mr. C. B. LOCKWOOD. Mr. BERNARD PITTS contributed some practical remarks on the Surgery of the Rectum. Mr. HEUSTON read a paper on Excision of the Rectum in Malignant Disease implicating

Digitized by Google

the Middle Third of the Bowel, advocating a modification of the old perineal operation in such cases. Dr. ST. CLAIR THOMSON and Dr. R. T. HEWLETT contributed a paper on the Micro-organisms found in the Healthy Nose. They found pathogenic organisms only infrequently in the Schneiderian membrane. Mr. W. H. BATTLE described a case of Calculus of the Kidney associated with Simple Growth in the Renal Pelvis. Mr. WALSHAM related an instance of Intra-peritoneal Rupture of the Bladder in which suture was followed by recovery. A specimen illustrating the treatment of Imperforate Anus was shown by Dr. KIDD. Mr. A. G. MILLER read a paper on the Treatment of Fractures near a Joint, in which he advocated massage and movement. Mr. LOCKWOOD contributed a paper on the Operation for the Radical Cure of Hydrocele by Excision of the Sac. Mr. ARBUTHNOT LANE read notes of five cases of Bony Ankylosis of the Temporo-maxillary Articulation in Children. Dr. ADOLPH BRONNER took as the subject of his Presidential Address before the Bradford Medico-Chirurgical Society the Complications and Treatment of Otorrhœa. Mr. MANSELL MOULLIN read a paper on Suprapubic Cystotomy and Prostatectomy in cases of Multiple Calculi. A curious case of Fragilitas Ossium was related by Mr. LANGTON. Dr. DAVIES, in opening a discussion on the Curability of Cancer by Surgical Operation, said that evidence went to prove that cancer was something far other than a mere local disease. Mr. JOSEPH COLLIER related a case of Abscess of the Spleen in a woman aged forty-five years who had never been abroad. In a discussion on Colotomy Mr. WHEELER recommended the anterior or inguinal method, while Mr. CROLY preferred the lumbar operation. Mr. EDMUND OWEN, in a paper on the Operative Treatment of Cleft Palate, argued that this operation should be performed at the earliest available moment. Two cases of Injury to the Roots of the Brachial Plexus were described by Dr. BEEVOR. Mr. BRYANT read a paper on the Diagnosis and Treatment of Early Cancer and Cysts of the Breast, and he emphasised the importance of incision as a preliminary to excision in all doubtful cases. Five successful cases of Nephrectomy for Hydronephrosis were recorded by Mr. ANDERSON. An interesting case of Fracture of the Ethmoid Bone with Basal Meningitis was related by Mr. W. H. BROWN.

In the department of Abdominal Surgery Mr. J. D. MALCOLM read a paper on the Modes of Death from Ovariotomy. He emphasised the importance of making a selection of cases for operation, which was one of the most difficult duties, and perhaps the most important one, of the surgeon in this branch of his art. He showed that septicæmia was the most common danger of abdominal surgery, but that in uncomplicated cases of ovariotomy it was preventable by the use of antiseptics and by care, and that functional and mechanical disturbances of the bowel were special dangers after operation. There were numerous contributions during the year of great interest from the operator's point of view. Mr. MAYO ROBSON read accounts of cases of Tuberculous Disease of the Liver, of Complete Volvulus and Strangulation of the Great Omentum, and of Traumatic Hæmorrhage without External Wound. Mr. FREDERIC EVE described a case of Acute Intestinal Obstruction from Gall-stone; he advocated early laparotomy and forcing the stone if possible through the ileo-cæcal valve. Mr. MAYO ROBSON later dealt with the varieties of Intestinal Obstruction dependent on Gall-stones. Mr. WILLIAMSON showed a case in which he had performed Laparotomy for Partial Rupture of Intestine. The methods to be adopted in cases requiring Resection of Intestine were described by Mr. CAIRD, and Mr. KEETLEY drew conclusions from twenty cases on which he had operated. Dr. TAYLOR read a paper on Retro-peritoneal Rupture of the Duodenum. Mr. HERBERT ALLINGHAM contributed a series of cases of Intestinal Resection. The subject of Perityphlitis was discussed by Mr. SYMONDS, his paper being founded on twenty-three cases which had come under his care for surgical treatment. The cases were, of course, divided into the two groups of relapsing typhlitis operated upon in the quiescent stage and acute suppurating lesions. Of the cases of relapsing typhlitis one was operated upon after a first attack and four after two attacks. In the acute cases he considered the danger was much increased by the removal of the appendix when an abscess existed. Mr. TREVES later gave an additional series of eighteen cases of Relapsing Typhlitis which had been operated upon in the quiescent period, and in discussing the diet advisable to ward off attacks recommended the avoidance of milk. Mr. PRIDGIN TEALE read a paper on the Disruption of Impacted Biliary Calculi; in three cases a gall-stone in the common duct was broken up by the needle. Mr. MALCOLM related in detail all the cases of Liver and Gall-duct Surgery that had come under his care. Mr. ARBUTHNOT LANE read notes of a case of Rupture of the Gall-Bladder and Liver produced by violent straining in a patient suffering from Obstructive Jaundice. Mr. J. HUTCHINSON, jun., described a case of Intestinal Obstruction produced by a Gall-stone the small diameter of which was less than that of the Murphy's button designed for the small intestine. Mr. GILBERT BARLING related a case of Gangrenous Umbilical Hernia in which a successful result followed resection with use of Murphy's button. Mr. JACOBSON contributed a paper on Some Points connected with the Question of Operation in Acute Intestinal Obstruction. Dr. LUCAS BENHAM and Mr. SILCOCK gave details of a case of Acute Intestinal Obstruction due to Volvulus of the Sigmoid Flexure in a female aged fifty-six. A new method of performing Abdominal Hysterectomy was described by Mr. F. B. JESSETT, the peritoneal flaps being everted and drawn down through the vagina. A curious case of Intussusception through a Patent Meckel's Diverticulum was placed on record by Mr. GOLDING-BIRD. Dr. HALE WHITE and Mr. GOLDING-BIRD communicated the particulars of a case of Membranous Colitis treated by Right Colotomy, repeated Irrigation of the Large Intestine, and subsequent Closure of the Wound.

In the branch of Obstetrics and Gynæcology some points in the treatment of Peritonitis were brought forward by Dr. JOHN SHAW. A paper by Dr. J. W. BALLANTYNE gave an account of the references to Antenatal Diseases and Injuries found in the Hippocratic Writings. Dr. MALINS opened a discussion on the Treatment of Post-partum Hæmorrhage, laying considerable stress upon prophylactic treatment and the treatment of those called

Digitized by Google

"flooders." The clinical report of the Rotunda Lying-in Hospital for the year 1892-3 by Dr. SMYLY, Dr. GLENN and Dr. TWEEDY, showed that as a result of the precautions taken against infection there had been a great reduction in the morbidity of the patients during the last few years. They defined "morbidity" as meaning the number of cases in which the temperature even once exceeded 101·4° F. Dr. R. J. PROBYN-WILLIAM and Mr. LENNARD CUTLER gave a paper on Some Observations on the Temperature, Pulse, and Respiration during Labour and the Lying-in. They considered that the low rate of the pulse after delivery, as given in the text-books, was exaggerated. Dr. CLEMENT GODSON delivered the inaugural address at the British Gynæcological Society on the Evolution of Obstetrics and Gynæcology, in which he advocated that those who taught midwifery and gynæcology should be ranked on the surgical side of hospital staffs. Dr. FREELAND BARBOUR contributed a Study of the more recent Frozen Sections in their Bearing on the Mechanism of Labour and the Third Stage. Cases of Tubal Gestation were related by Mr. W. A. STOTT, the rupture occurring in the middle portion of the left Fallopian tube, and by Mr. BLAND SUTTON, showing the advantages following immediate laparotomy. Dr. MORE MADDEN gave full attention to the subject of leucorrhœa. Mr. BOWREMAN JESSETT showed a specimen consisting of the entire Uterus, which had been the seat of Epithelioma of the Cervix. The growth was first scraped away as much as possible, and then the cavity packed with chloride of zinc paste. "The Dangers of Morphia in Gynæcological Practice" was the title of a paper from the pen of Dr. MACNAUGHTON JONES. Dr. LEONARD REMFRY read a paper on Ovariotomy in Women over the age of eighty years. Ten cases were referred to, all of which recovered. A paper was contributed by Dr. GLENN on the Methods of using Normal Saline Solution in Severe Hæmorrhage and he recorded the results he had obtained in seven cases. Dr. C. HUBERT ROBERTS read a paper on the Pathology of "White Leg" after Childbirth. A paper on the Influence of the Removal of the Ovaries on Metabolism by Professor E. CURATULO and Dr. LUIGI FARRULI of Rome tended to elucidate the cause of the benefit received in osteomalacia by removal of the ovaries. Dr. H. MITCHIE read a paper on Pregnancy complicated by Suppuration within the Pelvis, illustrated by six cases divided into three groups. Dr. CHAMPNEYS and Mr. BOWLBY contributed a paper on the Development of Mammary Functions by the Skin of Lying-in Women, and they found that the axillary lumps consisted of modified skin glands. A paper on Chorea Gravidarum was contributed by Dr. R. C. BUIST, and contained a careful digest of 255 cases where this complication of pregnancy existed. Dr. FANCOURT BARNES read a paper on Some Difficulties in the Use of the Curette, the two principal conditions calling for the use of the curette being chronic endometritis and retained products of conception. The question of the Advisability of registering Midwives in Scotland was discussed by Dr. D. BERRY HART. Dr. W. S. A. GRIFFITH and Dr. T. G. STEVENS contributed a paper entitled, "Notes on the Variation in Height of the Fundus Uteri above the Symphysis Pubis during the Puerperium, the Conditions which influence this, and the Practical Conclusions which may be drawn from such Observations." Certain Micro-organisms of Obstetrical and Gynæcological Interest were studied by Dr. G. D. ROBINSON. Dr. HERMAN discussed the subject of Vaginismus and Allied Affections.

In the department of Pathology it may be said that bacteriology and pathological chemistry have been more in evidence than mere exhibitions of morbid anatomy. Dr. WASHBOURN read a paper on the Pneumococcus, with especial reference to Immunity; and he was followed by Dr. A. E. WRIGHT with a paper on the Bacteriology and Pathological Chemistry of Pneumonia. The Pathology of Diphtheria was also dealt with from the bacteriological side by Mr. BERTRAM HUNT and others, and Mr. W. ROBERTSON described the Method of producing Immunisation of Horses. The question of the Classification of Epithelial Morbid Growths on Morphological Attributes *per se* was discussed by Dr. HERBERT SNOW and others. Dr. VOELCKER described a case of Carcinoma of the Ureter involving its lower two inches and not projecting into the bladder. Dr. FRANCIS HAWKINS exhibited a specimen showing Congenital Obliteration of the Ductus Communis Choledochus. The paper read by Dr. FELIX SEMON on the probable Pathological Identity of the various forms of Acute Septic Inflammation of the Throat excited a discussion which exhibited the difficulty of establishing a satisfactory criterion of identity in its pathological sense. Dr. ORD and Mr. SHATTOCK made a communication on the Microscopic Structure of Calculi of Oxalate of Lime. Dr. PLOWRIGHT read a paper on the Spontaneous Fracture of Uric Acid Calculi. Dr. J. R. BRADFORD gave an account of the Results following the Removal of Portions of the Kidney. The Pathology of Graves's Disease was elucidated by observation and experiment by Mr. W. EDMUNDS. Dr. VAUGHAN HARLEY read a paper on Absorption and Metabolism in Obstruction to the Pancreatic Duct. Mr. D'ARCY POWER showed a case of Primary Sarcoma of the Vagina in a young Child. Mr. JACKSON CLARKE discussed the subject of Tertiary Syphilitic Lesions in Lymphatic Glands. Sir DYCE DUCKWORTH related a case of Sudden Death due to Cardiac Syphiloma. Dr. T. HARRIS read a paper on the Clinical Value of Inoculation Experiments in Guinea-pigs in the Diagnosis of Tuberculous Phthisis. The Pathology of Certain Forms of Vesical Tumour was illustrated by Mr. J. H. TARGETT. Dr. ARCHIBALD GARROD and Mr. HOPKINS contributed notes on the Occurrence of Large Quantities of Hæmatoporphyrin in the Urine of Patients taking Sulphonal. The Relation of Biliary Calculi to Malignant Disease of the Liver was discussed by Mr. C. BEADLES. Mr. BATTLE read a paper on Acute Inflammation of Bone as it is met with in children over five years of age, dividing these cases into three classes. Mr. LEOPOLD HUDSON instituted a comparison between the Lesions found in the Large Intestine of Pigs in Swine Fever and those seen in Human Ulcerative Colitis. Dr. J. W. BALLANTYNE commenced a series of papers on Teratogenesis, or an Enquiry into the causes of Monstrosities. One of the most interesting discussions of the year was that instituted by Mr. HUTCHINSON on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues, and in the course of it many new facts were brought forward. Mr. E. A. PETERS produced the result of his study of the

Digitized by Google

Varieties of Diphtheria Bacilli, and Mr. J. EYRE did the same with Neisser's Xerosis Bacillus. Mr. ROGER WILLIAMS, in discussing the Pathogenesis of Cancer, came to the conclusion that in the great majority of cases the outbreak of the disease was spontaneous, and could not be attributed to the immediate action of any appreciable extrinsic cause. Dr. DRESCHFELD, in a communication on the Etiology of Malignant Endocarditis, enumerated the various micro-organisms which had been found to act as causative agents. Dr. MCWEENEY described two cases of Tumour of the Kidney composed of Suprarenal Tissue.

Turning to Ophthalmology, we note that a paper upon 100 operations for Senile Cataract was read by Mr. J. B. STORY, who dwelt upon the importance of thorough asepsis as the principal factor in determining the result of a cataract extraction. Mr. W. H. JESSOP described two cases of Diphtheritic Conjunctivitis treated by Klein's Antitoxin. Mr. WRAY read a paper on Removal of the Lens in High Myopia with a view chiefly to arrest morbid changes in the retina and choroid, but also to enable patients with the highest grades of myopia to work at reading distance if unable to do so. Mr. WRAY later read a paper on the Treatment of Detached Retina. Mr. MACKAY contributed a paper on Eyesight and the Public Services, which pointed out the unsatisfactory manner of conducting the visual examinations at present adopted. Mr. W. A. BRAILEY described a peculiar form of Iritis not usually recognised. Dr. MULES brought forward a new operation for Ptosis, the principle of the operation being to substitute the frontalis muscle for the levator palpebræ. Mr. TREACHER COLLINS read a paper on Blood-staining of the Cornea, the pigment being precipitated hæmatoidin. Mr. J. B. LAWFORD described some cases of Ophthalmia Nodosa due to the penetration into the eye of the hairs of certain varieties of caterpillars. Mr. SIMEON SNELL collected notes of nine cases of Chancre of the Conjunctiva, and remarked that though these cases were not uncommon, yet very few had been reported.

Some good papers were contributed on the Administration of Anæsthetics. Mr. BERNARD STEDMAN related the extremely satisfactory results he had obtained by Rectal Etherisation as a method of induction and maintenance of general anæsthesia. Dr. FREDERIC HEWITT and Mr. MARMADUKE SHIELD brought forward a paper on Posture in its relation to Surgical Operations under Anæsthetics. The posture of the head in its relation to that of the trunk was discussed, the postures of surgery were individually considered, the posture of the patient after operation was described, and the influence of the force of gravity upon the circulation and respiration was dealt with.

In the Department of Public Health Dr. T. M. LEGGE contributed a paper on some Points of Difference between English and Continental Methods of Municipal Sanitary Administration. The other countries visited for purposes of investigation and comparison were Sweden and Norway, Denmark, Belgium, France, and Germany. An interesting historical communication on Epidemic Diseases in the Royal Navy came from the pen of Fleet-Surgeon THEODORE PRESTON. A debate took place at the Society of Medical Officers of Health on the Connexion between Female Labour in Factories and the High Infant Mortality in certain Manufacturing Towns. Mr. H. C. JONES read a paper on the Legal Definition of Sewers and Drains, and it was shown that the law required amendment. A paper on the Relations between the Conditions of the Soil and the Prevalence of Epidemic and Endemic Diseases was read by Brigade-Surgeon-Lieutenant-Colonel LANE NOTTER. Dr. NEWSHOLME advocated a National System of Registration of Sickness. Dr. SIDNEY DAVIES read a report on an Outbreak of Enteric Fever distinctly traceable to a particular Milk-supply, though the actual cause could not be discovered.

Amongst the papers on Miscellaneous Subjects was one by Dr. FELIX SEMON on a novel form of Malingering—namely, Chronic Self-inflicted Ulceration of the Throat—the point of diagnostic value being the abrupt cessation of the lesion above and below, at parts inaccessible to the patient. Dr. INGLIS PARSONS read a paper on the Disintegration of Organic Tissues by High Tension Currents, the experiments being undertaken to ascertain the capabilities of electricity as a destructive agent in the treatment of malignant disease. Mr. G. STOKER showed how hair could be made to grow by the local imprisonment of oxygen gas over the area to be cultivated. Dr. IMLACH read a paper on Modern Miracles of Healing. Mr. F. R. HUMPHREYS read a paper on the Necessity for a Central Organisation in the Medical Profession. Dr. E. SYMES THOMPSON read a paper on the Climate of Egypt, comparing it with that of the Alps, the Canaries, and the Cape. A thoughtful paper by Dr. T. SEYMOUR TUKE on Lunacy and General Practice referred to some of the duties, difficulties, and responsibilities of the private practitioner with regard to mental cases.

In concluding this notice of the work of the Medical Societies for the year we are happy to record progress all along the line. Especially successful have been the discussions which have taken place on selected subjects, though here it would be a great improvement if the learned monographs compiled by the introducers of the subjects to be debated upon were printed and "taken as read" by the societies, as more time would thus be allowed for spontaneous interchange of opinion.

Special Sanitary and Analytical Commissions.

The activity of the Analytical Department of THE LANCET has been fully maintained. No less than 150 samples coming under the heading of Food and Drugs were examined during the year. The total number of analytical results published was 500, of which 265 were included under the heading of Analytical Records, while 235 were made in connexion with special inquiries. The number of new inventions examined in the laboratory was twelve.

Of the special inquiries the work of our Commissioners on the incandescent gas light from a hygienic point of view was, perhaps, the most exhaustive. The whole of the work, except the determination of illumination values, was done in THE LANCET Laboratory. The inquiry was undertaken in the interests of the public in consequence of certain statements appearing in print and elsewhere that this burner gave off (*inter alia*) carbon monoxide. The results were such as to free it entirely from any reproach on this head, and, on the contrary, showed that this system of lighting possessed distinct economic and

Digitized by Google

hygienic advantages, while its superior lighting powers were quite evident. The report, which appeared in the first issue of THE LANCET of the present year (Jan. 5th), contains an interesting account of the history of the progress and development of incandescent gas lighting, and a description of the processes of manufacture of the incandescing filaments.

Munich beer was the next subject of analytical inquiry. Analyses of the materials used in its manufacture, the water, yeast, malt, and the finished product itself, were made. It was shown that, in spite of the fact that Munich beer contains a greater proportion of nutritious malt extractives than the strongest beer, yet the proportion of alcohol is only one-half as much. Moreover, the quantity of hops used is considerably less. These were facts which it was considered accounted sufficiently for the less stupefying effects of Munich beer.

In the spring our Commissioners were invited to inspect the system of ventilation combined with a method of treating infected air, which it was proposed to introduce into the New General Hospital at Birmingham. The system, which was fully described in THE LANCET of Feb. 16th, consisted in propelling air after being warmed and screened through moist fibre screens, and, in the event of infectious disease, in placing similar screens—moist, if desired—with an antiseptic at the points of exit. Our Commissioners expressed a favourable view of the propulsion system, and in their opinion the addition of an arrangement for disinfecting the outgoing air was one of the best suggestions that had been made in connexion with avoiding the probability of infection being spread by infectious diseases hospitals. Favourable results of bacteriological analyses of the outgoing air in a series of experiments were quoted in support of this view.

The production of both an enzyme and ferment from a certain class of fungi was the next subject investigated. The report appeared in THE LANCET of May 25th. Interesting features in this process were the rapid production of diastase, which was shown to possess very high digestive powers on starch, and the growth of a pure and active yeast, which quickly excited alcoholic fermentation.

Recent important improvements in the preparation of cod-liver oil and castor oil were the subject of our Commissioners' attention in an article in THE LANCET of June 8th. The improvements were directed in each case to palatability, digestibility, and increased efficiency, each of which had been secured—in the former case by carefully excluding decomposed albumins by extracting the oil from the livers by means of steam and the prevention of the formation of hydroxy-acids, and in the latter by extracting the oil from the seeds in the cold and carefully excluding the drawn product from the action of the air.

The department is at present engaged upon some important inquiries which have already occupied a good deal of time and attention, but the results are not yet complete. It is hoped, however, that they will be ready for publication in the first number of THE LANCET in 1896.

The Benevolent Agencies of the Profession.

Christmas week is a time for remembering the claims of these agencies. It is sad to have to report that they are still inadequate to meet the demand for their help. The letter of Sir WILLIAM BROADBENT as treasurer of the British Medical Benevolent Fund in THE LANCET of Nov. 9th is eloquent in the simplicity of its pitifulness. During the year 174 cases had come before the committee and 119 grants had been made amounting to £1083, giving an average of only £9 instead of £12 or £18, and latterly even that had to be reduced to £5 or £6. At the last preceding meeting (in October) twenty cases had to be considered, besides those postponed from September, and there was only the sum of £34 to meet the claims to be made for the rest of the year. Next week we shall publish the seventh annual report of THE LANCET Relief Fund, which, as our readers are aware, is intended to give prompt, and, it is hoped, permanent, help to those who have fallen into pressing need of immediate pecuniary assistance. The Royal Medical Benevolent College has happily been able to make an advance in its capacity for helping the profession, both in the way of assisting the education of boys the sons of medical men, and of increasing grants made to non-resident pensioners. On Monday, July 8th, His Royal Highness the Prince of WALES laid the foundation of the new lower school buildings, in which 100 of the younger boys, separated from the main buildings, will be accommodated. No less than fifty boys, sons of medical men, are educated on the foundation free of all cost, and many more receive assistance. This is a very gratifying report. The Widows' and Orphans' Fund continues its admirable work in relieving the widows and fatherless children of those members of the profession within the metropolitan area who had the means and the forethought to provide for their families. The pity here is that so easy and benevolent a form of life insurance is not more appreciated and that many practitioners who could by a little self-denial provide against "the rainy day" do not do so. But the lot of the widow and the fatherless is not the less sad because of want of thought or want of means on the part of the deceased breadwinner. The Christmas help of medical men cannot be better bestowed than in assisting such excellent funds. Their good work is undoubted and deserves constant encouragement.

Honours to Medical Men.

The time when the services which medical men render to the community shall be fully recognised by a grateful State is not yet; but if the list of Medical Honours during the past year is not so large as might reasonably have been expected it contains names of which not only the profession but all English-speaking peoples, and, in fact, the whole world, may be proud. Among the list of names which HER MAJESTY selected for the bestowal of New Year Honours were those of Dr. RUSSELL REYNOLDS, the President of the Royal College of Physicians of London, and Mr. ERICHSEN, a past-President of the Royal College of Surgeons of England. Both these gentlemen received Baronetcies, and the honour done to Sir J. RUSSELL REYNOLDS and Sir J. ERIC ERICHSEN was hailed with keen satisfaction by the whole of their medical brethren. Only three gentlemen whose names appear on the Register of the General Medical Council were selected to receive honours on the occasion of HER MAJESTY'S seventy-sixth birthday—Dr. JOSEPH EWART of Brighton, Director-General JAMES NICHOLAS DICK, C.B.,

Digitized by Google

and Dr. SALVATORE PISANI. Sir JOSEPH EWART received a Knighthood, Sir JAMES NICHOLAS DICK a Knight Commandership of the Bath, and Dr. SALVATORE PISANI was made Companion of the Order of St. Michael and St. George. Sir WILLIAM HALES HINGSTON and Sir JOHN CHRISTIAN SCHULTZ received the honour of Knighthood and Knight Commandership of the Order of St. Michael and St. George respectively on the same occasion. The promulgation of the long-delayed rewards and honours for Chitral disclosed the fact that Surgeon-Major GEORGE SCOTT ROBERTSON, C.S.I., had been gazetted as a Knight Commander of the most exalted Order of the Star of India, and that Surgeon-Captain HARRY FREDERICK WHITCHURCH had received that coveted decoration, the Victoria Cross. It is unnecessary to recapitulate here the story of his bravery, for it is known, we believe, by every member of a profession which must feel a thrill of justifiable pride whenever the name of Surgeon-Captain WHITCHURCH, V.C., is mentioned. The Waziristan honours list included the names of Surgeon-Colonel LIONEL DIXON SPENCER, who was made a Companion of the Most Honourable Order of the Bath, and Brigade-Surgeon-Lieutenant-Colonel GEORGE MCBRIDE DAVIS, who was made a Companion of the Distinguished Service Order. Sir CHRISTOPHER NIXON, Physician in Ordinary to the Lord-Lieutenant of Ireland, and Sir W. THORNLEY STOKER, President of the Royal College of Surgeons in Ireland, on the retirement of Lord HOUGHTON from the post of Lord-Lieutenant of Ireland, received their Knighthoods. Sir H. D. LITTLEJOHN of Edinburgh also received his Knighthood during the past year. The latest honour announced is the bestowal of a Knight Commandership of the Order of St. Michael and St. George upon Dr. L. A. A. DE VERTEUIL, President of the Trinidad and Tobago Branch of the British Medical Association.

The Metropolitan Hospital Sunday Fund.

The present year will be a memorable one in the annals of the Metropolitan Hospital Sunday Fund, for the sum collected on behalf of the sick poor of the metropolis has far exceeded the amount obtained in any previous year. Twenty-three years ago, when the Fund was started, the total receipts amounted to £27,700 8*s*. 1*d*., and the collections and donations steadily rose till last year, when they reached a total of £43,679 11*s*. 8*d*. This year they have reached the unprecedented total of £60,361 4*s*. 2*d*., which, after allowing for liabilities and the usual expenses, a little over 2 per cent. of the whole, was distributed among 121 hospitals and 53 dispensaries, 5 per cent. being set apart for the purchase of surgical appliances. The large increase is due, in a great measure, to special donations and legacies. Three donations each of £1000 were received from Lord IVEAGH, Sir SAVILE CROSSLEY, and Mr. J. B. ROBINSON. Mr. B. I. BARNATO, Mr. DANIEL MARKS, and their friends contributed £10,000, and the members of the Stock Exchange, through Messrs. BURDETT and HARRIS, and Messrs. PIM, VAUGHAN and Co., gave £3400. The Rev. CANON FLEMING, Vicar of St. Michael's, Chester-square, headed the list of congregational contributions with £1180 10*s*.; the Rev. C. J. RIDGEWAY, Vicar of Christ Church, Lancaster Gate, followed with £1170 18*s*. 11*d*.; and the Rev. Prebendary EARDLEY-WILMOT, Vicar of St. Jude's, South Kensington, came next with £804 5*s*. As we have said, the unprecedented sum reached this year is greatly owing to special gifts, but it is encouraging to note that year by year the sums received from the various churches show a steady rise. Another noticeable point is the confidence placed in the distribution committee and in their methods of administration. This confidence in the distribution committee assures us that the success which has attended the strenuous efforts of the friends of the Fund during the past year, under the presidency of Sir JOSEPH RENALS, will be maintained under the presidency of his successor in the Mayoral chair, Sir WALTER WILKIN.

Obituary.

We have always to count upon deaths in our ranks which seem premature, those of men cut off in the very prime and promise of their lives. This year some very sad instances had to be recorded in our pages, such as that of ALFRED W. STURDEE, of H.M.S. *Hood*, who was drowned while bathing at Gozo. In one number of THE LANCET—that of March 30th—we had to report the death of three young practitioners from various causes, and throughout the year such incidents of death have been too frequent. Some died as veritable martyrs to heroic ideas of self-sacrifice. SYDNEY WEBB, M.D. Edin., had had an appointment on the Congo as missionary without salary, and had worked for two years, sometimes seeing 120 cases a day. His time for rest and holiday had come, but on the voyage home he died. Similar in its devotion and sense of duty was the fate of GEORGE STEELE, M.B. Glasg., who died from fever after most effective missionary work in Nyassaland, Central Africa. Not less heroic and noble was the death of JOHN THOMAS REESE, who persisted in crossing a mountain in a thunderstorm to see a poor patient, and who was struck dead by lightning. Three thousand people attended his funeral. Some striking instances of the old tendency of medicine to run in families came to light—that of JOHN ABERNETHY WICKS of Emsworth, Hants, whose family had practised thereabouts for 150 years, and that of JOHN WHITAKER HULKE, whose family for 200 years had practised medicine. Some fine instances of long life and service will be found in our biographies. LOUIS FLORENTIN CALMEIL, M.D., who first discerned the nature of general paralysis, died at the ripe age of ninety-seven after "a life of devotion to his poor patients and to researches into their diseases," which gained him the Cross of the Legion of Honour. EVAN PIERCE, M.D. St. And., of Denbigh, died at eighty-seven, having during his own and other generations supported a hospital of fifteen beds, and given his town public pleasure grounds and a public hall. EDMUND CHARLES JOHNSON, F.R.C.S. Eng., J.P., D.L., in early life abandoned very good prospects to advance the cause and comforts of the blind, having contracted the ardour in this cause by attending Lord CRANBORNE, brother of our distinguished Premier, who suffered the misfortune of blindness. THOMAS GROOM of Whitchurch died at eighty-six, having spent over sixty years in the relief of suffering, with occasional recreation, for he used to tell of one forenoon in

Digitized by Google

the "forties," before the days of breechloaders, when he brought down thirty brace of partridges in the neighbourhood of Whitchurch.

If the death of members of the profession in the first rank of authority and eminence is a disaster, then few years have been more disastrous than 1895, as a few names from our obituary will show: JOHN WHITAKER HULKE, F.R.S. and President (at his death) of the Royal College of Surgeons of England; Sir WILLIAM SCOVELL SAVORY, Bart., F.R.S.; DANIEL HACK TUKE, M.D. Heidelberg, F.R.C.P. Lond.; LOUIS FLORENTIN CALMEIL, M.D.; CARL THIERSCH, of Leipzig; CARL LUDWIG, of Leipzig; ARTHUR EDWARD DURHAM, F.R.C.S. Eng.; Sir GEORGE BUCHANAN, M.D. Lond., F.R.S.; CARL VOGT; Sir GEORGE HORNIDGE PORTER, M.D. T.C.D., F.R.C.S. Irel., LL.D. Glasg.; HANS WILLIAM MEYER, M.D., of Copenhagen; the Right Hon. THOMAS HENRY HUXLEY, P.C., F.R.C.S. Eng., F.R.S.; Sir JOHN TOMES, F.R.C.S. Eng., F.R.S.; STEPHEN JENNINGS GOODFELLOW, M.D., F.R.C.P. Lond.; JOHN SYER BRISTOWE, M.D. Lond., F.R.C.P., F.R.S.; LOUIS PASTEUR (for we must claim him), who, though without technical qualification, opened new regions of "healing" and enlarged almost beyond precedent the powers and possibilities of medicine; Sir THOMAS LONGMORE, C.B., F.R.C.S. Eng.; Sir THOMAS CRAWFORD, K.C.B., LL.D.; THOMAS KEITH, F.R.C.S. Edin.; and ROBERT JAMIESON, M.D., L.R.C.S. Edin. All we can say when we think with regret of the vacancy created in science and in medicine by the loss of such men is that if they have accomplished their decease, they had likewise in a high degree fulfilled their mission and their fame, and earned

> "The crown that virtue gives,
> After this mortal change, to her true servants
> Amongst the enthroned gods on sancted seats."

Annotations.

"Ne quid nimis."

A MEDICAL OFFICER DEFENDED BY GUARDIANS FROM UNJUST BLAME BY A JURY.

WHEN will coroners as a matter of bare justice refuse to allow juries to criticise, if not to censure, the conduct of public officers, without giving the said officers the opportunity of defending themselves? The last case in point, at Wakefield, is one which should teach them to always observe this obvious rule. A pauper widow aged seventy years, in receipt of 2*s.* 6*d.* a week from the guardians, procured last year an order for medical relief, and was attended regularly up to last September by Mr. Clayton. He always found her drunk, and on the last occasion near the pillow was a breakfast-cup nearly half full of whiskey. The neighbours said it was perfectly useless doing anything for her, as she was always cursing and swearing and drunk. There was nothing else the matter with her, and he left instructions that if anything else occurred he was to be sent for. He heard no more till December, when a man came for a death certificate, saying that the widow had died suddenly. An inquest was held. No proper notice was given to Mr. Clayton, and he was not present. But the jury spoke as if Mr. Clayton had neglected the patient, and asked the coroner to aquaint the guardians. The guardians went fully into the case and entirely acquitted their medical officer, and properly so. The fact is that the law is at fault in such cases as this in not permitting the authorities to place patients under conditions in which alcohol can be withheld from them. This is one lesson of the case. The other is to coroners not to allow juries to censure without having the facts before them and the persons blamed.

THE RECENSION OF HIPPOCRATES.

THE year must not close without some reference to the light it has thrown on the language and thought of the father of medicine. Under the title of the "Hippocratic Revival"[1] we commented on the contributions just made by Germany and France to the interpretation of Hippocrates, the chief of which is Dr. R. Fuchs's masterly rendering of the "Sämmtliche Werke," now approaching completion. Yet more important, however, is the reconstitution of the text by Hugo Kühlewein, of which the first volume is now before us. It forms the latest addition to the "Bibliotheca Scriptorum Graecorum et Romanorum," published by Teubner of Leipsic, and is a favourable specimen of the beautiful typography, careful editing, and convenient size for which that collection has long been famous. Hitherto, with the exception of Reinhold's two octavos (Athens, 1865, 1866), editions of Hippocrates were too voluminous, like Littre's, or too bulky, like Ermerins', for comfortable use. Such an edition as could really be called "handy" was not to be obtained. Now we have just what was desiderated, along with an *apparatus criticus* that puts the reader in possession of the actual words of the original, as nearly as these can be ascertained by a collation of the best manuscripts. We shall take another opportunity of indicating in detail the superiority of the present to all previous texts; meanwhile we may refer to the three chapters of the Prolegomena as setting forth the broad features in which the present edition is an improvement on its predecessors. The first two are from the pen of that fine medical scholar, Herr I. Ilberg, and treat "De Codicibus Manu Scriptis" and "De Memoria Secundaria"; the third—a very important dissertation—"De Dialecto Hippocratico," is by the responsible editor, Hugo Kühlewein. The motto of the edition is the characteristically Hippocratic rule laid down in the "Epidemics" (I. 5), ὠφελεῖν ἢ μὴ βλάπτειν (to be useful or at least not to injure), and, so far as we have yet been able to judge, Herr Kühlewein may be congratulated on his loyalty to it, not only in the letter, but in the spirit.

SANITATION IN GLAMORGANSHIRE.

DR. W. WILLIAMS, medical officer of health for Glamorganshire, in his report to the County Council for the quarter ended Sept. 28th, gives interesting particulars of much active sanitary work. Scarlet fever and enteric fever have been the prevailing diseases notified in his district, no fewer than 662 of the former and 218 of the latter, as well as 83 cases of diphtheria and 14 of puerperal fever having come under observation; only one case of small-pox was observed. Of the 83 cases of diphtheria 45 occurred in the newly built village of Bedlinog, situated on the uplands in the north-east corner of the county. The inhabitants are principally colliers and their families; there are 297 occupied houses, and the population probably amounts to 1500 persons. The water-supply is good and no illness could be discovered among those who supplied milk to the village. Mr. Dyke of Merthyr, who investigated the circumstances, attributes the origin of the diphtheria to some unhealthy and decayed wooden dwellings where the closets were very foul, and also to the careless manner of emptying cesspit contents in pits in the gardens surrounded by occupied houses. There was

[1] THE LANCET, March 30th, 1895.

Digitized by Google

a considerable outbreak of enteric fever at Pontardawe, where 42 cases, with 8 deaths, occurred between Sept. 27th and Nov. 27th. Several hypotheses have been put forward to explain this epidemic, one of them being that the first person attacked—a tramp from Tredegar—had defæcated in the neighbour hood of the tank from which the public water-supply was derived.

THE FORTHCOMING FRENCH CONGRESS OF SURGERY.

THE Administrative Council of the French Association of Surgery has submitted the following subjects to be laid before the Congress of Surgery which will be held in Paris in October, 1896: 1. Surgical Treatment of Talipes; introduced by M. Forgue, Montpellier. 2. Treatment of Prolapsus of the Genital Organs; introduced by M. Bouilly, Paris. These subjects will be submitted to the general assembly and to every member of the Congress individually.

THE Alvarenga Prize of the College of Physicians of Philadelphia has this year been awarded to Dr. Guy Hensdale for an essay on Syringomyelia. The prize is worth 180 dollars, and the next award will be made on July 14th, 1896, for the best essay on any subject in medicine.

THE deaths are announced of Mr. James Rouse, F.R.C.S., consulting and late senior surgeon to St. George's Hospital, and Mr. John Chippendale, F.R.C.S., a venerable and well-known member of the profession. We hope to give later a somewhat extended obituary of these gentlemen.

DR. DAVID NICOLSON, the Medical Superintendent at Broadmoor Asylum, and President of the Medico-Psychological Association, has been appointed a Lord Chancellor's Visitor in Lunacy in the place of Dr. Lockhart Robertson, who has resigned.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE annual general meeting of constituents of the Metropolitan Hospital Sunday Fund was held at the Mansion House on Wednesday, Dec. 18th, when the Right Honourable Sir WALTER WILKIN, Lord Mayor, President and Treasurer of the Fund, occupied the chair. Among those present were the Greek Archimandrite, Archdeacon Sinclair, the Chief Rabbi, Sir George Bruce, the Rev. Dr. Rigg, the Rev. Dr. Kennedy, the Rev. Dr. Jenkins, Mr. Richard B. Martin, M.P., Dr. J. G. Glover, Dr. Hare, and Mr. J. A. Bloxam.

At the commencement of the proceedings Mr. CUSTANCE, the secretary, announced the receipt of a legacy of £500, free of duty, from the late Mr. John Smith.

The LORD MAYOR having expressed the interest he and all citizens felt in the success of the Fund, which he hoped in the coming year would be productive of still larger sums than in the past,

Archdeacon SINCLAIR moved the adoption of the council's report. The Fund's twenty-third year, he said, had become memorable by the large increase in the funds raised from various sources, bringing in the unprecedented total of £60,361. This was owing very considerably to a great increase in legacies and special donations, including £3000 from the Stock Exchange by Messrs. Pym, Vaughan, and Co. and Messrs. Burdett and Harris, £10,000 from Mr. Barnato and friends, and £1000 each from Lord Iveagh, Mr. J. B. Robinson, and Sir Savile Crossley. Apart from these, it was gratifying to notice that the amount collected in the places of worship had been the largest on record—£38,370—each congregation showing a steady rise. All that was largely due to the efforts and advocacy of the medical journals, particularly THE LANCET and the *Hospital*, who published interesting reports in connexion with the needs of hospitals. If ministers' sermons were dull and ineffective after reading these reports it was certainly their own fault. He himself made a large use every year of the facts given in these journals, which were far more telling than the most verdant rhetoric of their own. He would like to remind the clergy that at the time of the year when the hospital collection was made a very large number of people were out of London, and he advocated the use of a printed form to be sent round to such persons to remind them that although they were not present at church, it would be fitting that they should send in their subscriptions. The numbers of people who attended church on Sunday formed a very small part of the population, and even those who did not attend church might be reached in this way.

The Rev. Dr. RIGG seconded the motion, and said it was a difficult matter to arouse and move the whole of London, the conditions of life being different from those prevailing in large cities such as Birmingham and Liverpool, where the collections on Hospital Sunday showed a better comparison with the numbers and wealth of the population. Still, the success of this year showed what could be done by sustained endeavour. The journals to which the Archdeacon of London had referred had rendered good service, but all must use their endeavours to bring the enormous forces which there are in London to a focus. The motion was carried.

Mr. R. B. MARTIN, M.P., moved that the laws of the constitution which had been in force during the past year should be continued. He said he could remember the history of the Fund from its beginning. He referred to the interest taken in the Fund by Sir Sidney Waterlow at its commencement, who was then Lord Mayor, and the great interest taken in, and impetus given to, the Fund by the late Dr. James Wakley of THE LANCET. The laws of the constitution had worked well for twenty-three years, and he did not believe that any hospital, from the greatest and most important to the smallest and least important, well and carefully managed could fail to receive a grant. He hoped the clergy, taking the course adopted by Dean Forrest, Canon Fleming, and others, would begin collection for the Fund some time before the actual day, and he especially begged that the collections made on Hospital Sunday should be entirely devoted to the Fund and not divided between it and other charities. Referring to the economical way in which the Fund was administered, he said that last year the working expenses sank to 2·69 per cent. of the amount collected, and they might say that practically the whole amount collected was distributed.

The Rev. MAIN S. A. WALROND seconded the resolution, which was carried.

Sir GEORGE BRUCE moved, and the Rev. Dr. KENNEDY seconded, "That the council for the year 1895 be re-elected for the year 1896, with the Rev. Canon Graham, D.D.; the Rev. David Anderson, M.A.; the Rev. M. R. Neligan, M.A.; the Rev. H. Russell Wakefield, M.A.; the Right Hon. the Earl of Stamford; Sir Joseph Renals, Bart.; Mr. Alderman G. Faudel Phillips, and John Astley Bloxam, Esq., F.R.C.S., &c., to fill vacancies." This was agreed to unanimously.

On the motion of the Rev. W. H. BARLOW it was agreed "That June 14th be fixed for Hospital Sunday of 1896, and that the cordial coöperation of all ministers of religion within the metropolitan area be again invited in the usual way."

A vote of thanks to the Lord Mayor, moved and seconded by the Rev. Dr. KITTO and Mr. BLOXAM respectively, terminated the proceedings.

THE ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this society was held on Wednesday, the 18th inst., at the Institution of Civil Engineers, Great George-street, Westminster, Mr. R. Inwards, F.R.A.S., President, in the chair. Mr. R. H. Scott, F.R.S., read a paper on Some of the Differences between Fogs, as related to the Weather Systems which accompany them. In this it was shown that there are at least two distinct classes of phenomena described under the generic name of "fog." In the case of anticyclonic fogs no rainfall takes place, the temperature is low in the morning, and there is a considerable rise of temperature during the day, while in the case of cyclonic fogs rainfall does take place, and the temperature is high in the morning, frequently approaching or even equalling the maximum for the day.

THE CENTENARY
OF
THOMAS WAKLEY.

AN INTRODUCTION TO A BIOGRAPHY OF THE FOUNDER OF "THE LANCET."

THE year which is now closing is the centenary of the birth of the founder of THE LANCET, and, after consideration, we have decided that it is not only a natural inclination, but a clear and unmistakable duty that is prompting the writing of a biography of the late Thomas Wakley. The causes for hesitation are obvious. Firstly, as the father of one and the grandfather of the other of the present editors he may be held to occupy a position in our eyes necessarily removing him from criticism. So that any biography appearing in these pages would, it might be believed, have to be received with particular caution by our readers, the personality reviewed being presented rather as seen with the blurred glasses of family affection than with the candid and independent gaze of the disinterested chronicler. Secondly, the life of Thomas Wakley, the medical reformer, is so intimately bound up with the fortunes of this paper that to tell it in detail is to tell in detail of the origin and progress of THE LANCET, a proceeding which might savour somewhat of editorial egotism. Thirdly, so many years have now passed since his death that an account of his life might be reasonably expected to have lost its chances of a strong hold upon the public, medical or lay.

As against these, and as our reasons for holding that to write this life is our public duty to the profession every whit as much as it is our pleasure, the following may be advanced. Firstly, Thomas Wakley lived so openly before the world, the things that he said and the things that he did were so entirely the public property of his day, that it is impossible for us to place incorrect facts before our readers without being immediately detected, and it is with facts that we shall mainly deal. With regard to the meaning of those facts and the proper deductions to be drawn from them, the lapse of time makes it difficult for us or our readers to go wrong. The lapse of time is all-important. It is impossible correctly to interpret the work of a reformer from day to day, and from hour to hour. When a man lives a life of battle against wrongs and abuses, it is, and must ever be, his fate to be compelled to wait for years without recognition of the value of his work—if value there be—by the persons whose good opinion is alone worth having. The irresponsible and unbalanced agitator, the crank, and the self-advertiser all bear the unfurled banner of the reformer, and whirl it ever lest haply it may catch the breezes of popular applause; and their shrieking cries somewhat drown the steady tones of the true prophet. But the shrillness of the charlatan passes soon into hoarseness, and the hoarseness into a husky whisper, and the whisper into discredited silence, whilst the tones of the true prophet grow louder and clearer as time goes on; and the more men find his warnings to have been wanted and his actions to have worked for practical good, the more do his tones become reinforced by the commending and endorsing expressions of his fellows. Without allowing a not inconsiderable space of time to expire before giving an account of so full and energetic a career as that of Thomas Wakley, no adequate and impartial view of the man could be taken. A mountain cannot be seen from its side or even from its base, some little peak, some unimportant excrescence of the outline obscures the whole view. We must get to a distance. Just so with these big and busy careers, they cannot be judged during their course, and they cannot be summed up at their immediate close; distance—a long distance—of time must be allowed to elapse before the manner of life that has been led, and the amount of good, or it may be ill, that the world has reaped therefrom can be estimated. But then the task becomes easy, and in some ways the longer the delay the easier, for time will have sifted the wheat from the chaff, and the harvest can be accurately gauged. This is eminently the case with such a man as Thomas Wakley, the medical reformer. Time tells his story. We have only to say how things were when he arose and how he treated them, all of which is a matter of public history, and then to refer to things as they are now, one-third of a century after his death, to be in a position to judge of his life-work.

This brief and bald sketch of the life of Thomas Wakley must be looked upon as a skeleton of the biography that is to appear in ensuing numbers of THE LANCET—it is the bones over which the various tissues of a complex organisation will be laid, and it is hoped that to those who know nothing of the man or his history it will prove a stimulant to curiosity. We are certain that many must feel as they read the following schedule of his work, with an indication of the conditions under which he did it, that the medical profession must owe him an immense debt. We who live in peaceful times, and for whom the medical career is ordered by a properly authoritative and in a way representative Council upon a sound and sensible basis, have a difficulty in understanding the evil plight of the medical man some seventy years ago, but it is particularly necessary that the reader should have some appreciation of the reality and gravity of the abuses that were rife in the profession at the time of the foundation of THE LANCET that he may judge rightly of the course taken by Thomas Wakley in his successful efforts towards reform. Without such appreciation the vigour of his actions and language might be misinterpreted, and the stupendous nature of his task be underrated.

The following passage out of a letter from Sir John Erichsen will show that we are not alone in our views; and, roughly speaking, the object of the biography is so to place its subject before our readers that they may regard Thomas Wakley in the same light that he does. Sir John Erichsen's words are the thesis which the ensuing chapters will prove:—

"6, Cavendish-place, W.,
"Nov. 23rd, 1895.

"DEAR SIRS,— * * * * * * * * I am glad to hear that you are about to publish a biographical sketch of Mr. Wakley on the occasion of the centenary of his birth. The present generation of medical men know little of him, and are for the most part ignorant of how much they owe to him for exposing and fearlessly attacking the manifold abuses that existed in every department of the profession, in the colleges, hospitals, and medical schools, in the first third of this century. Corruption, jobbery, nepotism, promotion by purchase were rife in the colleges and hospitals, and medical education was at a low ebb when Wakley entered on his career as a journalist. By his outspoken and fearless denunciations of these abuses he brought about their reform, and so cleared the road to fame and fortune for those members of the profession who had to rely solely on their own ability and power of work. It was, in fact, Mr. Wakley who made a William Jenner or an Andrew Clark possible. I know no better or more interesting reading than is to be found in the earlier columns of THE LANCET. To any young physician or surgeon who wishes to know something of the past history of his profession I would recommend them as giving him an insight into the condition of his profession sixty or seventy years ago. For force of argument, vigour, and vivacity of style, and keenness of satire, its leaders and articles communicated by Wardrop and others are unsurpassed. And the reader, if not the possessor of a long purse or the nephew of an all-powerful uncle, will rise from their perusal with a feeling of deep gratitude to Mr. Wakley as the man who had cleared away those obstacles that would otherwise have

Digitized by Google

barred the way to success in life, and by no one is that feeling more cordially entertained than by,

"Dear Sirs, yours most truly,

"JOHN ERIC ERICHSEN.

"To the Messrs. Thomas Wakley, Sen. and Jun."

Thomas Wakley was born on Nov. 27th, 1795, at Membury, in Devonshire, being the eleventh and youngest child of his father, a considerable land-owner in the county, and a well-known authority in agricultural matters not only locally but outside his immediate neighbourhood. His home did not see much of him. After being for some little time—a very little time—at the Grammar School at Chard, he made a sea-voyage to Calcutta upon an East Indiaman as a kind of supercargo. The captain under whom he sailed was a friend of the family, and the journey seems to have been rather a pleasure trip undertaken with the permission of his friends in response to his ardent wish than a serious beginning to a professional career as a sailor. The captain died on the voyage and Thomas Wakley returned home, and was sent to another school in his native county, the Wiveliscombe Grammar School, and thence after two years of study entered upon his articles to an apothecary at Taunton—one of the old school in practice before the Act of 1815, and content to style himself an "apothecary and man-midwife." This was in those days the usual method of entering upon the profession of medicine, and the articles were a regular form of indenture—the binding over of an apprentice. He did not complete his time with his original master, but spent his seventeenth and the two following years as pupil, partly to a Mr. Coulson, of Henley-on-Thames, and partly as assistant to his brother-in-law, a Mr. Phelps, who was in general practice at Beaminster, in Dorsetshire. And in 1815 he came to London to "walk the hospitals." And what a chaotic condition the profession was in at the time will appear in the course of this biography—for at the risk of repeating ourselves it must again be said that this preliminary sketch is intended only to be a bare record of facts—but no doubt young Wakley's friends chose wisely for him in sending him to study at the school of the United Hospitals of Guy's and St. Thomas's, a school over which Sir Astley Cooper reigned supreme.

Almost immediately his critical faculty, always, as we shall see, developed to an enormous extent and exercised with a vigour amounting to pugnacity, began to manifest itself. Although nominally a student at the united schools, he began wandering about London, attending the classes of the various lecturers at various schools to see who was the person most fitted to impart instruction—who had th gift of teaching, of illuminating the subject upon which he was speaking; and who were the teachers to be avoided—the wordy, the diffuse, and the unpractical, of whom at that time and under the corrupt conditions prevalent there were many. And he was right in his judgment to an astonishing extent, to such an extent that in the year of the battle of Waterloo he had formed much the same opinion as to the value of lectures and lecturers that we are in the habit of accepting as universal opinion now. He decided that harangues, however eloquent and honest in endeavour, upon such subjects as anatomy, chemistry, and materia medica, unless accompanied or supplemented by a practical course of demonstration, must be useless to him, and he would have none of them. Surgery and medicine with hospital practice, materia medica with dispensing, anatomy with dissecting, he saw would constitute a practical education, but separate the theory from the practice and the one became a useless source of tedium and the other an opportunity for idle horse-play. Yet so bad was hospital administration in those days that the education of the student had to be conducted in a scrappy manner. How could Sir Somebody Something's lectures be made clear to the student by observation of his practice when no student knew on what day or at what hour the eminent baronet might appear at the hospital, when the diagnosis at which he had arrived was not communicated to anyone, when the treatment—not only its *rationale* and its results—but the bare treatment was known only to his clinical assistants? These were the things that were so terribly obvious to the shrewd country lad's eye, and these were the questions that while still in a state of pupilage he was wont to ask angrily, and to say that some day they would have to be answered. And the attitude is a remarkable example of precocity. For consider! Here is a country lad, brought up on a western farm, educated at a local grammar school, apprenticed in a small provincial town, who comes to London to begin his professional career amidst new and imposing surroundings, where his eyes are filled with strange sights, while his ears are made to ring with stories of the surgical prowess of this great man, the medical finesse of that, the wealth of another, and the importance of all the professional figureheads. For there is no such hero-worshipper as your medical student, and the great men of those days lost nothing in the estimation of their following by the fact that they had now and again attained to their positions under corrupt systems. But this lad is not carried away. He calmly walks from one great man to another, appraises them to find more than one wanting, and even where he does not withhold approbation of an individual finds the system under which the work is done or the lectures delivered a rotten one, and does not scruple to say so. It is not often that a beginner in a profession, one whose foot is barely upon the threshold, starts with an indictment of the whole framework of that profession. And if he does, his fault-finding is generally the outcome of meaningless spleen, proved from the beginning to be groundless. But Thomas Wakley's first boyish impressions of the medical curriculum were in the main correct, and even in detail remarkably free from error; and he proved their correctness later and lived to see the abuses which were so clear to his boyish gaze reformed in large measure by his own act and pen.

In 1817, having taken the diploma of the Royal College of Surgeons of England, Mr. Wakley turned his thoughts to practice. The conditions under which the profession lay, every whit as much as his declared proclivities, precluded him from thinking of a career as a hospital surgeon, with its emoluments of lecturer's and examiner's fees. He had not the necessary introductions, he was without the necessary spirit of surgical research, and he had in him not one whit of the pliability which allows a man to adopt a career not particularly to his taste for the sake of possible worldly success. Men and women, their lives and natures, appealed to him, and he started in practice among the poor with a desire to alleviate their sorrows that was quite independent of any desire to extend his own scientific knowledge. At the beginning of the year 1820 his future father-in-law bought for him an old-established practice in the neighbourhood of Oxford-circus on the occasion of his approaching marriage. The house stood in Argyll-street, Regent-street, as nearly as may be upon the present site of Hengler's circus. Here he brought his wife, to whom he was married on Feb. 6th, 1820. Miss Goodchild was the daughter of a wealthy man, and in after years Mr. Wakley made no secret of the fact that in many of the stormy crises of his life—and he was not long before he began courting the storms—the long purse and strong ready assistance of his father-in-law kept him from foundering.

Within six months of their marriage a terrible misfortune overtook the young couple—the house in Argyll-street was destroyed entirely by fire. Mr. Wakley and two of his servants barely escaped with their lives, and all their furniture and Mrs. Wakley's jewelry—she had recently been

Digitized by Google

the recipient of some handsome wedding presents—perished in the conflagration or was stolen. Mrs. Wakley, by good fortune, was away from home at the time staying with her father. This does not, however, tell the tale of their troubles. The remarkable circumstances under which the fire occurred were alleged by the insurance company to be such as to entitle the company to withhold compensation, while the wildest stories derogatory to the probity of the luckless owner of the house were rife. Mr. Wakley brought an action against the company, and recovered the whole sum that was owing as well as mulcting them in costs, but until the case was decided all along the line in his favour he was placed by cruel slanders under a heavy cloud of suspicion. The true story we shall tell at length in an early chapter of the biography. It is sufficient here to state that no one who knew him ever listened to the evil reports, while he himself was so absolutely careless of the opinion of any who were not personally known to and respected by him that he made no vigorous protests. He vindicated himself in the law courts and laughed at the libels.

During the next two years he practised his profession, but his heart was not in his occupation. He was a big man, and he felt that there had grown up within him the capability to do a big work. He was a born reformer and an eloquent propagandist, and the routine of practice stifled him. It was not his profession that he disliked—he was absolutely devoted to the science of medicine—it was that, burning with righteous indignation at the many abuses existent in that profession, he felt that he could serve it better as a reformer than as a general practitioner. Such impulses counted for almost everything in deciding him to take the extreme step of leaving the profession to enter upon a systematic attempt to set aright the abuses; but we have it on personal record from himself that it was the wish of his young wife that actually precipitated him upon the course with which his name will ever be associated. Mrs. Wakley had taken an objection to his remaining in practice and found his resolve to leave it most welcome, so that, no sooner was his scheme formulated so far that he could speak of it to his friends of a like way of thinking, than he found himself encouraged to persevere in it in the very quarter where he might have expected opposition. It was almost as much due to the future editor's respect for his wife's wishes as it was to his own burning desire for reform that THE LANCET owed its origin.

On Oct. 5th, 1823, a Sunday, the first number of THE LANCET was issued, prefaced with a declaration of war and teeming with contentious matter. The preface said that as it had long been a subject of surprise and regret that there existed no channel for conveying to the public, to practitioners, and to medical students reports of the lectures at the hospitals of London, and that as Sir Astley Cooper's lectures on surgery were probably the best in Europe, the new journal would publish them as they were spoken. A report of clinical cases all over the world was also promised. The resistance to publicity that followed in so many directions was foreseen in the following words, and the treatment that it received was also prophesied: "We are well aware that we shall be assailed by much *interested* opposition; but we will fearlessly discharge our duty." As to the literature of the first volume, we need here only refer to one item of the contents, a lecture delivered by Sir Astley Cooper in the theatre of St. Thomas's Hospital, for its publication may be taken as the purest type of the sort of work that the editor had before him as the ideal of his duties. Sir Astley Cooper was the leading light of surgery in England. He was also a magnificent supporter of the then prevailing methods of nepotism by which the valuable and honourable appointments of the metropolitan hospitals were too frequently held by unworthy representatives of the profession. The combined staff of St. Thomas's and Guy's, at that time known as the United Hospitals, contained several close relatives of Sir Astley Cooper, and it is not exaggerating to say that he had had a voice in the election of all his juniors. The young journalist's shrewd idea of a first step towards reform would have been voiced by himself as follows: I will publish the lectures of the hospital surgeons and physicians to their classes; if they are good, so much the better for the profession at large and those hoping to join the roll; if they are bad the profession at large will see that they are being taught by men who are unfit to hold the posts for which they are paid, and will as a consequence recognise that the existent systems of election are corrupt. It was characteristic of his methods of thought that he never seems to have considered whether he had a legal right to publish the lectures in that way at all, a question that was eventually settled in his favour after prolonged litigation with the celebrated Abernethy. It was also a good example of his fairness in the midst of his enthusiasm that he should have selected Sir Astley Cooper as his first "victim," for that is how the authors of the reported lectures were wont to describe themselves. Sir Astley Cooper was a splendid lecturer, with enormous experience to draw upon, and a happy, lucid manner of expressing himself, so that the issue of his lectures was a real boon to the profession. Had Mr. Wakley been the pure iconoclast that he was represented to be—and iconoclast, we may add, is far too mild a word, for a section of the profession at that time, in their fright, spoke of him in terms that could have fitly been applied to a Malay running amok—he would not have selected as a specimen lecturer belonging to the privileged classes his old and brilliant teacher. He would have selected a bungler—there were such—and would have reported him and criticised him simultaneously. But he desired to *in*form as much as to *re*form, and whatever his legal position might have been in the matter, the great value that the publication of such lectures was to the medical world is beyond all doubt.

From this time forward for ten years the pages of THE LANCET were the duelling ground for a series of fierce encounters between the editor and the members of the privileged classes in medicine. Lectures and debates at the medical societies were reported, to the exasperation of the lecturers and the speakers, and the delight of the profession at large and the students. As a natural pendant to the editorial assertion that the elections to the staffs of the various metropolitan hospitals were made at the instigation of gross nepotism, accounts were given in the pages of THE LANCET of maladministration in the various schools and malpraxis in the various wards. And upon these came actions and cross-actions. These will be narrated at length in subsequent chapters. It is sufficient to state here that six actions were brought against him, the aggregate sum of £8000 being claimed for damages. Of these actions he lost four—£50 being awarded to Mr. Tyrell, £5 to Dr. Macleod, one farthing to Dr. Ramadge, and £100 to Mr. Bransby Cooper. This last sum, together with £400 costs, was collected by public subscription, so that his fearlessness being justifiable cost him but little. The criminal action brought against him by the Royal College of Surgeons of England, and the action brought against him by Mr. Guthrie were both abandoned by the plaintiffs in his favour. On the other hand Mr. Wakley, who never dropped his methods of outspoken speech, brought six actions for libel as plaintiff, and won them all. On most of these occasions he conducted his own case, often against the most powerful advocates of the day, engaged at enormous fees, and in one, the most sensational case of all, that of Cooper *v.* Wakley, he actually began by upsetting Sir James Scarlett, afterwards Lord Chancellor Abinger, on a point of law. His wonderful success had this effect—

Digitized by Google

it gave him a right to free speech which he exercised to the wholesome dread of all pretenders, while it made his enemies, and they were many, cautious.

His attitude towards the Royal College of Surgeons of England is another subject which will require so much description later that it is unnecessary to do more than allude to it here. In the year 1826, at a large meeting promoted by Mr. Wakley, and presided over by Mr. (afterwards Sir William) Lawrence, a resolution was passed condemning the examinations of the College as perfectly ridiculous as a test of qualification; and both before and after that date the columns of this paper teemed with uncomplimentary allusions to the constitution and government of the corporation. Things have greatly changed now, though our readers well know that, in our opinion, they might still change with advantage, but the place that Mr. Wakley assumed in the fiercer struggles of olden times was the place he always chose when once he had made up his resolute mind upon the rights and wrongs of a matter. He fought in the van, and was responsible for the discontinuation of many of the humiliations to which the Members of that day were subjected at the hands of their governing body.

In 1830 Mr. Wakley, who had always been impressed with the necessity of a coroner having had a medical education, and had repeatedly insisted upon this in these columns, became a candidate for the coronership of Middlesex. There were many circumstances that combined to make this election particularly exciting and ruinously expensive, and Mr. Wakley's candidature proved unsuccessful. In those days all the Parliamentary free-voters had a vote for the county, and as the poll was kept open for a week the attendant expenses were enormous. This unsuccessful attempt cost Mr. Wakley no less than £8000, but it paved the way doubly for his future success. On the one hand, the arguments in favour of the tenure of coronerships by medical men were brought before the public in a forcible manner, were discussed and rediscussed, and, as time has shown, were found to be sound. On the other hand, the severity of the contest—Mr. Wakley registered 3534 votes and his successful opponent but 3670—made calls upon Mr. Wakley's powers of oratory, to which he responded in a manner that astounded his friends and is even said to have surprised himself. That he was a clear-headed man, able to say what he thought and write what he knew in a way that conveyed no doubt of his meaning or his sincerity were matters by this time of common notoriety, but that he possessed the magic power of holding a large audience, of carrying it with him in his sentiments, of playing with its finer feelings while dominating its coarser, that, in short, he was a true orator and not a mere enthusiastic speech-maker, was unknown to the public and unknown to himself until he began to address the freeholders of Middlesex in search of their suffrages for the coronership. As a result of his remarkable displays of eloquence, when he presented himself again to the freeholders of Middlesex in 1839 he was elected coroner by an enormous majority; while the eyes of the Radicals were turned with attention upon the possessor of qualities that would be so useful to their party. Mr. Wakley held the post of coroner until the close of his life—indeed, the last communication received from him to our pages was a message from Madeira saying, with the hopefulness so often associated with the condition of health that he was then experiencing, that in a few weeks he expected to be back to continue his duties. Of his conception of those duties and of the way that he discharged them we shall frequently have occasion to give examples. The memorable Hounslow case, where an unfortunate private soldier died from the results of flogging, called forth a verdict under his direction which set England ablaze; his professional brethren have never ceased to thank him for his untiring efforts to place medical evidence upon a proper basis; while such heterogeneous testimony as that of Dickens, Douglas Jerrold, the matter-of-fact electors of Middlesex, the serious columns of the *Examiner* and the *Spectator*, and the comic columns of *Punch* could be adduced to show that his courage, zeal, and industry as a coroner were widely recognised.

On the passing of the Reform Bill in 1832, and as a direct result of the eloquent electoral campaign that he had conducted in first seeking the office of coroner, he received a requisition from a large body of the electors of Finsbury that he would offer himself as a candidate to represent them in Parliament. He accepted, but was unsuccessful, as he was also at a second election that immediately followed. But in 1835 he obtained a majority of upwards of 1000 votes, and from that day represented the borough until his retirement in 1852. During all this long period he infused into his Parliamentary duties the same impetuous enthusiasm that marked his early crusades in the cause of medical reform. He was a frequent and powerful speaker, shrewd, sensible, and humorous, sarcastic sometimes, pathetic sometimes, but always direct and convincing. He entered the House a declared and uncompromising Radical, with a platform manner, a contempt for forms, and an Ishmael's reputation; he was re-elected to the House as a recognised voice in the more Liberal counsels of his country, as an orator, an accomplished parliamentarian, and the personal friend of the leaders of his school of thought. While in the House he used every opportunity that offered itself of upholding the rights of his medical brethren. He framed and carried the Medical Witnesses Act, the effect of which was to put in the pocket of the profession many thousands annually of properly earned remuneration. He obtained a Select Committee of the House of Commons to inquire into the state of medical education and practice, whose report had great influence upon the cause of reform in the profession; and many of his speeches upon the status of the medical corporations, and the desirability of medical coronerships show that in the larger sphere of constitutional duty he ever remembered the cause of his profession. His finest oratorical effort was also one of his earliest—a speech calling upon Lord Grey to commute the sentences of certain Dorchester labourers condemned to penal servitude for illegal combination. The speech was received with unbounded applause on both sides of the House, and will be seen, when we reproduce it in full, to be a remarkably eloquent exposition of liberal humanitarianism. If this speech was not convincing to the House, it was to the country at large, and that was the audience to which he was really addressing himself.

The rest of his public life is written in the columns of this, his paper. He instituted or supported the following Bills among many, or spoke and wrote ceaselessly concerning them:—The Medical Stamp Act (1829), A Bill for the Publication of Lectures (1835), and a Bill for the Remuneration of Medical Witnesses (1836),[1] while he resisted with effect many propositions for legislation that he considered detrimental to the public health of the nation or the well-being of the profession. He inaugurated and largely carried out remarkable reforms in the Poor-law, effecting the dismissal of incompetent officers, espousing the cause of the pauper lunatic, and sitting upon a Select Committee of the House of Commons appointed, as a result of his own motion, to inquire into the efficiency of the treatment provided for the sick poor in the parochial unions. He inaugurated an inquiry into the food of the country, the result of which he published in THE LANCET,

[1] These dates refer to Mr. Wakley's articles in our columns, and do not signify the passage of the Acts in question.

Digitized by Google

the articles being the forerunners of the series which we still continue to issue under the generic title of THE LANCET Special Analytical Sanitary Commissions. "We have undertaken," he said, "a task large enough to engage the attention of the Government of this country. With the exception of officers to observe and report upon diseased meat or fish the public authorities take no cognisance of the adulteration and poisoning by the slower but equally sure mode of adulteration of foods and drinks. We will bring the microscope and the test-tube to bear with unerring truth upon things hidden and secret to the unaided senses." This programme was exhaustively and fearlessly entered upon, and there is no doubt that the Act of 1875, under whose working the use of adulterants injurious to health has practically ceased and the practice of fraudulent adulteration been greatly reduced, was the outcome of the ruthless exposures commenced in these columns twenty years previously.

The foregoing must suffice for a sketch of the life-work of Thomas Wakley. In 1860, towards the close of the year, he began to suffer severely from a cough, with much expectoration and occasional hæmoptysis. In January, 1861, he had to own himself an invalid, and repaired to Brighton to place himself under Dr. Alfred Hall, who had previously had the care of his wife in her last illness. He returned to London in the spring in a much better state of health, but hæmoptysis recurring he left under medical advice in the autumn of the same year for Madeira. He there rallied considerably, the emaciation was arrested, and he seemed to be gaining strength. Early in May, however, the hæmoptysis recurred, and on the 16th of that month he died.

It is the task of developing the foregoing sketch into an adequate biography that lies immediately before us. We hope that our readers will recognise from this outline that it is a fitting and proper task to be undertaken in these columns, inasmuch as we shall prove beyond all cavil that to the efforts of Thomas Wakley much of the material prosperity of the medical profession of the present day is due and much of the importance that the medical man occupies in the opinion of his fellow-citizens; for the healing sciences have been as much advanced by the man who made adequate medical education and proper chances of advancement possible for the poorest aspirant as ever they have been advanced by the test-tube of the *savant*, the beneficence of the plutocrat, or the golden eloquence of the gifted lecturer.

We shall be exceedingly grateful to anyone who can give us information that will be of service to us in the preparation of the forthcoming biography. Letters should be addressed to the Messrs. Wakley, and all documents will be carefully filed and returned when used. We take this opportunity of cordially thanking the numerous gentlemen who have already written to us, it having been impossible to reply to all.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE half-yearly meeting of Fellows will be held on Jan. 2nd, 1896, at 4 P.M. The following are the agenda on the notice paper:

To read the minutes of the half-yearly meeting of Fellows on July 4th last (an abstract of this meeting was published in our issue of July 13th).

Motion that the President do sign the minutes as being correct.

The President to report that the committee appointed by the Council to receive deputations from the Fellows in reference to the desirability, or otherwise, of applying for a new Charter had received one deputation of Fellows; that the committee had also, by direction of the Council, received a deputation of Members in reference to the same matter; that the committee had further been instructed by the Council to report upon certain resolutions carried at the annual meeting of Fellows and Members on the 7th ult., but that, as one of those resolutions was submitted to the meeting of Fellows to-day for consideration, the committee had thought it desirable to postpone their report to the Council.

To read the following resolution carried at the annual meeting of Fellows and Members on the 7th ult., and referred by the Council to the consideration of this meeting of Fellows, viz.: "That the number of the Council be increased to thirty-two, and that eight of these, who may be Members, shall be elected by the Members only, provided always that no Member who has not been a Member for twenty years shall be eligible for a seat on the Council." Proceedings thereon.

Mr. Herbert W. Page to move: "That it is desirable to give to the Members of the College direct representation upon the Council, and that for this purpose the number of seats on the Council shall be raised to twenty-eight, of which four shall be filled by eligible Fellows, who shall be elected by the votes of Members only, in such a manner and at such time as the Council may determine."

Mr. R. Clement Lucas to move: "That, in the opinion of the Fellows of this College, women should be admitted to the diplomas of the College."

Mr. Timothy Holmes to move: "That this meeting learns with pleasure that the Council of the College are represented on the Civil Rights Defence Committee in the case of Mr. R. B. Anderson."

Mr. C. H. Golding-Bird to move: "That the Council be requested to consider the advisability of changing the date of the winter meeting of the Fellows to the first Thursday either in December or February from the first Thursday in January."

There can be no doubt that the first Thursday in January is a very inconvenient date for the half-yearly meeting, coming as it does in the midst of the holidays and festive season when few are inclined to make sacrifices for such a purpose as this. It requires at any time a strong inducement for medical practitioners to concern themselves with medico-political questions, and the facilities afforded for discussion at the College are not such as to tempt anyone to put himself out of the way to attend the meetings either of Fellows or of Fellows and Members. On Jan. 2nd we trust that the unusually interesting and important programme will attract many who would otherwise have stayed away, and that the representation of the Members of the College, the claims of women to admission to the diplomas, and the wrongs of Mr. R. B. Anderson will receive the consideration which they all deserve. We would therefore urge upon all Fellows who can possibly attend that they should sacrifice their social enjoyments for the good of the College and make a point of helping to fill the benches of the theatre on Jan. 2nd, 1896.

THE PUBLICATION OF PAPERS READ BEFORE THE ROYAL SOCIETY.

WE have received the following letter from Professor Michael Foster, senior secretary to the Royal Society, with a request for its publication:—

"Shelford, Cambridge, Dec. 21st, 1895.

"DEAR DR. PAVY,—I have to acknowledge the receipt of your book entitled 'The Physiology of the Carbohydrates, an Epicriticism,' which you have done me the honour to send me. I have carefully read the preface, the appearance of which has set me free to say in regard to myself what could not be said in official correspondence. I have the leave of the President of the Royal Society to state that since your first letter to them the President and Council have received legal advice confirming your contention that in taking steps with regard to the publication of Dr. Paton's paper before it was read they acted in contravention of the statutes. In their anxiety to shorten the delay, always in part unavoidable, attending the publication of papers they have been led, not only in the case of Dr. Paton's paper, but also in many other cases during recent years, to adopt a mode of procedure which they now learn contravenes the statutes; but they have decided on taking steps so to amend the statutes as to remove a limitation which, in the interests of the Fellows and of science, is clearly undesirable. This point conceded,

Digitized by Google

the whole of the rest of the action taken in regard to Dr. Paton's paper was conformable to the statutes. The President and Council, sitting as Committee of Papers, authorised the officers to 'refer' papers during the recess, and under this authority Dr. Paton's paper was referred to certain Fellows of the Society, who, since they were 'knowing and well skilled in the particular branch of science to which the said paper' related, seemed likely to have been chosen referees by the Committee of Papers had it been sitting. The reports being favourable, the paper was, under a like authority, ordered for publication in accordance with the reports. This action of the officers, being reported to the Committee of Papers at its first meeting after the recess, was approved and confirmed. By that decision the President and Council sitting as Committee of Papers took from my brother officers and myself all responsibility. Had the President and Council thought that the referees had been unwisely chosen it was in their power—and was, indeed, their duty—to undo what had been done and to reconsider the question of publication. They did not do so.

I at once and freely accept your explanation that by the words 'contrary to what is considered ethically becoming' contained in your first letter you meant 'biassed.' Will you allow me to say that I fully recognise the grave responsibilities attaching to my office of senior secretary to the Royal Society and the injury to science attending on a 'biassed' action on my part. No man is free from 'bias,' and my action has at times, probably often, been other than it should have been. But, so far as I know, I have not consciously allowed myself to be unduly influenced by personal considerations save, perhaps, when I have urged against the hostile criticism directed towards some communications made to the Royal Society that these should be judged not only in respect to their absolute value, but also with regard to the position and reputation of the authors. The last paragraph in your preface embodies a suggestion as to the nomination of the referees on Dr. Paton's paper, which I venture to hope you would not have published had you fully realised that, refereeship being strictly confidential, I am prevented from making any answer whatever to it. Your preface being a public matter, I shall send a copy of this letter to the medical papers, and in conclusion let me ask you not to think me discourteous in desiring not to continue the correspondence.

"Yours faithfully,

"Dr. Pavy, F.R.S., &c." "M. FOSTER.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5925 births and 3774 deaths were registered during the week ending Dec. 21st. The annual rate of mortality in these towns, which had been 17·9 and 17·8 per 1000 in the two preceding weeks, rose again last week to 18·6. In London the rate was 18·1 per 1000, while it averaged 18·9 in the thirty-two provincial towns. The lowest rates in these towns were 11·8 in Brighton, 12·8 in Portsmouth, 13·0 in Derby, 13·6 in Croydon, and 13·9 in Bristol; the highest rates were 21·8 in Oldham, 23·0 in Birmingham, 23·1 in Wolverhampton, 24·3 in Salford, and 27·5 in Liverpool. The 3774 deaths included 593 which were referred to the principal zymotic diseases, against 561 and 524 in the two preceding weeks; of these, 250 resulted from measles, 101 from whooping-cough, 97 from diphtheria, 57 from "fever" (principally enteric), 51 from scarlet fever, 47 from diarrhœa, and not one from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Swansea, Derby, Preston, and Halifax; the highest rates in Birkenhead, Birmingham, Liverpool, Norwich, and Salford. The greatest mortality from measles occurred in London, Leicester, Birmingham, Norwich, Blackburn and Salford; from scarlet fever in Salford; from whooping-cough in Plymouth, Bradford, Leicester, Birkenhead, and Leeds; and from "fever" in Salford, Norwich, Sunderland and Birkenhead. The 97 deaths from diphtheria included 62 in London, 6 in Birmingham, 5 in Liverpool, 4 in Manchester, 4 in Newcastle-upon-Tyne, and 3 in Sheffield. No fatal case of small-pox was registered during the week under notice, either in London, or in any other of the thirty-three large towns. There were 82 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 21st inst., against 79, 87 and 89, at the end of the three preceding weeks; 5 new cases were admitted during the week, against 9, 18, and 18 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2725, against 2799, 2805, and 2800 on the three preceding Saturdays; 210 new cases were admitted during the week, against 325, 312, and 329 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 264 in each of the two preceding weeks, rose again to 291 last week, but were 214 below the corrected average. The causes of 46, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Leeds, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Birmingham, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·5 and 18·9 per 1000 in the two preceding weeks, rose again to 19·2 during the week ending Dec. 21st, and exceeded by 0·6 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Perth, and 15·7 in Paisley to 19·8 in Aberdeen and 33·5 in Greenock. The 553 deaths in these towns included 23 which were referred to whooping-cough, 17 to measles, 13 to scarlet fever, 11 to diphtheria, 11 to diarrhœa, 8 to "fever," and not one to small-pox. In all, 83 deaths resulted from these principal zymotic diseases, against 67 and 68 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·9 per 1000, which corresponded with the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased from 10 to 24 in the four preceding weeks, were 23 last week, of which 15 occurred in Glasgow and 4 in Aberdeen. The 17 deaths referred to measles showed a further increase upon the numbers recorded in recent weeks, and included 10 in Greenock and 7 in Glasgow The fatal cases of scarlet fever, which had been 8 in each of the three preceding weeks, rose to 18 last week, of which 5 occurred in Glasgow, 3 in Edinburgh, and 2 each in Aberdeen and Leith. The fatal cases of diphtheria, which had been 10 and 5 in the two preceding weeks, rose again to 11 last week, and included 5 in Edinburgh, 2 in Leith, and 2 in Glasgow. The 8 deaths referred to different forms of "fever" exceeded the number recorded in any recent week, and included 6 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 132 and 97 in the two preceding weeks, rose again to 103 last week, but were 39 below the number in the corresponding week of last year. The causes of 39, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·1 and 22·8 per 1000 in the two preceding weeks, further increased to 25·1 during the week ending Dec. 21st. During the past twelve weeks of the current quarter the death-rate in the city has averaged 24·1 per 1000, the rate during the same period being 18·1 in London and 17·2 in Edinburgh. The 168 deaths registered in Dublin during the week under notice showed an increase of 15 upon the number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against 6 and 8 in the two preceding weeks; of these, 3 resulted from "fever," 2 from diarrhœa, 1 from scarlet fever, 1 from diphtheria, 1 from whooping-cough, but not one either from measles or small-pox. These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 3·3 in London and 2·7 in Edinburgh. The deaths referred to different forms of "fever," which had been 4, 1, and 3 in the three preceding weeks, were again 3 last week. The mortality from diarrhœa showed a slight decline, while that from diphtheria and from whooping-cough corresponded with that recorded in the preceding week. The 168 deaths in Dublin last week included 29 of infants under one year of age, and 41 of persons aged upwards of sixty years; the

Digitized by Google

deaths both of infants and of elderly persons slightly exceeded the numbers recorded in the preceding week. Three inquest cases and 1 death from violence were registered; and 65, or more than a third, of the deaths occurred in public institutions. The causes of 18 or nearly 11 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

THE following officers will retire in 1896:—Surgeon-Major-General Sir W. A. Mackinnon, K.C.B., Director-General, Surgeon-Major-General J. Colahan, Surgeon-Major-General H. F. Paterson, Brigade-Surgeon-Lieutenant-Colonel H. J. O'Brien, Brigade-Surgeon-Lieutenant-Colonel J. Barry, and Surgeon-Lieutenant-Colonel A. Kirwan.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotions among the officers of the Indian Medical Services:—*Bengal Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels (dated Sept. 30th, 1895): Patrick Alexander Weir, Peter Johnston Freyer, M.D., Percy de Haga Haig, John Lewtas, M.D., and John O'Neill, M.D. Surgeon-Captains to be Surgeon-Majors (dated Sept. 29th, 1895): James John Pratt and Robert Shore, M.D. *Madras Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels (dated Sept. 30th, 1895); Edward Ferrand and Francis Hoskins Pedroza. Surgeon-Captains to be Surgeon-Majors (dated Sept. 29th, 1895): William Burney Bannerman, M.D., and Henry Thomson. *Bombay Medical Establishment:* Surgeon-Majors to be Surgeon-Lieutenant-Colonels (dated Sept. 30th, 1895): John Wilkins Clarkson and Joseph Parker, M.D. Surgeon-Captain to be Surgeon-Major (dated Sept. 29th, 1895): Carrapiet John Sarkies. The Queen has also approved of the retirement from the Service of the undermentioned officers:—*Bengal Medical Establishment:* Brigade-Surgeon-Lieutenant-Colonel Henry Black Purves (dated Dec. 4th, 1895), and Surgeon-Lieutenant-Colonel William Michael Courtney (dated Dec. 7th, 1895).

NAVAL MEDICAL SERVICE.

Fleet-Surgeon James William Hambly Hawton has been placed on the Retired List of his rank at his own request (dated Dec. 9th, 1895).

VOLUNTEER CORPS.

The following members of the Volunteer Ambulance School of Instruction have recently passed the proficiency examination for Volunteer Medical Officers conducted by the Army Medical Staff at the headquarters of regimental and other districts thus earning the higher grant for their corps and becoming entitled to promotion after completing the necessary period of service:—Surgeon-Lieutenant-Colonels: F. W. Humphreys, V.D., F.R.C.S., 15th Middlesex (The Customs and Docks) Rifle Volunteers; T. R. Pearson, V.D., M.D., 1st North Riding of Yorkshire Volunteer Artillery; A. Wilson, V.D., 2nd Volunteer Battalion Northumberland Fusiliers. Surgeon-Majors: T. F. Fleetwood, M.B., F.R.C.S.I., Victorian Military Forces, South Australia; F. Orton, M.D., 3rd Middlesex Rifle Volunteers. Surgeon-Captains: D. Stewart, 1st Volunteer Battalion Northumberland Fusiliers; H. G. Ashwell, Robin Hood Rifle Volunteers; W. R. Wood, M.A., M.D., 1st Volunteer Battalion Cheshire Regiment; H. Marriott, M.B., 4th Volunteer Battalion Cheshire Regiment; R. Batterbury, M.D., 2nd Volunteer Battalion Bedfordshire Regiment; H. J. Mackay, M.D., 2nd Volunteer Battalion Wiltshire Regiment; J. W. Hodgson, 1st Devonshire Volunteer Artillery; J. S. Forrest, 2nd Northumberland (Percy) Volunteer Artillery. Surgeon-Lieutenants: P. M. Yearsley, F.R.C.S., 16th Middlesex (London Irish) Rifle Volunteers; G. Herschell, M.D., M.R.C.P., 22nd Middlesex (Central London Rangers) Rifle Volunteers; F. J. Warwick, M.A., and A. C. Tunstall, M.D., F.R.C.S., Bearer Company East London Volunteer Brigade; T. Brushfield, M.D., and F. Hird, Bearer Company Surrey Volunteer Brigade; R. E. South, 2nd Volunteer Battalion Lincolnshire Regiment; S. A. Mugford, 2nd Volunteer Battalion Essex Regiment; G. McIntyre, M.B., 4th Volunteer Battalion Scottish Rifles; G. H. Ward-Humphreys, 1st Gloucestershire Volunteer Royal Engineers; H. W. Laing, M.D., 1st Fifeshire Volunteer Artillery; T. Forrest, M.B., 3rd Lanarkshire Rifle Volunteers; W. J. Sprott, M.D., Robin Hood Rifle Volunteers; J. J. O'Hagan, M.B., 5th (Irish) Volunteer Battalion the King's Liverpool Regiment; K. W. I. Mackenzie, 5th (Isle of Wight Princess Beatrice's) Volunteer Battalion the Hampshire Regiment); R. Jackson, M.B., 2nd Lancashire Volunteer Royal Engineers; J. H. Stacey, 1st Volunteer Battalion Norfolk Regiment; J. B. Stevens, 2nd Volunteer Battalion (Princess Louise's) Argyll and Sutherland Highlanders; R. P. Mackenzie, M.B., 1st Shropshire and Staffordshire Volunteer Artillery; W. A. Pond, M.A., M.D., M.R.C.P., 2nd London Rifle Volunteers; A. Thorne, 1st Cinque Ports Rifle Volunteers; C. Vise, M.D., 1st Volunteer Battalion the Queen's Own Royal West Kent Regiment; R. Odell, 1st Volunteer Battalion Bedfordshire Regiment; W. G. Mitchell, M.A., M.D., 5th Volunteer Battalion the Gordon Highlanders; H. H. du Boulay, 1st Dorsetshire Volunteer Artillery: R. Beveridge, M.B., 3rd Volunteer Battalion Durham Light Infantry; S. Lodge, M.D., 3rd Volunteer Battalion the Prince of Wales's Own West Yorkshire Regiment; W. Murdoch, M.D., 3rd Volunteer Battalion the King's Own Scottish Borderers: James Taylor, M.D., 6th Volunteer Battalion the Gordon Highlanders; E. W. St. V. Ryan, 16th Middlesex (London Irish) Rifle Volunteers; L. E. Shore, M.A., M.D., Cambridge University Rifles.

At the distribution of prizes to the 1st Middlesex Volunteers, R.E., on Dec. 13th, a presentation of a handsome silver bowl and illuminated address was made by Field Marshal Sir John Lintorn Simmons, K.C.B., K.C.M.G., &c., the Honorary Colonel, on behalf of the officers, past and present, to Surgeon-Lieutenant-Colonel Baines, V.D., M.D., on his retirement after thirty-six years' service in the Corps.

THE ASHANTI EXPEDITION.

As far as the health of the troops and the medico-sanitary aspects of the expedition are concerned the prospects remain as satisfactory as they were. The attitude of Samory, the chief of the Mahommedan tribe, seems doubtful however, and this introduces a factor of military importance, as they are a warlike people and well armed. It is rumoured, too, that King Prempeh has arrested the only two white men in Kumasi as spies. Large quantities of stores have been landed at Cape Coast Castle and are being rapidly pushed to the front. Several British officers have made rapid marches to Prahsu to complete all the necessary arrangements and to construct the bridge over the river Prah. There is no lack of native bearers to act as transport; the chief difficulty that is to be feared in regard to them is that no dependence can be placed upon their courage, as they will probably fly in the event of any attack. No change appears to have been made in the plan of the expedition. Satisfactory assurances have been received as to the attitude of the Koranza tribe, through whose country it is proposed to make a diversion to Kumasi on the advance of the force over the Prah to the capital. The tribes inhabiting the country generally have suffered too much from their Ashanti neighbours in the past to have any love for them. Surgeon-Colonel Taylor, the principal medical officer of the force, has issued a leaflet containing a number of simple and practical suggestions for the information and guidance of the soldiers. Great progress has been made in the hospital arrangements for the force and in the formation of rest camps along the line of march, and a great deal has been effected in the way of clearing a road for the troops. The health of the expedition is reported to be satisfactory. A certain amount of sickness and fever was in any case to be expected, but it has been so far very small, and not at all of a severe character.

THE ABYSSINIAN CAMPAIGN.

The Italian War Office is sending out large reinforcements to strengthen their garrison in Abyssinia after the unfortunate reverse they lately sustained in that country. It is everywhere recognised that the officers at the late fight at Ambalagi, by their extreme bravery and devotion under most trying circumstances, reflected great credit on the Italian army. The *Italia Militare* states that after the departure for East Africa of the first nine battalions, five other battalions also sail during this month with two additional battalions of mountain artillery. A large contingent of the Medical Service, with hospital stores and equipments, will be required with this force, especially as the arrival of the Italian troops in Abyssinia will probably soon be followed by

Digitized by Google

active operations against the Shoans, who are, by the way, said to be suffering from lack of provisions.

THE COMMANDER-IN-CHIEF.

The speeches made by Viscount Wolseley at Woolwich and Sandhurst have, we think, created a very favourable impression. They are quite in keeping with the views he has always expressed in regard to the army being made to offer in the future a professional career for officers, and his desire to see the bond between them and the men under their command not one of mere discipline, but of comradeship also. We are glad to notice, too, that the Commander-in-Chief has, by his example, recently practically discouraged unnecessary extravagance at mess. This is a step in the right direction now that a larger proportion of young men of relatively small means are entering the army than was formerly the case.

THE MADAGASCAR EXPEDITION.

The health of the French force in Madagascar is said to have much improved of late. It will, of course, take some time before those who have contracted malarious fever of even a mild type can have their health fully restored, but most of those who have been seriously attacked or who have suffered from dysentery and were fit to travel have been already invalided from the country. The climate of the uplands is comparatively healthy, and now that the French troops occupy quarters in the capital, and are, we trust, fairly fed and provided for in every way, their health and strength should become far more satisfactory. The late expedition was of a most arduous kind according to all accounts.

THE INDIAN CHOLERA REGULATIONS.

A committee has been appointed by the Government of India—consisting of the Quartermaster-General, the Principal Medical Officer of Her Majesty's Forces, the Sanitary Commissioner with the Government of India, and Professor Hankin—to consider and revise the cholera regulations for India.

Correspondence.

"Audi alteram partem."

"CHELSEA HOSPITAL FOR WOMEN."

To the Editors of THE LANCET.

SIRS,—I beg to be allowed to correct an error of fact which has crept into your editorial article of Dec. 21st on the action taken by the council and governors of the Chelsea Hospital for Women in relieving a member of the honorary staff of his duties. You say "as a result of that report [of the Committee of Inquiry in 1894] the medical staff of the hospital resigned, and the lay management should have done the same." As a matter of fact, the board of the Chelsea Hospital for Women did resign at the same time as the medical staff, and the present council (the great bulk of whom are new members) was elected by the governors at a meeting held on Nov. 28th, 1894.

I am, Sirs, your obedient servant,

Dec. 23rd, 1895. GLENESK.

*** We are sorry to be compelled to correct Lord Glenesk in matters of fact in the recent history of the hospital over whose fortunes he presides. The lay management of the Chelsea Hospital for Women did not resign upon the presentation of Lord Balfour of Burleigh's condemnatory report. This report was presented in July of last year, and the medical staff immediately resigned. The lay management stuck to office and set about electing a new medical staff. A resignation of the lay management took place in the following November, but that is not "the same time," nor did this resignation depend upon the fact that severe censure had been passed upon them; at least, if it did, Lord Glenesk, who tendered it, gave a different reason.—ED. L.

To the Editors of THE LANCET.

SIRS,—From your report of the meeting it would convey to the profession that 123 governors had voted and that only 17 were for me and arbitration, whereas only 57 persons voted—40 against and 17 for me; but the majority of 40 included 22 persons who were members of the board and staff and their families, and therefore personally interested in the question they voted upon. Of the remaining 18 I am advised one was not qualified to vote, so that of the independent voters 17 were for arbitration and 17 against. Neither my wife nor I voted, although entitled to do so. The result was therefore brought about by the iniquitous system of cumulative voting in vogue at this hospital. Furthermore, many influential governors who were unable to attend either wrote or wired to the chairman demanding inquiry. These facts speak for themselves.

The question which naturally arises in the professional mind after reading the many inaccurate statements (which were after careful pruning sent to the daily papers, while the powerful common-sense speech of Mr. Burdett-Coutts, the late vice-chairman, was suppressed) is, Why did the board want me to resign? The following letter written by me to them will explain:—

June 23rd, 1895.

GENTLEMEN,—I beg to acknowledge your letter of the 20th inst., and to say that it is quite true that I have expressly forbidden your resident medical officer to interfere in any way with my operation cases. It is quite *untrue* that my staff nurse treats my patients beyond carrying out my instructions. With regard to your remarks as to rules, I know of no rule that can interfere with my responsibility in the care and treatment of my patients, and I will not share with an inexperienced resident medical officer this grave responsibility in any serious operations which I may have from time to time to undertake. Both he and my staff nurse and matron are instructed that, in case of any condition arising in which my presence is required, they should wire for me, or, if at night, send a hansom. My time is my patients', and in less than an hour I can always be at their bed-side. This is the system to which I always have been accustomed, and to which I mean to adhere. That it is no experiment is evident from the fact that in the Samaritan Hospital, which may be called the parent institution for abdominal surgery, under Sir Spencer Wells and his successors the medical staff have persistently refused to commit their cases to a house surgeon, and to this system they attribute their great success, which is a matter of common notoriety. The necessity for this arrangement has been forcibly brought before me by the treatment of my last hysterectomy by the resident medical officer.

The treatment referred to is this: Within eight hours after a hysterectomy the house surgeon tightened up the serre-nœud which was on healthy uterine tissue, removed all the dressings superficial and deep, which meant lifting up the pin and taking out the pressure pads, and interfered a second time the next morning early, all this being done without sending for me, *which he had strict orders to do.* These are facts which are undeniable; I saw all these dressings next day. For this disobedience to my wishes I reprimanded the house surgeon, and he took the very unusual course of reporting me to the board—hence my letter. I leave my action towards him and my views on this subject gladly to the criticism of any abdominal surgeon in Europe. All that I insisted upon in my so-called "reform" was that the after-treatment of these grave cases should be left to me alone. I never placed the house surgeon in an inferior position to a nurse; he had complete charge of all my other cases. This was only one of many red herrings drawn across the track while evading the main point. The board asked me to withdraw this letter, which I refused to do, as I felt conscientiously that those were the only conditions under which such terrible operations were justifiable, hence their antagonism to me. It is some satisfaction to feel that such men as Sir Spencer Wells, Mr. Jonathan Hutchinson, and Dr. Robert Barnes found coöperation with this board impossible, and that since their resignation no man of position in London could be found willing to accept the post of consultant, although many men of mature wisdom and experience have been approached to this effect. Why does this state of affairs exist? Public inquiry is the only means of solving this question. I am ready to place my case in the hands of any such tribunal, and to prove the veracity of all my statements.

Here I can only simply deny the insinuations made against me by the chairman and some of the staff. For the present I leave my reputation, and their treatment of me, cheerfully to the judgment of my professional brethren, feeling certain that as "Right is might" I will yet get an opportunity of meeting my enemies in the gate.

I have the honour to be, Sirs, your obedient servant,

Harley-street, W. ROBERT O'CALLAGHAN.

To the Editors of THE LANCET.

SIRS,—The scrutiny of the votes given at yesterday's meeting resulted as follows: for the resolution put from

Digitized by Google

the chair, 107; against, 17. (The numbers as counted yesterday were 106—17.)

I am, Sirs, yours faithfully,
HERBERT H. JENNINGS, Secretary.

Chelsea Hospital for Women, Fulham-road, London, S.W., Dec. 19th, 1895.

THE CASE OF MRS. GUTHRIE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 16th of this year an appeal appeared on behalf of Mrs. Julia Guthrie, widow of the late Professor Guthrie, formerly surgeon to the Westminster and Royal Westminster Ophthalmic Hospitals. This appeal was signed by Mr. Upton of Brighton, who stated that Mr. Brandreth, LL.D., a solicitor, would act as treasurer of any fund which might be raised. In the issue of the following week I wrote pointing out that all surgeons were deeply indebted to the author of the "Commentaries on the Surgery of the Peninsular War," especially for his work on the subject of hæmorrhage and its treatment. I expressed the hope that Mrs. Guthrie, then seventy-five, would not be allowed to die of want, and suggested that if each of a few surgeons would guarantee her a guinea or two a year the difficulty would be met. Very little resulted directly from the appeal, but I spoke and wrote to various friends, and was enabled by their kindness to transmit to Mr. Brandreth £25 12*s*. Some six months later, on sending Mr. Brandreth my second subscription, it was returned by an official receiver. Mr. Brandreth had become bankrupt, and there appears to be no hope of recovering the money which he received on behalf of Mrs. Guthrie. I have been informed that at his further examination Mr. Brandreth admitted having thus received a considerable sum, one gentleman alone having given fifty guineas. I have been further assured that Mrs. Guthrie had on Oct. 26th received only £23 from Mr. Brandreth — not even so much as had passed through my own hands. I need hardly say that this result has been a cruel disappointment to Mrs. Guthrie. Had it not been for a little timely help she would now have been not only penniless and without necessary clothes, but in debt. I believe that she is now again without money. Under these circumstances, I venture again to ask for help on Mrs. Guthrie's behalf, and to offer to acknowledge and administer any sums which may be sent to me for her. I am, Sirs, yours faithfully,

134, Harley-street, W. STANLEY BOYD.

"THE ADMISSION OF WOMEN TO THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—The letter of Mrs., Miss, or Mr. Marion Ritchie—I beg his or her pardon, for I have not the honour of his or her acquaintance—certainly does not disprove my statement of "facts," but to my mind clearly confirms their accuracy. I am not in the habit of making statements unless they are facts. How your correspondent is in a position to prove that, as stated, "no medical woman in practice in England has ever taken less than a guinea" I cannot say; still, I will not go into the question whether this is a fact or not. This fact, however, remains, that "women students," "officered by medical women," attend the poor women of Battersea and Clapham for a fee of 5*s*., and these poor women believe not only that they are paying "a doctor's fee," but the majority of them believe that they are going to have a doctor to attend them for this fee. Instead of this they find out, often to their regret afterwards, that they are being practised upon and that they are paying for the privilege into the bargain.

It would be interesting if your correspondent would inform the treasurer of the Hospital Saturday Fund whether they are receiving any of that Fund, and also that they are charging the extreme poor of such a poor parish as Battersea a fee of 5*s*., or as much as they could, to secure the services of a skilled midwife to replace the unskilled attendance of beginners. It is immaterial to the poor woman whether the fee of 5*s*. is paid "to the funds of the hospital" or goes into the pocket of anyone else. The fact remains that medical women, no matter whether qualified or not, are attending cases of midwifery for a fee of 5s., at least in Battersea, and I am informed that some of our poorer brethren, in order to deal with this disgraceful competition of women, are accepting fees which are almost as low in order to keep the wolf from the door. I sincerely trust that some of them will enlighten us upon the subject. I know of at least one case where an unmarried woman who was pregnant and had engaged a medical man to attend her for a fee of £1 1*s*., but was attended at one of these so-called hospitals conducted by women. It is this disgraceful competition of so-called hospitals, and their congeners that is helping so largely, not only to pauperise the people, but also to impoverish that noble profession to which we have the honour to belong. I am, Sirs, yours truly,

Weymouth-street, W., Dec. 13th, 1895. A. MORTON.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me space to give a point-blank contradiction to the assertion made in a letter signed "Vigilans" in your issue of Dec. 21st, that the Clapham Maternity was originally started as a "private speculation" by a medical woman? It originated in the work of a medical mission opened in Clapham in 1885 by the Church of England Women's Missionary Association, with the coöperation of several well-known London and Clapham medical men. The post of medical officer for this work was advertised in THE LANCET, and by that means obtained by the lady named by your correspondent, but she was a total stranger to the originators and had no pecuniary interest (beyond her fixed salary) in their arrangements.

I am, Sirs, yours truly,
MARION RITCHIE,
Hon. Sec., Clapham Maternity.

*** This correspondence must now cease.—ED. L.

"THE CASE OF DR. WIGHT."

To the Editors of THE LANCET.

SIRS,—I am glad that your correspondent "M.D." has called attention to the omission by the defence in the above case to call evidence to show that rupture of the uterus may occur in labour irrespectively of all operative interference or during the most careful and skilful manipulations. I can instance a case in point. About three years ago I was called in to attend a primipara forty years of age. The messenger stated that she was in severe continuous pain, and her mother was afraid she was dying. On arrival I found I had to do with a dying woman, apparently suffering from internal hæmorrhage. I injected ether hypodermically and made an examination per vaginam, but could not detect any dilatation of the os. She died in a few minutes. I offered to do Cæsarean section to try to save the child, but the husband would not consent. At the necropsy I found an extensive rupture of the uterus, the walls of which were so thin that they did not appear much thicker than the membranes; in fact, the whole of the nutrition of the uterus seemed to have been expended upon a very large fibroid which involved a large portion of the lower part of the uterus. Had this rupture taken place during a later stage of the case or when forceps were being applied I am afraid it would have been, to say the least of it, unpleasant for me.

I am, Sirs, yours faithfully,

Dec. 11th, 1895. ANOTHER M.D.

THE SOIL IN RELATION TO DISEASE.

To the Editors of THE LANCET.

SIRS,—In your issue of Dec. 14th I have read with the greatest interest Dr. Poore's lecture on the Soil in its Relation to Disease and Sanitation. In common with most officers of the Indian Medical Service I can bear witness to the value of human excrement as manure. In the Bengal gaols, and I believe in most others in India, the whole of the fæcal excrement is trenched in the gaol garden; and these gardens generally yield excellent crops. There is never any unpleasant smell except for a brief period during the "rainy season." Even then the smell is not very noticeable and can be overcome if the trenches are made a little deeper than is necessary at other times of the year. As in the case of Dr. Poore's garden the fæces, covered with earth, are generally merely buried and the "humification" left to nature. This process, however, may be hastened by an excellent scheme which is

Digitized by Google

in use in the Presidency Gaol, Calcutta. The superintendent, Mr. P. Donaldson, by an ingenious use of the Archimedean screw, devised a machine in which the fæces and earth are most intimately mixed. This mixture is ground out through a hole in the gaol wall and is received into pans. It is carried at once to the garden. I was for some time medical officer to the Presidency Gaol, and I can say without hesitation that I never noticed the least smell in or around the garden. Dr. Poore's well is also very interesting to me, since it carries out and improves upon a principle on which, in my sanitary reports as a civil surgeon, I have always insisted with regard to shallow wells.

I am, Sirs, yours faithfully,

J. H. TULL WALSH,
Surgeon-Captain I.M.S.

Roughton, Dec. 18th, 1895.

THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—On reading in your columns the remarks of Sir Richard Quain as to the disabilities of the legal profession, I could not see that there was any reason for our being content with the present constitution of our Council. Some of us from Lancashire and Cheshire, who were present at its session in May last, certainly were not favourably impressed with what we witnessed. Had we been shareholders in an undertaking having in its employment or government 32,000 hands, we should not have felt satisfied in leaving it in the hands and under the control of such a body of men, neither should we have felt content that even the affairs of a city would be effectually managed with a similar body of men in its Council. We certainly do hope that those members of our profession who can visit the council chamber during the session will avail themselves of the opportunity, for the public have free access, as they will then see how and by whom the business of the government of the profession in these realms is conducted. Surely there ought to be some limit as to the age when elected. At our Manchester Royal Infirmary the limit for holding appointments is sixty. Is there any reason why some such restriction should not be adopted in our governing body? Surely hundreds of capable and reliable men can be found in the country under that age who have the necessary energy and ability which would command the respect and confidence of every man. As to Sir Richard Quain's remarks about the direct representatives, many of us in this part of the country are of opinion that, if we had had more, we should have had a far more practical outcome of the investigations in reference to medical aid associations than we can find in their report on that question.

One effectual means of bringing the medical officers of such trading institutions into line would be to have an annual registration, as in the legal profession that the president referred to. If the amount of the fee were 5*s.*, the Council would have an additional income of about £8000. This would provide us with ten additional direct representatives, and leave a large balance to be applied to some other useful purpose for the benefit of the profession at large.

It is not necessary to dwell at length on the advantages that would be derived from an annual registration; but this one might be stated, that such men as I have mentioned would at once begin seriously to reflect that it would be absolutely necessary to put their houses in order. For the first year or two there might have to be a prolonged session of the Council or its executive to inquire into the reasons why certain men should not be again licensed to practise, or whether their licences should be endorsed, both as a record and a warning, as is done by the magistrates in certain other licences. But as time went on and better discipline resulted, the extra sessions would become small matters, for members would always feel that they were under the direct control and supervision of the General Medical Council.

I am, Sirs, yours faithfully,

G. H. BROADBENT.

Manchester, Dec. 7th, 1895.

PRESENTATION.—Mr. J. Griffiths Whittindale, L.R.C.P., L.R.C.S., district medical officer, Old Calabar, Niger Coast Protectorate, has been presented by the European, residents as a token of the high esteem in which he is held by them, with a handsome silver-mounted dressing-bag for his wife and a canteen of plate and silver-mounted cigar-box for himself.

THE BATTLE OF THE CLUBS.—XV.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1541.)

NORTHAMPTON: THE FRIENDLY SOCIETIES AND THE NATIONAL MEDICAL AID COMPANY, LIMITED.

AT Northampton, next in importance after the Royal Victoria Dispensary, is the Friendly Societies' Medical Institute. The total membership of this important organisation amounted, in 1894, to 13,154. The income for that year was £1737 2*s.* 6*d.*, and the expenditure £1667 4*s.* 6*d.*, leaving a surplus of £69 18*s.* Out of this expenditure £660 16*s.* 8*d.* were paid to the medical officers of the institute, and as, during the course of the year, they gave 44,192 consultations the medical officers were paid at the average rate of a little over 3½*d.* per consultation. One of the former medical officers of this institution states that no medical man could manage the work for this and similar institutions unless he is prepared to see from thirty to forty patients per hour at the surgery and to visit from ten to fourteen patients at their own homes also in the course of a single hour. The committee, however, have now resolved to establish some sort of limit to the number of patients to be seen by the officers. They have determined under no circumstance to pay their head medical officer more than £300 a year. If the number of members increase they will not augment this salary, but will appoint another assistant medical officer. Actually, there are two assistant medical officers. Some time ago the chief medical officer of this institution resigned because, among other reasons, he objected to the interference in medical affairs of an absolutely incompetent lay committee. At that time the committee consisted of three paper-hangers, three compositors, two barbers, two shoemakers, two porters, one baker, one miller, two clerks, one grocer's assistant, and one ex-policeman. This committee holds in its hands the very conscience of its medical servants. The committee meet and pass resolutions governing the medical service without so much as consulting the medical officers. When the chief medical officer on one occasion protested, the president of the managing committee replied: "You must do what we say while you *was* in our service." It stands to reason that these medical servants of uneducated lay committees cannot afford to give due consideration to the welfare of the patients. They are not allowed the time necessary to properly examine the patients, neither have they the leisure to read current medical literature and keep themselves posted in the progress of medical science. They must go on prescribing at express speed and by rule of thumb, and the committees of management are too ignorant to understand how this degrades the profession and endangers the health of their members. As for a wage limit, there is none. One of the mayors of Northampton and all his family belonged to, and obtained medical aid from, the Friendly Societies' Medical Institute. A member of this institute did not scruple to seek its medical aid, though he was able to pay £21 to a surgeon for a special operation performed upon his wife. A retired publican used to pay guinea fees to a consulting physician, though for ordinary complaints he obtained his medicine from the institute. A Poor-law guardian was also a member of this institute; and men who are too highly placed to join this friendly society for its general benefits send some of their sons to be enrolled as juvenile members. According to the rules, the family of a member can join the friendly society, not necessarily for all benefits, but for the medical aid only. Thus a comparatively rich man, who does not want to subscribe for a sick allowance or a funeral fund, enters his son as a member for these benefits; and then, on the strength of this relationship, brings in all the family for the medical aid of the Friendly Societies' Medical Institute. Thus the middle-class element that no longer cares for the ordinary financial benefits given by these friendly societies manages to come in all the same for the medical aid. Yet these are the very people who

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Aug. 24th, 1895, Brussels; (2) Aug. 31st, 1895, Brussels; (3) Sept. 21st, 1895, Portsmouth; (4) Sept. 28th, 1895, Portsmouth; (5) Oct. 5th, 1895, Eastbourne; (6) Oct. 12th, 1895, Lincoln; (7) Oct. 26th, 1895, Lincoln; (8) Nov. 2nd, 1895, Grimsby; (9) Nov. 9th, 1895, Bexhill-on-Sea; (10) Nov. 16th, 1895, Hull; (11) Nov. 23rd, 1895, Hull; (12) Dec. 7th, 1895, York; (13) Dec. 14th, 1895, Northampton; (14) Dec. 21st, 1895, Fermanagh Medico-Ethical Association.

Digitized by Google

could well afford to pay medical men proper fees. Then, to further swell their incomes, the friendly societies take in women and children, and these require so much attendance that they overwork the medical officers, who are therefore not able to give proper attention to adult male members. Yet, in their origin, such institutions were specially intended to help the breadwinners. This is a serious commercial injury to the community, as it tends to reduce not only the income of the families but the output of goods manufactured. It must also act injuriously to such friendly societies as allow a higher sick pay to their adult male members.

Northampton has a population of about 64,000 inhabitants, and more than half this population are medically treated at the two great dispensaries—the Royal Victoria Dispensary and the Friendly Societies' Medical Institute. But this is not all. There are many small clubs which have no dispensaries of their own and contract with some local practitioner for medical attendance; and then we have in full force the National Medical Aid Company, Limited, acting on behalf of the Liverpool Victoria Legal Friendly Society and offering to anyone and everyone medical aid if they will only insure their lives. This medical aid company employs five practitioners in the town, and one of these practitioners assured me that he had had as many as from 3000 to 4000 subscribers to this company on his books. Thus, if we add the probable number of members of the small clubs and of the National Medical Aid Company to the members of the two great dispensaries already described, and further take into consideration those who are treated at the hospital or infirmary and those who come under the Poor-law, we shall be puzzled to find what population remains for the private practitioner. It may safely be said that three-quarters of the population receive medical aid and are withdrawn from the reach of the private practitioner. In the event of an epidemic there is a little more hope; for the club and dispensary medical officers cannot do all their work, and some of the members, finding that they are kept waiting too long or are treated too hurriedly, call in a private practitioner. Strange to say, these casual patients usually have no difficulty in paying proper fees, and this again tends to show that there is no efficacious wage limit. Indeed, can it be maintained for a moment that three-quarters of the population of Northampton are incapable of paying medical fees? Yet this is what those who would urge there is no abuse must prove. As a matter of fact, of course, everybody recognises that there are numerous abuses, but the tendency is to blame other societies than the one to which they each individually belong. So far as the medical profession is concerned, the action of the National Medical Aid Company constitutes the worst grievance. Nowhere have I heard such a chorus of complaints as at Northampton, and in these complaints there was a new feature. It seems that this company not only employs its medical officers to compete against all other medical men, but actually sets its own paid officials to fight against each other. As soon as one of its medical officers becomes a little popular, or when there is some fear lest he should be able to create for himself a private practice, or if perchance he should offend the company's local superintendent, another medical man is brought down from some distant town and a number of the patients transferred to the new-comer. I was able to talk this matter over with two practitioners who had been introduced into the town in this manner. The first explained that he had only recently obtained his diploma when he was approached by the National Medical Aid Company. He had no experience and no knowledge of the workings of this society, but was very pleased at the prospect offered him of an assured, if small, income. He therefore consented to be their medical officer. The very next day a number of patients came to his surgery, and he was not a little concerned to find that many of them suffered from chronic diseases. On asking them some questions he discovered that they were all patients of another practitioner who lived in the neighbourhood and whom he knew to be also in the employ of the National Medical Aid Company. These patients had been told by the collectors or canvassers in the employ of the company not to go any more to the medical man they had been accustomed to consult, but to go to the new officer whose services the company had just secured. This was very disconcerting intelligence, for he did not care to take another practitioner's patients, and thus actively side with a lay, speculating, financial company in its quarrel with one of his colleagues and fellow medical men. Then, on making further inquiries, he ascertained that the company was employing twelve or thirteen canvassers, who went to almost every house in Northampton seeking to persuade the inmates that the medical men of the National Medical Aid Company were far and away the best, adding to these assertions wonderful descriptions of cures supposed to have been effected by the company's medical officers. These canvassers, who were thus trampling underfoot all principles of medical etiquette, made good incomes out of the life insurances with the Liverpool Victoria Legal Friendly Society which each subscriber to the National Medical Aid Company is compelled to effect. As a commission the canvassers obtain the whole of the premium paid for a life insurance during the first sixteen weeks. After that, as they continue to collect the money, they receive 25 per cent. of what they collect. When once a connexion is established the collector can sell his book to another collector who wishes to come into the business. For instance, a £5 book means an income of £1 5s. weekly, and the goodwill is worth something. Now these canvassers have the making or destroying of a medical man's reputation. They bring the patients, and they can take them away again. For the most part the people enrolled by these canvassers are of a very low and troublesome class. Many do not join of their own free will, but are worried into consenting by the reiterated calls and the irrepressible volubility of the canvasser. On the other hand, when once they have been induced, in spite of themselves, to pay a few weekly subscriptions, they begin to think it is time they should get something for their money. Consequently they march off to the medical officer, make up some sort of story, waste his time, but get a bottle of physic, and go away satisfied because they have obtained something for their money. In view of all these circumstances, the practitioner on whom I had called explained that he very soon severed his connexion with the National Medical Aid Company, and expressed his utter disgust with its methods and proceedings.

The company next employed a medical man who became very popular, and who died when his practice was worth a good £400 per annum. The company, however, refused to transfer its members to the possible purchaser of this practice and brought in a medical man of its own, a stranger to the town. Thus, when a medical man has, after years of arduous and poorly paid labour, built up a practice, this in case of death may not be sold; his family cannot inherit the proceeds of such a sale, because a lay company chooses to withdraw its members, though the skill and devotion the medical man had shown in a great measure enabled the company to obtain these members. The importance of this practice, which the National Medical Aid Company would not allow to be sold, is shown by the fact that the practitioner it introduced to take the place of the defunct medical officer soon had upwards of 3000 members on his books. Now, however, he has scarcely 1000, and the reason of this falling off is most edifying. The new medical officer elected to live in a fashionable part of the town. This district was healthier, more pleasant, and there was some chance of creating a private practice. The company, on the contrary, wanted to take him to the popular and overcrowded side of the town. There he would have had such a crowd of the company's patients that he would not have found either time or opportunity to cultivate a private practice, and would, therefore, have been absolutely dependent on the company, and obliged to obey its every beck and call. Indeed, this is so thoroughly its object, that by a combination of persuasion and menaces it often succeeds in inveigling medical men to sign agreements by which they became practically the slaves of the company. But the new medical officer would not sign any such agreement, and he could not be persuaded to live in one of the slums of the town. Further, he began to make various discoveries which did not please the canvassers. For instance, the subscription for medical aid is 2½*d.* per week per family, but the canvassers accepted 10*d.* a month, and the year consists not of forty-eight but of fifty-two weeks. The new medical officer complained. The company did not like all this, and, therefore, yet another medical officer has been brought by the company into Northampton, and this accounts for the sudden and considerable falling off of members on the books of the medical officer who ventured to complain. The fact is that the canvassers do not care how little is paid for medical aid;

Digitized by Google

their interest is in the premium for life insurance. The medical officer counts on receiving 10*s.* 10*d.* per annum per family, but he only receives 10*s.* when the payment is effected per month. Then during the great strike in the boot and shoe trade very few families paid any subscriptions whatever. After the strike was over, instead of claiming the arrears, some among them were simply put on to the books of another medical officer as if they were new members—indeed, this is a common method of transferring members from one officer to another. The canvasser, instead of urging the member to pay up the arrears of subscriptions into which he has, perhaps, been purposely allowed to fall, urges him to join as a new member on some other medical officer's list. Thus are the members transferred from the medical man who is too independent to please the company to some new medical officer it has imported on purpose to compete against the more recalcitrant officer. This has the further advantage of engendering a certain amount of bitterness and rivalry between the medical officers. By dividing the company is better able to govern, and it also renders it less probable that the medical officers will be able to meet on friendly terms and trust each other sufficiently to agree on some concerted action. Then, also, by changing the collectors the accounts can be thrown into confusion, and the medical officer who has fallen into disfavour with the company finds that this confusion results in his losing a great many of the members on whose annual subscriptions he relied for his income. The medical officers in the employ of the company are for the most part in a very dependent position, and everything is done to keep them in this condition. As one of them exclaimed to me in angry protestation, "How can you call on a poor young practitioner like myself to resign? I have a wife and growing family to maintain. I have no wealthy patients and hardly any private practice. Why should I resign when medical men in this town who have large and lucrative private practices gladly work for the Royal Victoria Dispensary. Besides, if I did resign, someone else would quickly come and take my place." Of course, I protested that no good could be done by the resignation of a practitioner here or there; it was only by concerted action that some result could be obtained. The medical officer who considered it unfair to expect him to resign said, on the other hand, that he would be delighted if a decree could be issued declaring that all medical men who continued in such service would lose their diplomas. Then every medical officer would have to resign; the company and all the abuses it had introduced would disappear, but the patients would remain, and he would have his chance, equally with the other practitioners, of securing some of them.

Northampton, December, 1895.

ARE HOSPITALS TO BECOME MEDICAL CLUBS?

The medical staff of the Swansea Hospital have forced this question on the attention of the committee of the hospital. They have presented a report to the committee showing that the medical profession gives its services gratuitously to hospitals on the understanding that they are charitable institutions for the sick poor, but that little by little the readiness of medical men to coöperate with the general public in a grand scheme of kindly charity is being misused, to the detriment alike of the general body of supporters of the hospital and of the welfare of the medical profession itself. They especially show that workmen, to their great credit, make important contributions to the hospital, but that there is a growing disposition on the part of workmen and their masters to regard such contributions as giving them a right to attendance, not as a charity, but as a privilege purchased by their contributions. This is an admirably plain statement of a new theory and view of hospitals which cannot for a moment be permitted, and which is at the root of the enormous abuse of these institutions. The theory of voluntary hospitals is that they are institutions for the working classes when overtaken with serious accident or exceptional illness. Everybody is delighted to support hospitals on such a theory, and the working man should cheerfully join in supporting them in this theory. But whoever till now thought of regarding his subscription as meant to cover attendance for ordinary illness? Such a view is absurd, and if pressed will stop subscriptions and kill the hospitals. Such views are an outcome of the abuse of the out-patient department, which is now more like a market than a consulting-room, and which entices by its facilities all classes. But it is not the out-patient department alone which is abused. We gave an instance in THE LANCET of Dec. 14th of a case of cataract dealt with in a hospital where the patient was quite able to pay a fee. Here is another at Swansea Hospital. A well-to-do lady patient came in for an operation, but took fright on the death of a patient in a neighbouring bed, and left it. Outside the hospital, and as a private patient, she had the operation done and paid £20 for it, "with best thanks," paying besides for nurse and maintenance. Colonel Morgan talked on this subject with less reason, let us hope, than he would talk on military matters. He said "in his opinion working men had a right to their admission, and the benefits need not necessarily be a charity." Where can right come in when, as everybody knows, the hospital was for serious cases that cannot be accommodated at home or paid for without strain by a working man? As the chairman said, "There are the rules; we cannot alter them. The hospital is not A CLUB, it is A CHARITY." An amendment was passed particularly requesting subscribers to investigate the circumstances of the cases they recommend. Working men are not by nature shabby or incapable of subscribing for the benefit of others. They will do well not to be led by Colonel Morgan save in military matters. Of one thing they may be sure, that if they try to convert hospitals into clubs the medical staffs will refuse to act and the public will refuse to subscribe. The staff of the Swansea Hospital have distinguished themselves by an honest and firm protest which is much needed everywhere.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Glasgow Medico-Chirurgical Society.

AT a meeting of this society on the 6th inst. the following communications were submitted. Dr. Finlayson reported a case of Rupture of the Descending Aorta the result of violence, the patient having for some time after the injury continued at heavy manual labour and made little or no complaint. Dr. Finlayson also narrated a case of Aneurysm of the Arch of the Aorta, in which there had been a diastolic murmur, though the aortic valves when tested on post-mortem examination appeared competent. Dr. Dalziel showed a specimen of a Perforating Ulcer of the Duodenum which he had removed by operation after rupture into the peritoneum had occurred. The patient, who was a young woman, had made a good and uninterrupted recovery. Dr. Dalziel also showed a patient on whom he had performed a Partial Amputation of the Foot for a Perforating Ulcer of the Sole the result of injury to nerve trunks. Microscopic specimens illustrating the Histological Changes in the Nerves in Diabetic and Traumatic Peripheral Neuritis were exhibited by Dr. John Love.

Dec. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Ulster Eye, Ear, and Throat Hospital.

I FIND from the report presented at the annual meeting of this hospital held on Dec. 12th that there were 1549 patients during the year, and of these 178 were intern. The plans for the extension of the hospital have been prepared. New closets and bath-rooms, day-rooms, a laundry, better accommodation for nurses and servants, several small wards, and a new operating-room will be provided. The special feature of the addition will be the new operating-room. The floors and walls will be all tiled and cemented, so that no dust, dirt, or germs can have a hiding place, and everything will be managed in accordance with the most recent requirements of aseptic surgery. The committee have in hand available for this extension between £1400 and £1500. There have been received £71 14*s.* 6*d.* from subscriptions, £109 6*s.* 3*d.* interest on endowments, and £473 7*s.* from patients during the year. The results in operations for cataract have been very good, for in the year to which the report relates, and the part of the present year which has elapsed, there have been sixty cataract operations (exclusive of those caused by injury), with a result of more than 98 per cent. restored to vision. The year commenced with a balance against the

Digitized by Google

institution of £253 11*s.* 3*d.*, and closed with a balance against it of £151 10*s.* 2*d.* It is hoped that during the present year the financial condition will show an improvement.

Dec. 23rd.

Obituary.

THOMAS EDWARD AMYOT, F.R.C.S. ENG.

THE announcement of the death of Mr. Amyot, of Diss, Norfolk, has been received with deep regret by a large circle of patients and friends, hardly any medical man being more widely known and esteemed throughout the county than he was. His connexion with Norfolk was long established; his mother was a daughter of Mr. Colman, a surgeon in Norwich, and he has practised his profession in Diss since 1846—a period of nearly fifty years. His father was Thomas Amyot, F.R.S., a distinguished man of letters and a prominent member of the Society of Antiquaries and the Shakespeare, Percy, and Camden Societies. Mr. T. E. Amyot was born in London in 1817, studied medicine at St. Bartholomew's Hospital, gained the diploma of Membership of the Royal College of Surgeons of England and the Licence of the Society of Apothecaries in 1839, and in 1866 he became a Fellow of the Royal College of Surgeons. Mr. Amyot was a man of great mental activity, which displayed itself in many and diversified ways. A careful and judicious practitioner, and one who zealously kept up with the great advances in medical knowledge which have been made during his long career, he delighted in literature and music and devoted much of his leisure to the microscope and to the study of astronomy, geology, and botany. Among his contributions to periodical medical literature was an account of an occurrence of foot-and-mouth disease in the human subject. He was a member of the Norfolk and Norwich Medico-Chirurgical Society and had filled the office of president both of that society and of the East Anglian Branch of the British Medical Association. For some time Mr. Amyot had shown symptoms of infirmity incidental to his advanced age, and the end came with the utmost peacefulness on Dec. 15th. The funeral took place in Diss cemetery on Dec. 19th in the presence of a large assemblage of sorrowing friends. Mr. Amyot has been a widower for some years, but has left a son and a daughter.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BUNCOMBE, W. D., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Superintendent to the Infirmary, City of London Union.

CAMERON, R. D., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Wallingfen Sanitary District of the Howden Union.

CARRÉ, GERARD, M.D. Brux., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon (non-resident) to the Royal Ear Hospital, Soho-square.

CHRICTON, H., M.B., B.S. Durh., has been appointed Resident House Surgeon to the Ingham Infirmary, South Shields.

CHETWOOD-AIKIN, K. C., M.B. Aberd., has been appointed House Surgeon to the Central London Ophthalmic Hospital.

COOKE, W. H., M.D. Brux., M.R.C.S., L.R.C.P., L.S.A., has been appointed Resident Medical Officer to the Royal United Hospital, Bath.

CROSS, E. J., L.R.C.P. Lond., M.R.C.S., D.P.H. Camb., has been appointed Medical Officer for the Second Sanitary District of the St. Neots Union.

DEWAR, T. F., M.D. Aberd., C.M., B.Sc. (Pub. Health) Edin., has been appointed Medical Officer for the Burgh of Monifieth, N.B., vice Templeman, resigned.

ELLIOTT, THOS., M.D. Dubl., L.M., L.R.C.S. Irel., has been appointed Medical Officer for the No. 1 Sanitary District of the Tonbridge Union, vice E. J. Penney, resigned.

HAWORTH, J. J., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Filey Sanitary District of the Scarborough Union.

HUNTON, FRED., M.D., B.S. Durh., has been appointed Medical Officer for the Stockton Sanitary District and the Workhouse of the Stockton Union.

JONES, JAS. H., M.B., M.S. Edin., has been appointed Medical Officer of Health for the Newport (Mon.) Port Sanitary Authority.

MARTINE, W. R., M.B., M.S. Edin., has been appointed Medical Officer to the Haddington Oddfellows' Society.

MILLER, WALTER F., M.B. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Alwinton Sanitary District of the Rothbury Union, vice J. H. Hart.

OLIVER, WILLIAM, M.B., M.S. Edin., has been appointed District Medical Officer for the Saddleworth Union.

PEPPER, H. M., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Resident Assistant Medical Officer to the Royal Berkshire Hospital, Reading.

SMITH, REGINALD, M.R.C.S., L.R.C.P., has been appointed House Surgeon to the West Norfolk and Lynn Hospital, King's Lynn, vice C. E. M. Lewis.

SOMERVILLE, T. A., L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Medical Officer of Health by the Winslow Urban District Council.

SPRENT, W. S., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Surgeon to the Royal Hovingham Lodge of Oddfellows, vice T. M. Watt, resigned.

STURGES-JONES, W. E., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Peruvian Corporation in the Colony of the Perené in the Republic of Peru.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRIGHTON AND HOVE LYING-IN INSTITUTION AND HOSPITAL FOR WOMEN, West-street, Brighton.—House Surgeon, unmarried. Salary £80 per annum, with furnished quarters and board, gas, coals, and attendance.

CITY OF LONDON UNION INFIRMARY.—Dispenser at the Infirmary, Bow-road, E. Salary £100 per annum and dinner daily. Applications to the Clerk to the Guardians, 61, Bartholomew Close, E.C.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the current half-year is given in this week's issue, which completes the second volume of the year 1895. The practice of supplying loose copies of the Index was discontinued at the end of last year. The Index is now placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1895 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half-year's numbers will also be ready in a few days. Cloth, gilt lettered, price 2*s*.

To be obtained on application to the Manager, accompanied by remittance.

TO CORRESPONDENTS.

THE pressure of matter in the present number of THE LANCET has been such as to necessitate our deferring the answers to several interesting questions by correspondents till next week.

THE LIONEL SMITH FUND.

WE have pleasure in announcing the receipt of the following subscriptions in answer to our appeal, and beg to earnestly recommend the case to the attention of our readers for reasons which we have set out in our last issue (p. 1592):

The Proprietors of THE LANCET	£10	10	0	Per Dr. S. S. Sprigge	£4	4	0
Dr. Schorstein	1	1	0	Mr. J. G. Macoskie	0	5	0
A. R.	1	1	0	R. D. B.	0	10	6
Dr. Fredk. W. Saunders	0	10	0	Dr. Wm. R. Huggard	2	2	0
Dr. T. Kilner Clarke	2	2	0	Dr. A. G. Miller	0	10	0
H. M.	5	0	0	Dr. Claude Wilson	1	0	0
Dr. Clement Dukes	1	1	0	K. W. M.	0	10	6
Dr. J. Connel	1	0	0	A Brother Medical Freemason	3	3	0
Mr. B. B. Broadbent	2	2	0	Dr. H. P. Cholmeley	1	1	0
Dr. S. S. Sprigge	1	1	0				

Subscriptions will be received at THE LANCET Offices and acknowledged in our columns. Communications on the subject should be marked "Lionel Smith Fund."

Secundus.—The L.S.A. being, if obtained since 1886, a qualification in medicine, surgery, and midwifery, is admitted as a complete qualification for Poor-law purposes, and thus stands on an equal footing with the qualifications conferred by the Conjoint Board of Physicians and Surgeons in London.

Anxious.—Yes.

SMOKING FOR STAMMERERS.

To the Editors of THE LANCET.

SIRS,—Might I ask what the effect of smoking is on the stammerer? I read in one of Lytton's works that stammering lips should put a pipe between them by way of improving respiratory power, and possibly for the effect of the sedative on the coördination of the vocal apparatus. I have tried the weed in these cases, but the result is far from satisfactory, and in those in whom the nicotine dries the mouth very much I should think the result must be very bad. Can anyone throw any light upon this point?

I am, Sirs, yours faithfully,

Aston-on-Clun, Salop, Dec. 20th, 1895. H. CUTHBERT.

A HARD CASE.

C. J. wishes to know if there is any home where a patient aged eleven, partially crippled from infantile paralysis, can be received without payment. Patient is a hermaphrodite, but decidedly on the male side. Patient has been hitherto treated as a female, but a change in this respect is desirable.

M.O.H.—The data given hardly suffice for a definite opinion; but we may inform our correspondent that there is a good deal of roseola about, some of which is deemed to be of a rather hybrid type.

"THE EMPLOYMENT OF UNQUALIFIED ASSISTANTS, ETC., AND THE RESOLUTIONS OF THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—I read to-day with much interest the able letter of your correspondent, Dr. R. Hill Shaw, in THE LANCET of Dec. 14th on the above subject, and I beg to express my full endorsement of it. The matter is one which I too have often considered, and wondered why the General Medical Council permits, or does not more fully look into it. The amount of abuses which the employment of unqualified assistants in the conducting of practices entails is, I believe, an acknowledged fact on all sides, and is worthy the serious attention of the Council. The latter no doubt have passed resolutions bearing on the point which are practically useless, since the "misconduct in question" is not defined, and, besides, the punishment attached to most of them is not of a very deterring character. These omissions I understand from the tenour of your correspondent's communication to be the grievances he wishes the attention of your readers drawn to. I consider his complaint quite justifiable, in which also I take it you coincide, as expressed on page 1468 in THE LANCET of Dec. 7th last, and where you say "that the penal and disciplinary powers of the Council are still undeveloped and undecided." Such a condition of affairs ought not to exist, and I would therefore appeal to you to support the exposure of this evil, which has no benefiting effect upon the profession. The necessity for the Council to declare itself may be inferred from the numerous instances of questionable doings which the writer gives and which I could augment if I would. To do so is needless, as the mischief is too well known to everybody connected with the profession to require confirmation.

I am, Sirs, yours faithfully,

Brighton, Dec. 14th, 1895. PRO BONO PUBLICO.

"THE CLIMATE OF THE EAST COAST OF AFRICA."

To the Editors of THE LANCET.

SIRS,—As I have visited all the places mentioned by "Voyager" in his letter, perhaps the following few remarks may be of use to him. One month in which he proposes travelling—viz., March—is one of the worst on the east coast of Africa. The weather is extremely hot, the humidity great, and malarial fevers are rife. Delagoa Bay and Beira are exceptionally unhealthy places, intermittent fever or "shakes" being very prevalent at the former. Zanzibar is less so, but the fevers acquired there are, as a rule, more serious, being of the remittent type. Still, although the voyage is unpleasant on account of the damp heat, it may be undertaken with safety by healthy persons, provided moderate care be exercised and attention paid to the ordinary rules of hygiene. Sleeping on shore and on deck in harbour should be especially avoided. But for anyone in a delicate state, if the voyage be intended for health purposes, I would recommend that another direction be taken—for instance, round the Cape to St. Helena.

I am, Sirs, yours truly,

GEORGE T. BROATCH, Surgeon R.N.

Royal Naval Hospital, Great Yarmouth, Dec. 18th, 1895.

TREATMENT OF GONORRHŒA.

To the Editors of THE LANCET.

SIRS,—As I have been greatly puzzled over a case of acute gonorrhœa presenting the usual symptoms, but not at all giving way to the ordinary treatment, I trust some of your readers will give me the benefit of their more mature experience, and through your columns let me know what treatment to follow. The patient has had warm hip-baths, copaiba, cubebs, santal midy, saline, antimonial mixtures, injections of cocaine, and 2-per-cent. solution of ichthyol, but to no avail. The discharge still continues; and now to the train of symptoms are added rheumatism with occasional attacks of hæmaturia. No albumin.

I remain, Sirs, yours faithfully,

Port of Spain, Trinidad, B.W.I., Dec. 12th, 1895. ANXIOUS ONE.

"STRYCHNIA IN SNAKE-BITE."

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent "Zambaan" (THE LANCET Dec. 14th, p. 1614), I can say that arseniate of strychnine is soluble to the extent of at least 4 parts in 1000 of solution, and probably to an even greater degree. I very frequently use the solution of the strength 4 parts in 1000, and find that it is absorbed at once. I do not know what amount of strychnine is given in cases of snake-bite; a patient of mine suffering from the effects of alcoholism had 12 mgm. (= ¼ grain) in one day without experiencing any bad symptom.

I am, Sirs, yours respectfully,

A. E. CORDES, M.R.C.P. Lond.

Rue Bellot, Geneva, Dec. 19th, 1895.

ON the TREATMENT of PULMONARY CONSUMPTION. A Practical Manual. By VINCENT D. HARRIS, M.D. Lond., F.R.C.P., Physician to the City of London Hospital for Diseases of the Chest; and E. CLIFFORD BEALE, M.A., M.B. Cantab., F.R.C.P., Physician to the City of London Hospital for Diseases of the Chest. Crown 8vo, 10s. 6d. [*Lewis's Practical Series.*
THE ASEPTIC TREATMENT of WOUNDS. By Dr. C. SCHIMMELBUSCH, Privat-docent and Assistant Surgeon in Professor von Bergmann's University Clinic at Berlin. Translated by A. T. RAKE, M.B., B.S. Lond., F.R.C.S. Eng., Registrar and Pathologist to the East London Hospital for Children. With Illustrations, cr. 8vo, 5s.
A MANUAL of GYNÆCOLOGICAL PRACTICE. For Students and Practitioners. By Dr. A. DÜHRSSEN, Privat-docent in Midwifery and Gynæcology in the University of Berlin. Translated from the Fourth German Edition, and Edited by J. W. TAYLOR, F.R.C.S.; and F. EDGE, M.D., M.R.C.P., F.R.C.S. With 120 Illustrations, crown 8vo, 6s.
London: H. K. Lewis, 136, Gower-street, W.C.

IN PREPARATION.

THE REPORT of THE LANCET COMMISSION APPOINTED to INVESTIGATE the SUBJECT of the ADMINISTRATION of CHLOROFORM and OTHER ANÆSTHETICS from a CLINICAL STANDPOINT, together with the REPORT of the SECOND HYDERABAD CHLOROFORM COMMISSION. Reprinted from THE LANCET. Comprising a valuable record of Cases and Experiments (illustrated) such as, it is believed, is not to be found in the pages of any other single work.
THE LANCET Offices, 423, Strand, W.C., and 1 & 2, Bedford-street (adjoining).

DISEASES and INJURIES of the EAR. By Sir WM. B. DALBY, F.R.C.S., M.B. Cantab., Consulting Aural Surgeon to St. George's Hospital. Fourth Edition, 10s. 6d.
"All that is found in the book is sound and will stand the test of pathological reasoning and general medical knowledge."—THE LANCET.
"Few manuals on special subjects are so well written as this. No earnest student should ever qualify without reading these interesting lectures once through."—DUBLIN JOURNAL OF MEDICAL SCIENCE.
London: J. & A. Churchill, 11, New Burlington-street.

Price 6d., post free.

DIFFICULTIES under the INFECTIOUS DISEASE (NOTIFICATION) ACT, 1889.
*** The series of articles on "Difficulties under the Infectious Disease (Notification) Act," which recently appeared in the columns of THE LANCET, have been reprinted in pamphlet form, it being thought that many would care to possess, in a convenient shape, an elucidation of the principal points on which doubts and difficulties have arisen, and the various decisions and official interpretations which have been given with regard to them.
THE LANCET Offices, 423, Strand, W.C., and 1 & 2, Bedford-street (adjoining).

Now ready, profusely Illustrated, price 18s.

DEFORMITIES of the HUMAN FOOT. By W. J. WALSHAM, M.B., F.R.C.S., Senior Assistant Surgeon and Lecturer on Anatomy and Orthopædic Surgery, St. Bartholomew's Hospital. Assisted by W. KENT HUGHES, M.B. Lond.
Baillière, Tindall, & Cox, London, Paris, and Madrid.

Second Edition, revised and enlarged, price 7s. 6d.

DISEASES of the NOSE and PHARYNX. By J. B. BALL, M.D., M.R.C.P. Lond., Physician to and in Charge of the Throat and Nose Department, West London Hospital.
London: Baillière, Tindall, & Cox, King William-street, Strand.

Just out, demy 8vo, pp. 472, price 12s. 6d.

ESSAYS in HEART and LUNG DISEASE. By ARTHUR FOXWELL, M.A., M.D. Cantab., F.R.C.P. Lond., Physician to the Queen's Hospital, Birmingham.
"These admirable essays."—BRIT. MED. JOURN.
C. Griffin & Co., Ltd., Exeter-street, Strand, London.

Fourth Edition, price 4s.

ASTHMA and CHRONIC BRONCHITIS. By JOHN C. THOROWGOOD, M.D., F.R.C.P. Lond., Senior Physician to the City of London Hospital for Diseases of the Chest.
"In this are embodied the results of a very wide experience."—PROVINCIAL MEDICAL JOURNAL.
London: Baillière, Tindall, & Cox, King William-street, Strand.

VAN HOUTEN'S

PURE SOLUBLE

COCOA.

BEST & GOES FARTHEST.

By VAN HOUTEN'S Special Process of manufacture—

1. The excess of fat is removed and the other valuable constituents are increased, including the Albuminoids, the Theobromine, and the Phosphates.

2. The natural flavour and aroma are fully developed.

3. The solubility is greatly increased.

4. The tissues of the bean are softened and, with the fat or cocoa butter, rendered digestible and assimilable.

"VAN HOUTEN'S COCOA has formed the subject of special "analysis by some of the greatest European chemists, and all "concur in regarding it as a perfect beverage combining "STRENGTH, PURITY, and SOLUBILITY."—MEDICAL ANNUAL

Also,

CLUB-FOOT. Second Edition. 15s.

The SPINE (CURVATURES of). Second Edition. 10s. 6d.

The REPARATIVE PROCESS in HUMAN TENDONS. 6s. London: J. & A. Churchill.

NOW READY, profusely Illustrated, price 10s. 6d.

A GUIDE TO THE SELECTION AND ADAPTATION OF

ORTHOPÆDIC APPARATUS.

With a Detailed Description of their Salient Points.

By F. GUSTAV ERNST,

Orthopædic Mechanician.

"The illustrations of this work are excellent. The descriptions of the instruments are also good."—THE LANCET.

"..... We cannot but admire the ingenuity and skill shown in the instruments illustrated. Gentlemen who make a speciality of correcting deformities of the limbs or trunk will find the book a useful one for reference on the subject of apparatus."—MEDICAL PRESS.

"..... It is manifest, from the cleverly-designed apparatus illustrated and explained in this book, that Mr. Ernst is a thorough master of his vocation; and surgeons who may require mechanical support for their patients might consult Mr. Ernst's 'Guide' with great profit."—THE HOSPITAL GAZETTE.

2/6 net. THE 2/6 net.

CHEMIST'S COMPENDIUM.

AN INVALUABLE WORK OF REFERENCE FOR PHARMACISTS, CHEMISTS, & STUDENTS.

Comprises a Synopsis of B.P., the B.P.C. unofficial Formulary Modern Remedies (up-to-date), Milk Analysis, Urinalysis, Pharmaceutical Analysis, Photographic Formulæ, concise information on thirty other subjects, together with many useful tables, &c.

London: Whittaker & Co., Paternoster-square.

Fifth Edition, with Coloured Plates, price 12s. 6d.

DISEASES OF THE EAR.

By GEORGE P. FIELD, M.R.C.S.,

Aural Surgeon to St. Mary's Hospital and Dean of the Medical School.

"Very practical and helpful."—THE LANCET.

"It contains a novel feature. A number of plates are given on thick cardboard, the spot where the membrana tympani ought to be seen is perforated, and a coloured representation of the drum is pasted on behind. If the membrana be looked at through a speculum a more correct idea than any heretofore given will be the result."—MEDICAL TIMES AND GAZETTE.

"Forms an excellent guide for the practitioner or the student."—BRITISH MEDICAL JOURNAL.

"It is a practical treatise founded on vast clinical experience. The illustrations are excellent and helpful, the text is clear and concise, and the work as a whole is as complete and trustworthy as we could desire. We recommend it strongly to practitioners and students alike."—MEDICAL PRESS AND CIRCULAR.

"The fourth edition of this book was sold out in eight months."—FROM PREFACE.

London: Baillière, Tindall, & Cox, King William-street, Strand.

4

Now ready. Royal 8vo, 280 pp. Price 16s. With over 60 Original Illustrations by Chromo-lithography, Wood Engraving, and Photo-Micrographs.

DIPHTHERIA AND ITS ASSOCIATES.

By LENNOX BROWNE, F.R.C.S.E.,

Senior Surgeon to the Central London Throat, Nose, and Ear Hospital.

"An excellent monograph. ..... Will be a classic."—MEDICAL PRESS AND CIRCULAR.

Baillière, Tindall, & Cox, 20 & 21, King William-street, Strand

Now ready, price 10s. 6d.

DISEASES OF THE SKIN.

AN OUTLINE OF THE PRINCIPLES AND PRACTICE OF DERMATOLOGY.

By MALCOLM MORRIS,

Surgeon to the Skin Department, St. Mary's Hospital, London, &c. &c.

With 8 Chromo-Lithographs and 17 Woodcuts.

"Notwithstanding the number of excellent works on dermatology that have been recently published, Mr. Morris's book, from its compactness and the completeness with which it epitomises the latest suggestions in therapeutics of the skin, giving full references, will doubtless find a large field of usefulness."—BRITISH MEDICAL JOURNAL.

"We think the manual before us fully equal in reliability, and far superior in convenience of portability and reference, to any treatise that we know of already existing in the English, or, indeed, in any other language."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

"It is a reliable and impartial exposition of the subject, written from a strictly practical standpoint, and we commend it heartily to the profession. The volume is small and compact, but contains a great deal in a condensed form."—THE AMERICAN JOURNAL OF MEDICAL SCIENCES.

Cassell and Company, Limited, Ludgate-hill, London.

Cassell & Co., London.

PUBLISHED 1894.
Sixteenth Edition, much Enlarged, and revised up to date, price 12s. 6d.

SQUIRE'S COMPANION TO THE BRITISH PHARMACOPŒIA.

"No man who has the faintest aspiration to be in the van of pharmaceutical progress can afford to ignore the claims this exact and comprehensive epitome of pharmaceutical information has to a place at his elbow."—CHEMIST AND DRUGGIST.

"It is considerably ahead of the average text-books, and affords a valuable standard of reference to those who are anxious to keep pace with pharmaceutical advances, the illusions relating in many instances to current literature bearing the date of the present year."—THE LANCET.

"The present edition has evidently been revised with the greatest care, of which evidences are to be found almost on every page. Altogether, the improvements are so great that many of those who already possess the work will find it worth while to have the new issue."—PRACTITIONER.

London: J. & A. Churchill, 11, New Burlington-street, W.

Just published, with 2 Portraits, 8vo, price 12s. 6d.

THE LIFE OF

Sir HENRY HALFORD,

Bart., G.C.H., M.D., F.R.S.,
President of the Royal College of Physicians, Physician to George III., George IV., William IV., and to Her Majesty Queen Victoria.

By WILLIAM MUNK, M.D., F.S.A.,
Fellow and late Vice-President of the Royal College of Physicians of London.

London: LONGMANS, GREEN, & CO.

Now Ready, 3rd Edition, cloth gilt, cr. 8vo, with 5 *Coloured Plates*, 2s. 6d.

ON PERINÆORRHAPHY BY FLAP-SPLITTING.

By FANCOURT BARNES, M.D., F.R.S.E.,
Consulting Physician to the British Lying-in Hospital.

"Dr. Fancourt Barnes has succeeded in enriching this publication with illustrations far more instructive than those found under the heading of Perinæorrhaphy in most text-books."—BRIT. MED. JOUR.

"No obstetric practitioner should fail to read this little monograph."—THE INDIAN MEDICAL RECORD.

Clinical Lectures on Recent Surgery.

RADICAL CURE OF PROSTATIC OBSTRUCTION.
RADICAL CURE OF "IRREDUCIBLE HERNIA."
REMOVAL OF TUMOURS OF THE BLADDER, AND OTHER LECTURES.

By ARTHUR TREHERN NORTON, F.R.C.S.,
Senior Surgeon and Lecturer on Clinical Surgery at St. Mary's Hospital; Examiner in Surgery, London Society of Apothecaries.

"Mr. Norton has had much experience in the operative treatment of tumours of the bladder. The lectures on the radical cure of 'irreducible hernia' and on tumours of the bladder are really instructive and able contributions to surgical literature."—BRIT. MED. JOUR.

London: Baillière, Tindall, & Cox, King William-street, Strand.

Digitized by Google

Just published, price 12s. 6d.

DISEASES OF THE JOINTS & SPINE.

NEW EDITION.

By HOWARD MARSH,

Surgeon to, and Joint Lecturer on Surgery at, St. Bartholomew's Hospital; Consulting Surgeon to the Hospital for Sick Children; Examiner in Surgery at the University of Cambridge.

"It is clear, well arranged, full of practical work, and excellent alike for reading and for reference. The chapters on Charcot's disease, on bone-setters, and on the different forms of epiphysitis, are models of good clinical teaching: and the chapters on diseases of the spine, now first published, are admirable. The illustrations are well chosen; the whole book is the outcome of wide experience, careful observation, and what is called 'surgical instinct.'"—BRIT. MED. JOUR.

London: CASSELL & Co.

Now ready, Twelfth Edition, price 10s. 6d.

Spermatorrhœa; its Results and COMPLICATIONS.

Enlarged and reprinted from the original papers published in THE LANCET for 1852, and the "Medical Circular" for 1853. By J. L. MILTON, Surgeon to St. John's Hospital for Diseases of the Skin. Twelfth Edition, Illustrated with Engravings.

"To those desirous of acquiring a scientific knowledge of this affection, together with its treatment, we most heartily recommend this excellent treatise on the subject."—CANADA MED. AND SURG. JOUR. "The work is clearly and intelligibly written, and supplies a want."—GLASGOW MED. JOUR. "The treatment especially is founded on common sense in many important particulars."—EDIN. MED. JOUR. "We cordially recognise the completeness of his monograph."—MED. EXAM. "Should be read by every practitioner." "We earnestly commend the book."—N.Y. MED. JOUR.

London: Henry Renshaw, 356, Strand, W.C.

NOW READY, with Photographic and numerous Illustrations, Third Edition, enlarged, price 10s.

ON DISEASES OF THE EYE.

CHLOROFORM.

Chloroform (DUNCAN'S S.G. 1490) Non-decomposable.

This contains about 1 per cent. Absolute Alcohol, but in other respects is identical with our ordinary make (S.G. 1497). While this minute proportion of Alcohol in no way affects anæsthetic power, it renders the Chloroform **PRACTICALLY NON-DECOMPOSABLE.**

GELATINE CAPSULES, 1000 Varieties.

CASCARA CAPSULES. EASTON SYRUP CAPSULES.
GREGORY POWDER CAPSULES.

BLAUD PILL CAPSULES.

GUARANTEED STRENGTH.

At the request of medical men and others we have analysed a number of **BLAUD PILL CAPSULES** similar in size and colour to those of our own make. These capsules were stated to be each equal to three Blaud Pills, but our analyses showed that in no instance were they equal to more than 1½ Blaud Pills. This is neither fair to the medical man nor to his patient.

WE GUARANTEE OUR ONE, TWO, AND THREE PILL CAPSULES TO BE EQUAL RESPECTIVELY IN FERROUS CARBONATE TO ONE, TWO, AND THREE FRESHLY-PREPARED BLAUD PILLS. THEY HAVE ALSO THIS DISTINCT ADVANTAGE OVER PILLS, THAT THEY NEITHER OXIDISE NOR HARDEN.

DUNCAN'S SYRUP of the HYPOPHOSPHITES.

STABLE. ELEGANT. RELIABLE.

DUNCAN, FLOCKHART & CO.,

Manufacturing Chemists, EDINBURGH.

The above may be ordered through any Wholesale or Retail Druggist. The Capsules and Syrup are sold and dispensed by

Messrs. ROBERTS & CO., 76, New Bond Street, LONDON, W.

Wholesale from WM. EDWARDS & SON, 157, Queen Victoria Street, London, E.C.

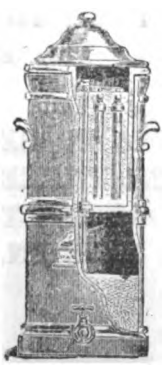
NESTLÉ'S CONDENSED SWISS MILK

THE RICHEST IN CREAM.

PERCENTAGE OF BUTTER FAT.



Six Samples of NESTLÉ'S MILK bought at random at six different Shops, and analyzed by Mr. OTTO HEHNER, late President of the Society of Public Analysts, contained AN AVERAGE OF

13·13 PER CENT. OF BUTTER FAT.

Sample Tin sent free to the Medical Profession on application to HENRI NESTLÉ, 48, Cannon Street, London, E.C.

THE PASTEUR GERM FILTER

(BOUGIE CHAMBERLAND).

The only Filter proved to afford Protection against Water-borne Disease.

This statement is made on the results officially recorded of the use of over 200,000 since 1888, which are confirmed by all Laboratory experiments. A précis of the evidence will be forwarded on application.

Made to give any required supply either with or without pressure.

THE EQUIFEX DISINFECTION APPLIANCES.

(GENESTE-HERSCHER, &c.. PATENTS).

STEAM STOVES.—The only stoves complying with the Recommendations of the International Sanitary Congress (Budapesth, 1894). Only Medal, Sanitary Institute Congress, Liverpool, 1893; Only Highest Award wherever exhibited.

SPRAYERS.—Cost a fraction of the time and expense required in use of SO^2, render disturbance of inmates unnecessary, and disinfect with certainty. Exclusively used by the Municipality of Paris and elsewhere.

PARTICULARS OF OTHER APPLIANCES ON APPLICATION.

SOLE LICENSEES AND MAKERS:

BOVRIL

BEEF

JELLY.

THE new package, adopted for this preparation, enables the beauty of the Jelly to be seen before opening. It is hermetically sealed, yet easier opened than any other package. Simply puncture the top; the vacuum is thus broken and the lid released. The Jelly will be found quite pure and free from all injurious contact with metal.

When this package once secures the attention of the Medical Profession no other will be used, as there is an increasing anxiety in the public mind about the action of tin and solder upon articles of food. **BEEF JELLY** is made from selected prime Ox Beef. It does not contain, as Bovril does, a high percentage of the albuminous or nitrogenous properties of meat; none of these jellies do, in spite of the veneration our parents had for calf's foot and other meat jellies.

This Essence of Beef can, however, be safely relied upon as an admirable stimulant and restorative in cases of nervous exhaustion, loss of blood, sudden shock, or in severe illness where no other food can be tolerated by the patient.

BOVRIL, LTD., FOOD SPECIALISTS, LONDON.

SALMON'S ABDOMINAL BELT.

In Silk Elastic and Thread ditto. From 25s. to 50s.

The Belt is light in texture, and affords a more lifting support than any hitherto made, completely supporting the lower part of the Abdomen. It is recommended in cases of Obesity, Tumour, Prolapsus Uteri, and during and after Pregnancy.

HENRY R. SALMON,
42, Beaumont-street, Upper Wimpole-street, London, W.
(from 87, Wimpole-street).

SALMON'S OBSTETRIC BINDER

For Immediate Use after Delivery. 6s. 6d., by post 6s 9d.

The Binder is a substitute for the towel generally used immediately after labour. It is made of strong linen and dispenses with the usual pinning. The advantages of the Binder are facility of application combined with comfort and greater efficiency. Measurement required, ordinary size of waist.

Each one stamped with name and address.

HENRY R. SALMON,
42, Beaumont-street, Upper Wimpole-street, London, W.
(from 87, Wimpole-street).

Established 1861.

Digitized by Google

Grove House, All Stretton, Church Stretton, Shropshire.

A PRIVATE HOME for the Care and Treatment of a limited number of Ladies mentally afflicted. Climate healthy and bracing.

Apply to Mrs. McLintock (widow of the late Dr. McLintock), the Resident Proprietress, or to the Medical Superintendent.

Mrs. McLintock has also in her private grounds a pretty detached Villa Residence, containing every modern convenience and comfort, where she is prepared to receive a Lady suffering from nervous affections, either with or without certificates, who will be attended by the Medical Consultant of the Grove House.

Barnwood House Hospital for Mental Diseases, Barnwood, near Gloucester.

Exclusively for Private Patients of the Upper and Middle Classes. This Institution is devoted to the Care and Treatment of persons of both sexes at moderate rates of payment. The terms vary according to the requirements of the patients, who can have private rooms and special attendants, or be accommodated in Detached Villas and in the Branch Convalescent Establishment on the hills. Under special circumstances the rates of payment may be greatly reduced by the Committee.—For further information apply to J. G. Soutar, M.B., the Med. Supt.

St. Luke's Hospital, London, E.C.

Established 1751.

This Hospital was established for the Treatment of Mental Diseases of the Upper-middle and Middle Classes, for whom there is no statutory relief. Preference is given to acute cases, and these are admitted either gratuitously or on payment of a weekly sum varying from 14s. to 30s., according to the circumstances of each; and chronic cases can only be admitted at the higher rates. Patients are eligible for admission from any part of the United Kingdom.

Forms of application may be had from, and inquiries addressed to, the Secretary, at the Hospital.

PERCY DE BATHE, M.A., Secretary.

Warneford Asylum, Oxford.—This

Asylum, for the care and treatment of the Insane of both sexes of the Middle and Upper Classes, is pleasantly situated on Headlington-hill, near Oxford, and has been recently enlarged. The grounds are extensive, and cricket, tennis, billiards, dances, and other amusements are amply provided. There are now vacancies for patients at moderate charges. Voluntary patients can also be received.—For particulars apply to the Medical Superintendent, Dr. BYWATER WARD.

SPRINGFIELD HOUSE PRIVATE ASYLUM, BEDFORD.

For forms of admission, address, DAVID BOWER, M.D., as above.

(Dr. B. attends at 5, Duchess-street, Portland-place, W., on Tuesdays, from 3 to 4.)

Terms 2½ guineas per week.

The extensions and reconstruction being now completed, there are Vacancies on each side.

INTEMPERANCE.

Buxton House, Earl's Colne, Essex.—

PRIVATE HOME for SIX LADIES. Nineteen years' experience. Very satisfactory results. Excellent Medical references. Inspection by applicants welcomed. Terms from 2 to 3½ guineas weekly.

Medical Attendant, J. TAYLOR, Esq., M.R.C.S.Lond., L.S.A.

Address, Mrs. or Miss PUDNEY.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

President: The Right Hon. the Earl MANVERS.

This Institution is for the reception of a limited number of Private Patients of Both Sexes, of the Upper and Middle Classes only, at moderate rates of payment. It is pleasantly situated on an eminence a short distance from Nottingham, and commands an extensive view of the surrounding country; and from its singularly healthy position affords every facility for the relief and cure of those mentally afflicted.

Particulars as to terms, &c., may be obtained from Dr. TATE, the Medical Superintendent.

Private Home for the Treatment of

INSANE LADIES,

ASHBROOK HALL, HOLLINGTON,

within half an hour's walk of St. Leonards-on-Sea, conducted by the Widow of the late Samual Hitch, M.D., formerly of Sandywell-park, near Cheltenham, for many years Physician to the General Lunatic Asylum for the County of Gloucester.

Station: Warrior-square, St. Leonards. Telegraph Office: Hollington.

For particulars and terms apply to

Mrs. LETITIA A. HITCH.

Church Stretton Asylum, Stretton

House, Church Stretton, Salop. Established 1853. (For Gentlemen only.) 600 ft. above sea level. Bracing air, farm, extensive grounds, and every facility for occupation and amusement; 4½ hours from London. Terms moderate. Suites of rooms for first-class cases.

St. Andrew's Hospital for Mental DISEASES, NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President—The Right Honble. the EARL SPENCER, K.G.

Chairman of the Committee of Management—The Most Honble. the Marquis of NORTHAMPTON, K.G.

The Institution is pleasantly situated in a healthy locality, one mile from the London and North-Western or Midland lines, and one and a half hour only from London.

It is surrounded by more than 100 acres of pleasure grounds.

Great care is exercised in the classification of the Patients according to their habits and different degrees of mental aberration, so that those who are quiet or convalescent may not associate with those whose minds are more affected.

Ample means of occupation and amusement are provided, including Cricket, Croquet, Lawn Tennis, and Archery. There are also Billiard Rooms, and a large Recreation Hall and Theatre.

The terms vary from 25s. to £4 4s. week, according to the requirements of the case.

Patients paying higher rates can have Special Attendants, Horses, and Carriages; and Private Rooms in the hospital; or in detached villas in the grounds of the hospital; or at Moulton Park, a branch establishment, two miles from the hospital.

There is also a Seaside House, to which Patients may be sent.

For further information apply to the Medical Superintendent.

NEWLANDS HOUSE,

THE SCHOLASTIC, CLERICAL, & MEDICAL ASSOCIATION, LTD.

MEDICAL DEPARTMENT.

This Association was established in 1880 as a Limited Liability Company under the direction of professional men, its object being the creation of a RESPONSIBLE and THOROUGHLY TRUSTWORTHY Agency. The Medical Department has met with so great success that it has been found necessary for one of the Managing Directors (Mr. G. B. Stocker) to devote his whole attention thereto; and he has the assistance of an experienced Medical Accountant and a large staff of clerks. Further, a Board composed entirely of gentlemen of high standing in the Medical Profession has been appointed, and to them matters of dispute and complaint are referred.

The Association undertakes the SALE of PRACTICES and PARTNERSHIPS; the Introduction of LOCUM TENENS and ASSISTANTS; MEDICAL ACCOUNTANCY (by a duly qualified Medical Accountant); INVESTIGATION and VALUATION of Practices, &c.; POSTING BOOKS and sending out Bills, &c., &c.

A Pamphlet relating to the Medical Department, with the names of the "Directors" and "The Medical Advising Board," and terms, will be sent on application to—MR. G. B. STOCKER, MANAGING DIRECTOR, 8, LANCASTER PLACE, STRAND, W.C.

Telegraphic Address—"Triform, London."

FOR SALE.

(1) **EASTERN COUNTIES.**—UNOPPOSED PRACTICE.—Very old established, and held by present incumbent twenty-one years. The average cash receipts are over £800 per annum, including £260 from appointments. Two horses required. Small but convenient house, with garden and stabling, which must be purchased with the practice. Premium for practice and house £1650.

(2) **SOUTH WEST OF ENGLAND.**—Country Town PRACTICE of about £1000 per annum, including club appointments of about £200. Visiting fees 2s. 6d. to 10s. 6d. Six months introduction. Premium £1260.

(3) **LONDON, W.**—PARTNERSHIP in a mixed Practice (largely ready money). Cash receipts for 1895 will amount to not less than £1150. Visiting fees 1s. 6d. to £1 1s. Midwifery fees, £1 11s. 6d. and £2 2s., about forty cases annually. One-half Share would be sold for £700, or one-third for £450, with prospect of succession to whole in a few years.

(4) **LANCASHIRE.**—A third PARTNER is required for middle and working-class PRACTICE in a manufacturing town. £500 per annum guaranteed for two years. Premium £1040.

(5) **NORTH OF ENGLAND.**—A working and middle-class PRACTICE in a large seaport town. The cash receipts for 1895 at the rate of £1350, including club appointments worth £114. Visiting fees 2s. 6d. to 3s. 6d. Midwifery fees 15s. to £1 1s.; over 200 cases annually. One horse. Good house with stabling; rent £85 per annum. Premium £1865.

(6) **WEST OF LONDON.**—Mixed PRACTICE in a main thoroughfare of about £400 per annum. Visiting fees 1s. 6d. to 3s. 6d. Midwifery fees 15s. to £2 2s.; about 100 cases annually. Rent £55; premium £400, to include lamp, drugs, fixtures, &c.

(7) **EASTERN COUNTIES.**—PARTNERSHIP, with view to Succession, in a country Practice of £1000 per annum. Price, for one-third share, £450. Small house, rent £16, suitable for a bachelor.

(8) PARTNERSHIP (with View to Succession in two years) in a Practice of over £2000 per annum, including £500 from good appointments. Large and important town. Middle and working class. Purchaser must have £3000, or security for that amount.

(9) **LARGE TOWN.**—NORTH MIDLANDS.—PRACTICE of about £800 per annum, including clubs of £120. No horse required. Rent £50. Price one year's purchase.

(10) PARTNERSHIP, with view to Succession in two years to a Practice of over £1000 per annum, in a large town in the north of England. Good working- and middle-class. Price for one-third Share £600.

(11) **LONDON, N.**—Old-established Middle-class PRACTICE of £1000 per annum. Visiting fees chiefly 3s. 6d. and 5s. No midwifery under £1 1s. Ten-roomed house. Six months' introduction. Price £1125.

(12) **SOUTH-WESTERN SUBURB.**—PRACTICE of £650 per annum (about one-fourth ready money). Visiting fees 2s. 6d. to 5s. Midwifery £1 1s. upwards. Working expenses very light. House (eight rooms) £40 per annum. Price one and a quarter year's purchase.

(13) PARTNERSHIP in an old-established PRACTICE of £1400 to £1500, largely amongst well-to-do working- and middle-class patients in a small town in the South-west of England. One-third share at first and a half in three years. One and a half year's purchase.

(14) **LONDON, S.E.**—PARTNERSHIP with view to Succession in twelve months. A capital Middle-class Practice of about £1500 per annum. Old established. Visiting fees mostly 3s. 6d. Midwifery fees chiefly 2 and 2½ guineas. Good house, in main thoroughfare. Rent £75 per annum. Premium £1850, with twelve months' partnership introduction.

(15) PARTNERSHIP in a good-class outlying suburban Practice of £875 per annum, with view to succession in two years. Price £1033, and a similar sum upon succession.

(16) **HOME COUNTIES.**—Unopposed PRACTICE of over £400 in a very pleasant neighbourhood. Very good house, garden, paddock, &c.; rent £80. Premium £650. Purchaser should have small private means or resident patient.

(17) **LONDON, N.W.**—Suburban PRACTICE of £500 to £600 per annum, non-dispensing. Scope increase. Fine house, stabling, and garden, which must be purchased. Inclusive price £2250, £1000 of which may be left on mortgage.

(18) **LONDON NORTHERN SUBURB.**—Good Middle-class PRACTICE of over £1100 per annum. Visiting fees, 2s. 6d. to 7s. 6d. Midwifery, £1 1s. to £3 3s. One horse required. No assistant. Very good house with stabling and garden. Rent £100 per annum. Premium, one and a quarter year's purchase.

(19) **OUTLYING SUBURB, E.**—PRACTICE of £610. Cash receipts nearly all ready money. Price £550, including drugs and surgery fittings. Exceptionally good residence. Neighbourhood rapidly increasing.

FOR SALE (*continued*).

(20) **LONDON, N.**—SUBURBAN PRACTICE. Receipts for last twelve months, £446. Visiting fees 2s. 6d. to 5s. (a few at 1s. 6d.). No horse. The house is well situated; large garden and stabling, rent £72 (stabling let off for £30 per annum). Premium £300 to £350.

(21) **LANCS.**—PRACTICE of £350 to £400 in a small manufacturing town for Sale through ill health of present incumbent. Expenses light. Rent of house £40. Premium £300.

(22) **LANCS.**—PRACTICE in a manufacturing district. Cash receipts last year £550. Visiting fees 3s. 6d., midwifery 15s. to 1½ gs. Good house, rent £40. Premium £500, part payable by instalments if secured.

(23) **MIDLANDS.**—Old-established PRACTICE of about £400 in one of the smaller manufacturing towns. Good small hospital. Ten-roomed house, well situated; rent £40. Premium £500.

(24) **SOUTH LONDON.**—PRACTICE in a thickly populated residential suburb. Cash receipts average £724 per annum. Club appointments £85 per annum. Fees 1s. to 5s.; midwifery mostly £1 1s., sixty to seventy cases annually. Rent of surgery £60 per annum (15s. per week let off). Taking over of private residence optional. Premium £600.

(25) **NORTH MIDLANDS.**—Unopposed country PRACTICE of about £450, including appointments of over £100. Rent of house (four bedrooms), with stabling and small garden, £22. Premium £560.

(26) UNOPPOSED COUNTRY PRACTICE in WALES (not necessary to speak Welsh) of over £300, with scope to £600 or £700. Agricultural district. Premium £250. Suitable for a bachelor.

(27) **SOUTHERN COUNTY.**—NUCLEUS of about £250 in a small market town. Rent and living cheap. Premium £150.

(28) **LONDON, E.C.**—DISPENSARY PRACTICE of about £400 per annum. Fees at surgery mostly 1s. and 1s. 6d. Midwifery mostly £1 1s. Immediate sale necessary. Price only £150.

(29) **CORNWALL.**—UNOPPOSED COUNTRY PRACTICE of £330 per annum, including transferable appointments (parish and club). One horse. Rent of house (four bedrooms), with stabling, garden, and field, £14. Premium £400, to include drugs, horse, &c.

(30) DISPENSARY PRACTICE.—PARTNERSHIP.—TWO-THIRDS SHARE of a PRACTICE of about £800 per annum, with attendance only four days a week. Premium £650.

(31) **OUTLYING SUBURB** (East of London). PRACTICE of over £1200 per annum, cash receipts. Visiting fees 1s. 6d. to 2s. Midwifery fees, 15s. 6d. to 21s.; about 150 cases. Corner house, rent £55. Premium £1050; part by instalments.

(32) **NORTH WALES.**—Unopposed PRACTICE of £600 per annum, including appointments over £300. There is scope for increase. One horse. Small but comfortable house with good garden and stabling. Premium £400. A knowledge of Welsh absolutely essential.

WANTED TO PURCHASE.

(33) **WANTED, a COUNTRY PRACTICE or PARTNERSHIP of £800 per annum upward, within sixty miles of London. Purchaser is a M.B., B.S., T.C.D. Married, experienced, and can invest ample capital.**

(34) **A GOOD PARTNERSHIP** (income of £700 or more to begin with) in a Practice with partnership introduction in London or large Provincial Town with hospital. Purchaser is a graduate in Arts and Medicine of Oxford, and can invest up to £5000.

MEDICAL TRANSFER AND PARTNERSHIP.

32, Ludgate-hill.

Messrs. Orridge & Co., Medical Transfer Agents, Referees, and Valuers, in offering their services to the Profession, have pleasure in referring to the fact that for ABOUT HALF A CENTURY the name of Mr. ORRIDGE has been known in the advertising columns of the leading medical journals, and that a very large proportion of the Medical Men throughout the kingdom have confided their interests in the adjustment of PARTNERSHIPS and TRANSFERS to their care.

Purchasers who will communicate (confidentially) the NATURE and EXTENT of their wishes regarding investment can be apprised of appropriate opportunities as they occur.

On occasions where ADVICE is required in forming a correct conclusion as to the worth or eligibility of a Practice, Messrs. ORRIDGE & Co. trust that their familiarity with the various contingencies that govern value will be found of considerable service to those by whom they are employed. N.B.—No charge is made to purchasers.

Assistants and Locum Tenens supplied on the shortest notice. Apply to G. B. Stocker, Esq., Secretary, Medical &c. Assn., Ld., 8, Lancaster-place, Strand, W.C. The rule of the Association is that no Assistant shall be recommended till direct inquiries have been made as to his antecedents. Names of the Committee of Management and descriptive pamphlet on application."—Telegraphic address, "Triform, London."

Locum Tenens or temporary Assistant.—A registered Medical Practitioner of experience, who is well received by all classes, wishes to act as above in Jersey or South of England.—Address, Zeta, THE LANCET Office, 423, Strand, W.C.

Fully qualified Medical Man having spare time from 12 to 6 P.M. daily, would either take charge of Surgery or Visit during these hours. Terms moderate. Resident in London.—Address, M. M., THE LANCET Office, 423, Strand, W.C.

Assistants and Medical Men failing to obtain what they require should apply to ADAMS & PARKES (B.A. Cantab.), Medical Agents, 14, Southampton-street, Strand. No charges are made for unsuccessful service.

An M.D.Edin., not at present in practice, but wishing to keep in touch with professional work, would give some SERVICES in return for board and lodging, to a Medical Man, with whom he could have the opportunity of seeing some practice. Easy access to a good hospital desirable. — Address, Stethoscope, The LANCET Office, 423, Strand, W.C.

Required, by an M.R.C.S., L.R.C.P. (St. Bart.'s), aged twenty-seven, married, MANAGEMENT of a Branch Practice, or out-door ASSISTANTSHIP in good class Practice. Disengaged January 7th.—Address, Tempest, THE LANCET Office, 423, Strand, W.C.

A doubly qualified Gentleman, with several years' experience, disengaged shortly, would like a permanent ASSISTANTSHIP (South preferred). Ride and drive; single. References to present and past principals.—Please address, stating terms and class of Practice, to M.R.C.S., care of Dr. Godfrey, 5, Compton-terrace, Highbury, N.

Trebly-qualified, registered Gentleman, age thirty-three, desires ASSISTANCY or Management of Branch. Experienced in every class of practice; very strictly temperate; popular with patients; energetic and fond of work; good appearance; Churchman; native of Derbyshire. Good references. At liberty for immediate engagement.—Address, stating remuneration, Dr. Rhodes, 21, Indlewood-grove, Upper Brook-street, Manchester.

Assistant (single, in-door, qualified) wanted at once, to Visit, Dispense, and keep Books.—Please apply by letter, stating age and what salary required, to W. R. Hains, 1, Ashchurch-terrace, Shepherd's-bush.

Wanted, in Colliery Practice in Glamorganshire, qualified ASSISTANT, out-door, to Visit, Dispense, &c. Usual bond.—Apply, giving references and salary required, to Gwalia, THE LANCET Office, 423, Strand, W.C.

Wanted, for abroad, a first-class Man as ASSISTANT. Salary £240, £250, and £260 per annum for the first, second and third years respectively, with free board, lodging, washing, &c. Protestant. Abstainer. Unmarried. Not under twenty-five. Must have surgical ability, experience, and highest references as to character, reliability, and disposition. Satisfactory English references given.—For fuller details address, M.D., THE LANCET Office, 423, Strand, W.C.

Wanted, a well-qualified out-door ASSISTANT, to Visit, Dispense, and attend Midwifery.—For further particulars apply, Beech House, Middleton, near Manchester.

Wanted, a fully qualified Assistant (in-door), to Visit, Dispense, and attend Midwifery.—Apply, sending testimonials, photo, &c., and stating salary, to West Riding, THE LANCET Office, 423, Strand, W.C.

Wanted, early in January, an ASSISTANCY, either in-door or out-door, by trebly qualified man, well connected and generally well received by patients. Would suit an elderly gentleman or one in failing health; is not afraid of work. Single; age thirty; good horseman. Three years' experience of Club and General Practice.—Apply, stating salary, Ycrep, Vicarage, Bamton.

Usual Bond.—Richardson's Medical ASSISTANT'S AGREEMENT for SERVICES. "This is a form of agreement which principals may find useful in engaging Assistants. It is very explicit."—THE LANCET, February 9th, 1895. It contains all the conditions of the usual bond as well as several useful and necessary clauses. Stamped copies, price 11s. Entered at the Stationers' Hall, and can only be obtained from RICHARDSON BROS. & CO., Medical Agents, Liverpool. ASSISTANTS and LOCUM TENENS supplied.

NOTICE.

WITH regard to advertisements affecting unqualified assistants, the Proprietors of THE LANCET think it right to point out that they obviously cannot guarantee that each individual advertiser offers his services under such conditions as would be approved by the General Medical Council. The Proprietors consider that inconvenience to practitioners and hardship to unqualified assistants may be caused by the entire exclusion of these advertisements from the columns of THE LANCET. The General Medical Council do not, it is understood, object to unqualified assistants being employed by practitioners when resident in or near their employers' houses, but the Council will not allow unqualified persons to conduct branch practices, or dispensaries which are situated at a distance from the principal's house and are not under his immediate supervision.

Wanted, Student who can Dispense, Visit occasionally, and attend Midwifery case if required. Plenty of time for reading. Board, lodging, and washing in lieu of salary.—Address, Yorkshire, THE LANCET Office, 423, Strand, W.C.

Wanted, in a Country Practice, a Gentleman to Dispense, and occasionally Visit and attend Midwifery. Plenty of time for reading.—Address, stating salary (in- and out-doors), references, &c., Kirkwood, THE LANCET Office, 423, Strand, W.C.

CULLETON'S HERALDIC OFFICE,

The PUMP HOUSE, LAKE HOTEL, and BATHS,

LLANGAMMARCH WELLS, CENTRAL WALES.

Telegraphic Address—"BARIUM, LLANGAMMARCH WELLS."] **[For Terms apply to MANAGERESS.**

(CENTRAL WALES.) **BARIUM SPRINGS.** (ALTITUDE 600 ft.)

THE LLANGAMMARCH WELLS, PUMP HOUSE, LAKE HOTEL AND BATHS. This first-class Hotel standing in its own ornamental grounds, is situated on the slope of the Eppynt Hills, looking down one of the most beautiful valleys of Wales. All the rooms have been furnished with every regard to the comfort of visitors; special attention has also been given to the sanitary drainage and water supply, which has been carried out on the most modern principles. There is splendid Salmon and Trout Fishing to be obtained in the River Irfon, over two miles of this charming tributary of the Wye flowing through the hotel grounds and is reserved for visitors, who also have the privilege of shooting over several thousand acres of Mountain and Moorland, while the picturesque lake affords every facility for boating.

It has been stated in a recently published work on Chronic Diseases of the Heart, as the result of experiment, that the Mineral Waters of Llangammarch, employed as baths as well as taken internally, exercise healing effects similar to those of the celebrated springs of Nauheim in Germany. The Proprietors of the Llangammarch Wells have secured the attendance at the Pump Room and Bath House of a Physician, who is practically acquainted with the methods employed by Dr. Schott at Nauheim for the relief of Gout, Rheumatism, and Heart Affections, during the Season from June to October.

RESULT OF ANALYSIS BY DR. DUPRÉ, August, 1883:—

"A Sample contained in two Winchester quart bottles, stoppered, from Llangammarch Springs. The water is clear, slightly saline taste.

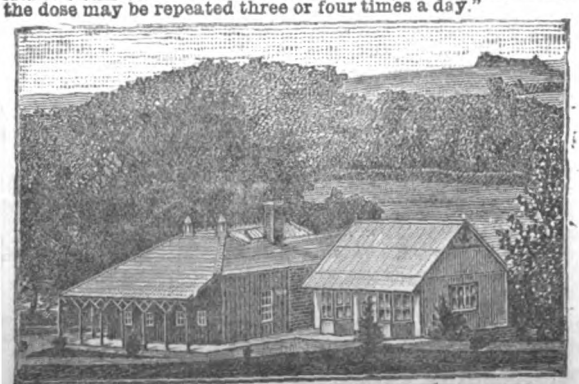
Chloride of Sodium	189·56
Chloride of Calcium	84·66
Chloride of Magnesium	24·31
CHLORIDE OF BARIUM	6·26
Carbonate of Calcium	2·60
Silicia	1·40
	308·89 grains per gallon.

"The characteristic feature of the water is the presence of a notable quantity of **BARIUM CHLORIDE** and a consequent total absence of sulphates. **BARIUM** is a rare constituent of Mineral Waters.

"*Westminster Hospital, August 23rd, 1883.*" "A. DUPRÉ.

As a remedial agent **BARIUM** ranks high in cases of Strumous Disease in its protean forms, Glandular Enlargements, Scrofula, Chronic Rheumatism, Epilepsy, and Diseases of the Heart. It is also useful in other Diseases, such as Liver Derangements, &c.

Extract from THE LANCET, Nov. 24th, 1894:—



"A sample of the barium water was obtained, sealed, and despatched to THE LANCET Laboratory for detailed examination, and the results may be compared with the analysis of the sample first submitted. In the following analyses Sample 1 is the sample obtained by ourselves, and Sample 2 the sample first submitted. The results are expressed in grains per gallon (70,000 grains):—

	No. 1.		No. 2.
Chloride of barium	6·749	.....	6·490
Chloride of sodium	186·200	.....	185·900
Chloride of calcium	85·160	.....	85·470
Chloride of magnesium	20·100	.....	20·315
Chloride of lithium	0·847	.....	0·910
Chloride of ammonium	0·262	.....	0·262
Alumina and silica	3·340	.....	3·100
Bromine as bromide	Distinct traces	.....	Distinct traces
Total mineral matters	302·658	.....	302·447

"It is important and interesting to observe that the quantity of barium salt has varied only within very small limits during the last ten years, as in 1883 Dr. Dupré made an analysis, in which he found 6·26 grains of barium chloride per gallon. The amount of chloride of barium may therefore be fairly regarded as constant—a fact which is of especial importance in view of the powerful action of barium salts. ..... The quantity of barium present renders the internal administration of the Llangammarch waters quite safe, and no harm could result from drinking the water in reasonably large amounts. One tumblerful is a sufficient dose in most cases and two tumblerfuls should seldom, if ever, be exceeded, though the dose may be repeated three or four times a day."

THE LAKE, LLANGAMMARCH WELLS.

THE BARIUM SPRINGS.

Extract from the MEDICAL ANNUAL, 1890:—

"*Heart—new treatment.*—Continued trial has affirmed the efficacy of **BARIUM CHLORIDE** as a cardiac tonic. It has been found to slacken and regulate the heart-beat and to augment the amplitude of the pulse without producing as much increase in the arterial tension as does digitalis. Da Costa and Hare have both added their experience of the drug to the published statements of Boelm, Kobert, Bacey, Lauder Brunton, and Bartholm on this subject. Da Costa finds that it can be taken for a long time without disordering the stomach, that it has some diuretic action, and that it has the valuable property of lessening cardiac pain—a statement which Hare confirms. The latter has obtained good results from the use of Barium Chloride in both mitral diseases, in acute dilatation of the heart, and in functional derangement of the heart. H. A. Haze (JOURNAL DE MÉDECINE DE PARIS) has obtained good results from its use in all the above diseases, and also in aortic diseases.

"*Glandular Enlargement.*—An eminent London Physician writes:—'My experience in the two cases which I sent to Llangammarch has been eminently satisfactory, and the well-recognised efficacy of the Kreuznach waters in glandular enlargement encourages the hope that the waters of Llangammarch may prove to be of signal and widespread benefit in the future.'"

BARIUM WATER is supplied, both Still and Aërated, by the London Agents—

INGRAM & ROYLE, Ltd., 52, Farringdon St., E.C. ["Telegraphic Address: "Ingram Royle, London

PRINTED and PUBLISHED by the REGISTERED PROPRIETORS, at No. 423, Strand, and Nos. 1 and 2, Bedford-street, adjoining, in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London, and sold by all Booksellers and Newsvendors in Great Britain and Ireland and the Colonies.—Saturday, Dec. 28th, 1895.

ELEGANT PHARMACEUTICAL PREPARATIONS OF WM. R. WARNER & CO.

SILVER MEDAL for Excellence, PARIS, 1889.

INGLUVIN
(REGISTERED).

Per Ounce 4s. 0d.

INGLUVIN in SPAIN.—The following letter on Ingluvin was recently received by Vilanova, Hermanas, & Co., of Barcelona, from Dr. F. VIDAL SOLARES:—

"I have to acknowledge duly having received the Ingluvin which you were good enough to send me for the purpose of proving the therapeutic effects of this excellent medicine amongst my clients, from Messrs. W. R. Warner & Co.

"The results which I have obtained in my dispensary for sick children, together with my private cases, have been extremely satisfactory. In fact, I have treated various cases of dyspepsia, in which the patients, fully prostrated and without power to digest their food, have, thanks to the use of Ingluvin, been rapidly cured.

"In the case of 'apepsia,' or loss of appetite, in children, accompanied with diarrhœa, I have obtained good results from the use of Ingluvin, which therapeutic agent is extracted by the house of Warner & Co. from the stomach of the chicken.

"I have also found Ingluvin useful in the organic complaints of the stomach, and in the indomitable vomiting and painful dyspepsia to which women are subject during pregnancy. I have employed the agent, moreover, in the convalescent state of many patients, when I have not only noted the alteration of the gastric secretions, but of the extreme instability of the stomach.

"I have not the least doubt that the Ingluvin, of which you have the sale in Spain, will in a short time become a substitute for pepsin on account of its being more active than the latter; but, as is only logical, you should obtain a rapid result by bringing this preparation to be known in all Spain by the opportune measure you usually adopt.

"Hoping you will have the justice to manifest to the manufacturer the results I have obtained in my practice with Ingluvin, I am," &c.

PARVULES
(REGISTERED).

A new class of medicines (minute pills), designed for the administration of small doses for frequent repetition in cases of children and adults. It is claimed by some practitioners that small doses given at short intervals exert a more salutary effect. The elegance and efficiency of Parvules leave nothing to be desired. The dose of any of the Parvules will vary from one to four, according to age or the frequency of their administration. For instance, one Parvule every hour, or two every two hours, or three every three hours, and so on for adults. For children, one three times a day is the minimum dose. We mention Parvules as a class of remedies very highly esteemed by Physicians for their unvarying activity, solubility, and accuracy. (Parvules are not pink Granules.) See Parvules of Aloin, 1.10 gr.; Parvules of Calomel, 1.20 gr.; Parvules of Podophyllin, 1.40 gr.

COATED PILLS (SOLUBLE).

Pills and their Coating.—An experience of over a quarter of a century has demonstrated that sugar, as applied by our process without heat, is the most suitable and soluble substance for coating pills. In this assertion we are sustained by the highest medical authorities, who have tried them repeatedly and verified our claims. Our principal claims are solubility and compatibility under all circumstances. This is not so with gelatin coating, which is insoluble where coffee, astringent fruits, or wines containing tannin are taken. These facts entitle us to the confidence of the Medical Profession, and justify us in asking assistance in our endeavours to maintain the integrity of WARNER & Co.'s Preparations.

N.B.—☞ It is pre-eminently the right of Physicians to designate a choice. The leading Druggists throughout the country keep Warner & Co.'s Preparations.—W. R. WARNER & CO.

BROMIDIA.

"ALTHOUGH opposed to the use of pharmaceutical specialities I was struck with the formula of **BROMIDIA** (Battle), and, knowing the action of its ingredients, could not bring myself to believe in its possessing greater therapeutic power than its component parts. However, I determined to try it in a severe case of Mammary Neuralgia which had proved refractory to an infinitude of other remedies. The result was brilliant, and far beyond my expectations. I then made experiments with a preparation made according to the formula of **BROMIDIA** by an experienced pharmacist, but whether due to the greater purity of your drugs, or special mode of combining, the results were not to be compared with those of **BROMIDIA** (Battle).

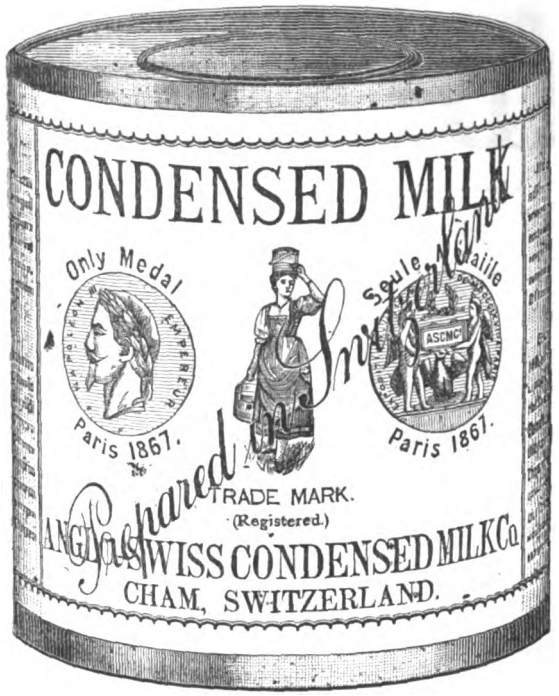
"DR. ORAZIO SATARIANO.

"*Barrafranca, Italy.*"

CAUTION.

The great reputation of BROMIDIA has frequently caused cheap and inefficient imitations to be dispensed as Bromidia. Some of these substitutes are not only worthless, but absolutely harmful.

As a precaution, it is not only necessary to specify BATTLE'S BROMIDIA, but also to see that the patient obtains the genuine preparation.



A Sample Bottle of BROMIDIA and Pamphlet will be forwarded free of charge to Medical Men on application to

ROBERTS & CO., 76, New Bond Street, London.

Cadbury's COCOA.

No Alkalies used, as in many of the so-called "pure" foreign cocoas.

THE LANCET, referring to a thorough recent examination of Cadbury's Cocoa, says :—"The results leave no doubt of its purity and excellence, and show that there has been no treatment with fixed alkalies, or with ammonia. . . It represents therefore the standard of highest purity at present attainable in regard to cocoa."

OSTEOMALACIA

SUCCESSFULLY TREATED BY

EXTRACT OF BONE MARROW.

AT the autumnal meeting of the North of England Branch of the British Medical Association, Dr. ALLISON of Newcastle reported in detail a severe and prolonged case of Osteomalacia, which he treated "with satisfactory results by Glycerine Extract of Bone Marrow (BRADY & MARTIN)." The disease first commenced in the patient (a woman forty-three years of age) when she was thirteen, and for over twenty years before the Bone Marrow treatment was adopted she had been a bed ridden cripple. The full history of the case and the condition of the patient, before and after treatment, are detailed in the NORTHUMBERLAND AND DURHAM MEDICAL JOURNAL for October, 1895. The Bone Marrow Extract was given in doses of half to one and a half drachms three times daily after food, and Dr. ALLISON reports that:—

"Improvement was felt on taking the second dose, 'a feeling of warmth going through the bones,' and the severe pains from which the patient suffered (the nasal first) began, after preliminary intensity, to gradually pass away, and have now entirely disappeared."

"Visible improvement soon appeared, also the appearance of the patient brightening considerably, and deformity began markedly and progressively to disappear—the parts last affected, generally speaking, improving first."

"But the most striking improvement was shown in the limbs. In the first week the bones of the extremities commenced, and have continued since, to rotate into place, the rigid articulations 'going off in cracks' audible to the patient and other persons in the room, and causing sharp pain for the time. Latterly, however, movements towards the normal have become practically painless."

"Consequent on these changes the patient has now comparatively good use of all her limbs, voluntary activity having returned to all, and she is able to grasp the bedhead with her left hand and touch it with her right, lying in the old attitude on her back."

"In another direction, too, improvement is shown. So much strength has returned to the leg-bones that the patient feels they are quite able to support the trunk; but the patellæ being still quite clear of their proper articular surfaces, until they become replaced, although flexion is free, the legs cannot be extended sufficiently to permit of standing or walking. The patient, notwithstanding, is making efforts to regain the upright position."

Measurements to show the marked change in the patient's condition are given, and Dr. ALLISON sums up the case as possessing the following points of interest:—

"1. The early onset and chronic course of the disease."
"2. Its being associated with puberty, but not with pregnancy."
"3. There being great deformity, but no fracture of the bones."
"4. The pelvis having given way behind rather than in front."
"5. The association of extreme kyphosis, with marked lateral curvature."
"6. The general course of the disease from below upward, most marked in the right limbs, and the correspondence of deformity in the lower and upper extremities."
"7. The *striking effects of the treatment*, and the tendency of the skeleton, under its influence, to revert, without the aid of the muscular system, to the normal type. The urine shows a decrease in the quantity of the earthy phosphates, but the total quantity of phosphates is about the same."

Dr. ALLISON concludes by stating that in view of the terrible condition and the hopelessness of medical and surgical treatment of this formidable disease he is justified in bringing this *promising form of treatment* to the notice of the medical profession.

Glycerine Extract of Bone Marrow (Brady & Martin) used in the above case. Price 1/- per ounce.
Tabellæ of Bone Marrow. Price 5/- per 100.

Bone Marrow Extract has also been used in the treatment of Pernicious Anæmia, Chlorosis, and Anæmia, and would probably be of use in all cases in which there is defective nutrition dependant on imperfect blood metabolism.

BRADY & MARTIN,

MANUFACTURING PHARMACISTS AND ANALYTICAL CHEMISTS, NEWCASTLE-ON-TYNE.

NOTE.—BRADY and MARTIN are the original makers of Thyroid preparations, and the first English Pharmacists to make Animal Extracts. They do not, however, make them as secret preparations or proprietary articles, every detail of their composition and manufacture having been described either in the original papers by the medical men who have written on the uses of the Extracts, or else in the Pharmaceutical Journals in papers by the partners (Mr. N. H. MARTIN and Mr. C. E. STUART, B.Sc.), neither do BRADY & MARTIN advertise these preparations to chemists and the general public, nor put them up in forms intended to foster the pernicious habit of self-medication on the part of patients. The Extracts are only supplied to and through medical men, to whom every information and assistance—pharmaceutical and chemical—will be given in carrying out investigations upon the scientific preparation of remedies for the treatment of disease.

THE PHONENDOSCOPE.

A New Instrument for assisting the Ear in determining the various Sounds in the Human Body
Invented by Professors BAZZI and BIANCHI.

The above is a combination of the principle of the Phonograph and the Double Stethoscope, and by its use in auscultation the various sounds, whether natural or morbid, are intensified and rendered more distinct. Many of the sounds produced by the internal organs which can only be imperfectly heard, or are even not at all detectable, by the ordinary stethoscope can be heard with the greatest ease by means of this new instrument. Most of the normal and abnormal sounds of the heart and lungs can be easily detected through the clothes of a person in ordinary dress. Many of the sounds of deep-seated organs which cannot be heard with any instrument before in use can now be detected by the Phonendoscope, and it is expected by the inventors that this instrument will be of the greatest value to the physician and surgeon in helping to elucidate obscure points of diagnosis.

Price, with full instructions, in Case, 25/- post free.

Angier's Petroleum Emulsion.

WITH HYPOPHOSPHITES LIME AND SODA

WILL RELIEVE THE MOST

Stubborn Coughs.

It has been found especially efficacious in the treatment of chronic congested conditions of the tracheal and pulmonary mucous membrane attended by hypersecretion of mucus. In these cases the expectoration becomes more free, the pulmonic circulation is assisted, the respiration is easier, the troublesome cough is relieved, and the character of the sputa is altered.

It also appears to have some special soothing and quieting power to relieve the persistent, harsh, and irritating cough so common after Influenza, and often quickly affords relief after every other remedy has failed.

All Wholesale Chemists and Principal Retail Chemists keep it. Free Samples on application.

ANGIER CHEMICAL CO., 32, SNOW HILL, LONDON, E.C.

BRAIN-FAG.

BRAIN FAG is an expression used to convey the idea of that condition of the brain where it is tired, worn out or broken down from various causes, such as worry, anxiety, over-work and excesses of various kinds. In cases of this kind the first impulse is to resort to stimulants, which may give temporary relief, but wherever there is stimulation there is bound to be a reaction which leaves the sufferers in a far worse condition than they were before.

WORRY, ANXIETY, OVER-WORK.

CELERINA!

GENTLE, NATURAL STIMULANT.

What we want in these cases is a brain food combined with a stimulant that will not react. Stimulation without reaction is apparently an anomaly, but the experience of the medical profession all over the world proves that in **CELERINA** we have such a combination. Besides being a gentle and natural stimulant, it also serves as a food to the shattered nervous system, and soon restores and maintains it in its normal condition.

RIO CHEMICAL CO., ST. LOUIS, MO., U. S. A.

The above Preparation is Prepared Exclusively for the Prescriptions of Medical Men. A Sample will be Sent Free to any Medical Man who desires to test it, on application to

BURGOYNE, BURBIDGES & CO., 16 Coleman Street, LONDON,

MEDICINAL PREPARATIONS.

NAME.	PROPERTIES.	DOSE.
ANTINOSINE	Iodoform substitute, being the sodium salt of Nosophen, a blue powder soluble in water.	As gargle and for irrigation in 0·1 to 0·25 per cent. solution, or undiluted in powder form like iodoform.
CARNIFERRINE	Iron salt of phospho-carnic acid, containing 30 per cent. iron in an active and easily assimilable form.	8 grains daily for adults, 3 to 5 grains for children, as a powder or in tablets or pills.
CREOLIN	A refined preparation of JEYES' FLUID for medicinal purposes, forming an emulsion with water, used as a powerful non-irritating antiseptic.	In ½ to 2 per cent. solution.
EUDOXINE	A reddish-brown tasteless powder, insoluble in water, combining the properties of Nosophen and Bismuth. Used as an internal antiseptic.	5 to 8 grains thrice daily; children ¾ to 3 grains thrice daily according to age; infants ⅛th to ¾ grains thrice daily. Best given in powder or pills.
JEYES' FLUID	A coal-tar disinfectant of uniform, constant, and active composition, used as a general disinfectant.	In 2 to 5 per cent. solutions, and in soaps, disinfectant powders, &c.
JEYES' SOLUBLE FLUID	A refined preparation of JEYES' FLUID, forming a clear solution with water; for sterilisation of surgical instruments and as a general antiseptic.	For sterilisation purposes, in 2 to 3 per cent. solution; for irrigations, in ½ to 1 per cent. solution.
LYSIDINE	A colourless liquid and uric acid solvent in gouty disorders.	30 to 150 minims in a pint of aërated water, given daily.
MIGRAININE	A powder easily soluble in water, combining the action of antipyrine and caffeine. Used in neuralgia, migraine, and sick headaches.	16½ grains, best given in water and taken on an empty stomach, after which two hours' rest should be enjoyed. A second dose should only be given in exceptional cases, and not before the lapse of two hours after taking the first dose.
NOSOPHEN	Tetra - iodo - phenolphtalein, a greenish - yellow powder, insoluble in water, tasteless, and odourless, containing 61·7 per cent. iodine. A powerful substitute for iodoform, free from poisonous and irritant properties.	Used undiluted, and also diluted in the form of powder, ointments, paste, gauze, &c. Internally in doses of 5 to 8 grains.
SYMPHOROL N **" L** **" S**	The sodium, lithium, and strontium salts of caffeine-sulphonic acid. A white powder soluble in water, used as a powerful diuretic.	15 grains four times a day, given in water.

AWARDS.

GOLD MEDAL, International Health Exhibition, London, 1884.
FIRST ORDER OF MERIT AND MEDAL (Highest Award), Adelaide, 1887.
HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Liquor Pancreaticus (Benger).

For the preparation of peptonised or partially digested milk and other articles of food.

Simple directions for use enclosed. In 4 oz., 8 oz., and 16 oz. Bottles.

The *British Medical Journal* of April 1st, 1882, in an article on Benger's Preparations, says:—"Time and use have justified the claims put forward for these preparations."

The *London Medical Record* of March 15th, 1882, says:—"These are undoubtedly a great advance on any previous attempt in this direction. . . . The introduction of these preparations is a distinct advance in therapeutics."

The *Medical Times and Gazette* of September 8th, 1883, says:—"Benger's Preparations have deservedly a very high reputation, and are all largely used."

Liquor Pepticus (Benger).

An exceedingly active fluid pepsine, without disagreeable taste.

DOSE.—One or two teaspoonfuls with meals. In 4 oz., 8 oz., and 16 oz. Bottles.

Benger's Peptonised Beef Jelly.

A delicious quick restorative for Invalids and the Aged. In patent glass jars, no metallic contamination possible. · Retail, 2s. each.

The Lancet says:—"It is a most valuable form of concentrated food."

The *London Medical Record* says:—"Invaluable for old people; also in convalescence from acute diseases."

A Physician writes:—"I feel I cannot express my gratitude to you sufficiently, as your Beef Jelly is the only thing my niece can retain, and it has certainly kept her alive for the last week."

Benger's Peptonised Chicken Jelly.

In similar glass jars. Retail, 2s. each.

The Lancet says:—"Mr. Benger's Preparations are now so well known that all we need say of the sample before us is—that it is excellent. It has a delicate chicken flavour."

The *Medical Press* says:—"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in the treatment of the sick."

Benger's Preparations may be obtained through all Retail and Wholesale Houses and Shippers, or of the Manufacturers—

Tabellæ and Hypoderms.

Compressed Medicines.

Tabellæ.—Since 1876 ALLEN & HANBURYS have manufactured drugs in the compressed form, and have from time to time introduced various improvements. Those composed of sparingly soluble substances, such as *Sulphonal*, &c., are made to speedily disintegrate on coming in contact with moisture; those made of bitter drugs, such as Cascara Laxative, Quinine, &c., are *sugarcoated*, unless otherwise ordered.

Made in hundreds of Formulæ.

SUGAR-COATED CASCARA TABELLÆ.

SOME OF THE MORE IMPORTANT TABELLÆ ARE:—

*Arsenious Acid, 1-100, 1-50
Aconite Tinct., min. 1
*Aloin Comp.
{Aloin, 1-5
{Strych., 1-60
{Ext. Bellad., 1-8
{Ipecac., 1-6
Ammon. Brom., gr. 5 and 10
,, Chlor., gr. 3 and 5
Antacid
Antifebrin, gr. 3
Antim. Tart. and Ipecac., gr. 1-100 each
Antipyrin, gr. 5
Bismuth and Soda
,, Carb., gr. 5
,, Soda and Ginger.
,, Subnit., gr. 5
Caffeine Cit., gr. 1 and 2
,, Hydrobrom., gr. 2
Calcium Sulphide, gr. 1-10, 1-4, and 1-2
Calomel, gr. 1-10, 1-4, 1-2, and 1
Carbo Lig., gr. 5 and 10
Cascara Ext., gr. 2
Cascara Comp.
{Ext. Cascara, gr. 1
{Euonymin, gr. ½
{Ext. Hyoscyamus, 1-3
{Nux Vomica, 1-16
Chloral Hydrate, gr. 5
Cocain, 1-20, 1-10, 1-8, 1-5, 1-4½
Cupri Arsenitis, 1-50
Dover's Powder, gr. 5
*Easton's (1=1 dr. Syrup)
*Ergotin, gr. 3
Exalgine, gr. 1-8, 1-2, 1, and 3
Euonymin, gr. 1-4 and 1
Blaud Ferrugin, gr. 5
Gummi Rub. c. Cocain, 1-20
Hyd. c. Creta, 1-4, 1-3, 1-2, and 1 gr.
*Ichthyol, gr. 2½
Ipecac. Pulv., gr. 1-30, 1-20, 1-10, 1-4, and 5
Lithia Co. (Mr. Hugh Lane's revised formula)
Lithia Salicylas, gr. 2
Sulphur Precip., gr. 2
Quinine Salicyl., gr. 1-3
Morphia Sulphate, gr. 1-8, 1-4, 1-3, 1-2
Nitro-Glycerine, gr. 1-100th
Papain, gr. 1, 2, 3, 5
Papain, gr. 1, and Pepsin, gr. 2
Papain, gr. 2, and Pepsin, gr. 3
*Pepsin, gr. 2
*Peptonic
Phenacetin, gr. 5
Pot. Chlor.
,, ,, Borax
,, ,, ,, and Cocain, gr. 1-100th or 1-20th
Podophyllin, gr. 1-8, 1-4, & 1-2
*Quinine Bisulph., gr. 1-10, 1-2, 1, 2, 3, 5
Rhei Zingib. and Soda
Saccharin, gr. ½
Salicin, gr. 5
Salipyrin, gr. 5
Salol, gr. 5
*Santonin, gr. 1; Calomel, gr. 1
Soda Mint
Sodii Bromid., gr. 5

Thyroidin
Urethane, grs. 3 and 5

Those marked with an asterisk are Sugar-coated, unless otherwise ordered.

Compressed Medicines—(*Continued*).

All Tabellæ sold in *bulk* and conveniently put up in Vinaigrette Bottles for the pocket; with name and trade-mark (a plough) on label

at 1/-, 2/6, and 4/6 each,

except **Saccharin,** which are

9d., 2/-, and 4/-.

Sublimate Tabellæ, for quickly preparing Solutions for sprays and lotions of definite strength, are sold in bottles (retail) **at 9d. and 1/6.**

They will be found more readily soluble than any Sublimate Tabellæ previously offered to the profession. They produce a clear, faint-blue solution, thus distinguishing them from Tabellæ, which are swallowed, and avoiding the possibility of mistake.

"Hypoderms" is the name applied by ALLEN & HANBURYS to their Tabellæ for quickly preparing **Hypodermic Solutions** (without the aid of heat or trituration). Careful observation proves that the materials used in their manufacture do not produce the slightest irritation, and more important still, do not in the least affect the properties of the alkaloid or other drug used. Improved methods of manufacture have now enabled us to produce "HYPODERMS" which do not deliquesce in a moist atmosphere, and which preserve the active properties of the drug unaltered and unimpaired for any length of time.

Further advantages are:—

The dose is exactly known, and they can be dissolved in the syringe itself.

All the more important drugs and alkaloids may be obtained in the form of "Hypoderms." For complete list see pp. 83-84 in **"Notes on some New and Recent Remedies,"** post free to the Medical Profession on request.

In tubes at 7/- per doz.

Also **Hypodermic Pocket Cases,** containing best English made Syringe, Needle, &c., and space for "Hypoderms."

Full particulars on application.

Saccharin.

A Sugarless sweetener for the food and beverage of those suffering from Gout, Diabetes, Dyspepsia, &c. Supplied in bottles for the pocket as

Compressed Tabellæ,

at -/9, 2/- and 4/- each,

and **Soluble Salt,**

at 1/-, 2/4, and 4/6 each.

Also in the liquid form **Elixir,**

at 1/-, 2/6, and 5/-.

☞ Physicians when prescribing ALLEN & HANBURYS' Tabellæ or other preparations, such as Malt Extract, Saccharin, and its preparations, Soluble Gelatine-coated Pills, Improved Capsules, &c., which are not known by any distinctive or registered name, can indicate their intentions by the addition of the initials "A. & H.," which, for convenience in prescribing, ALLEN & HANBURYS have registered as a Trade-mark, thus:—

℞. Tab. antipyrin gr. v. A & H.

"The maintenance of Nutrition is the KEYNOTE of the successful treatment of Phthisis."—THE LANCET.

Bynol. "The Perfected" Malt & Oil.

Physiology.

This can be best considered by taking separately its two constituents:—

1. The **Malt Extract** used contains an amylolytic ferment called diastase, of the fullest activity. Its special function of converting starchy foods into a soluble sugar which can be easily absorbed renders this preparation at once invaluable for aiding assimilation.

In weakly and cachectic conditions the activity of the natural allied ferment ptyaline becomes greatly deficient, with the consequence that much ingested material is never digested.

The Malt Extract being semi-fluid, and possessing a characteristic sweet taste, is therefore physically a very convenient vehicle for emulsifying and disguising the slight taste of the other constituent—**Cod Liver Oil.**

2. The physiological properties and fate of the latter body are complex; its equivalent in heat-units as regards the animal body is at least two-and-a-half times that of Meat Extract (Liebig); that is to say, it is at least two-and-a-half times as valuable as Meat Extract in maintaining the body weight.

Long use has shown that, in atrophic conditions of the absorbing mechanism of the bowel, Cod Liver Oil is not only more easily emulsified, but more easily taken up by the villi of the small intestines and passed on to the lacteals.

In the **"Perfected" Cod Liver Oil,** where the formation of certain oxidation products irritating to the stomach is avoided, we have perhaps the ideal form of fat-food.

Milk, cream, etc., are liable to produce butyric and other allied fatty acids, of little use except to irritate the gastric and intestinal mucous membrane.

To more perfectly understand the part played by Cod Liver Oil, the digestion of fat-foods is roughly as follows:

In the stomach slightly, but chiefly in the duodenum, by the action of the pancreatic ferment, fats are—

1. *Emulsified*, that is, broken up into minute oil globules, each surrounded by what is known as a haptogen membrane. In this physical state absorption is possible by the villi, the oils being unaltered.

2. *Saponified*, that is, split into fatty acids and glycerine, both capable of absorption by the intestine.

Therapeutics.

The above considerations enable us to understand more clearly the immense use Malt Extract and Cod Liver Oil, especially in combination, have in wasting diseases.

In *Phthisis*, for example, the digestive ferments are of lowered activity, and the introduction of a modicum of artificial ferment not only increases the actual amount of food assimilated, but the power of the enfeebled ferments to assimilate.

The almost constant rise of temperature above the normal is maintained chiefly at the expense of the fatty constituents of the body; hence the wasting. This, experience has shown, can best (putting aside questions of hygiene) be combatted by increasing considerably the amount of fat-food and carbohydrate food.

When absorbed, the part played by fat-food is practically two-fold:—

1. It becomes the source from which the surplus fat stored up in various parts of the body may be replenished.

2. Fat-food is one of the chief sources of animal heat, as shown above.

As we have seen, the Cod Liver Oil is the best of the class of fat-foods, especially in an enfeebled condition, and, combined with Malt Extract, as in Bynol, further assists the assimilation of the extra carbohydrate ingested.

That what is physiologically is also clinically true cannot be better illustrated than in the remarks made by the late Sir ANDREW CLARK in a lecture at the London Hospital:—

"I have said that these fibroid cases are poor creatures, thin and white, and have what may be called nutritive debility, and the question is, What am I to do with them? You cannot do better than endeavour to make the patient walk in the way of physiological righteousness. But that sometimes will not do. Some people may be physiologically well behaved, and somehow they do not thrive on it. Can you do anything in those cases? There are two remedies which sometimes do succeed where the ordinary diet will not succeed in nourishing the patient—the one is Cod Liver Oil and Malt given with food—a preparation called Bynol—and the other is the remedy called Bynin Emulsion, consisting of Hypophosphites, Oil, and Malt; both are prepared by Messrs. ALLEN & HANBURYS. These are two good nutritive agents in promoting nutrition."

☞ *"A perfect combination of Malt Extract and Cod Liver Oil."*—BRITISH MEDICAL JOURNAL.

GOLD MEDAL, World's Exhibition, AMSTERDAM, 1895.

Up-to-Date Physicians! Please prescribe that splendid Non-Secret Remedy

= TERRŌL =

THE TASTELESS COD LIVER OIL SUBSTITUTE.

THIS remarkable Drug is nothing but a very refined, odourless product of Petroleum. Its superiority over Cod Liver Oil and any Compounds, Mixtures, and Emulsions of that Oil is as follows:—

TERRŌL never becomes rancid, nor will it ferment like malt and oil!
It has absolutely no taste or odour. It does not repeat or nauseate!
It never becomes repugnant! It is not aperient!
It does not upset the stomach or bowels! It is soothing and antiseptic!
It can be administered to the youngest child or to the weakest patient!
Its dose is so small; and it is much cheaper than the finest Cod Liver Oil and all the highly advertised mixtures, emulsions, or malt preparations.

These are not only the opinions of the Company, but of the entire Profession in the United States and large numbers of the Profession in the United Kingdom who have yet prescribed the drug.

INDICATIONS.—Asthma, Bronchitis, Phthisis in every stage, Pneumonia, Cough, Sore-throat, Whooping-cough, Laryngitis, Marasmus, Influenza, and the General Debility following any illness.

IT IS NOT A PATENT MEDICINE, NOSTRUM, COMPOUND, OR EMULSION, BUT A PURE, SIMPLE BODY.

THE HISTORY OF A NEGLECTED SAMPLE.

"TOOTING, November 4th, 1895.

"*The Manager, the Terrōl Co.*

"DEAR SIR,—

"I have had by me a sample bottle of 'Terrōl' for some months. The other day a phthisical man came and asked me if I could give him anything that would allay his distressing cough at night. He had been an out-patient at Brompton Hospital for some time past; he could get no relief, and even the Cod Liver Oil he had turned against, as it produced scarcely any effect on his nutrition—certainly none on his cough. I gave him the bottle of your preparation, just thinking to give it a trial, and not expecting any extraordinary result from its use. He came two days afterwards and told me it was the first real relief he had had. Nothing he had ever taken did him so much good. In the face of this fact I am anxious to give it a further trial in three cases under my care. I should be obliged if you would send me a further supply of 'Terrōl. I thought it right that you should know the above facts, and I think that I can safely say that I shall always recommend it.

"Yours very truly,

"——, M.D.

"The way in which the Terrōl acted was as an expectorant of the highest order, and giving a feeling of great relief, subsequently, of the coughing fit."

TERRŌL obtainable through all Chemists. In bottles, 4/6 (1 lb., 128 doses) and 1/6 (5 oz., 40 doses); thus costing less than ½d. per dose to the patient.

A TRIAL SAMPLE & LITERATURE SENT CARRIAGE PAID TO ANY QUALIFIED PHYSICIAN IN THE BRITISH ISLES.

Wholesale to the Profession, of all Drug and Proprietary Medicine Houses, and of

The TERRŌL CO., 30, 32, 34, Devonshire Road, Forest Hill, LONDON, S.E.

CARNRICK'S PEPTONOIDS.

CARNRICK'S BEEF PEPTONOIDS
(POWDER).

THIS preparation contains the albuminous and nutritive constituents of the choicest beef, wheat, and milk, in a concentrated and palatable form. By reason of its composition and of the method of preparation, it possesses a nutritive value that has long been recognised as incontestably greater than that of any other preparation of beef. As a fine, dry powder, free from moisture and inert material, "Beef Peptonoids" has obviously a higher proportion of nutritive constituents than any of the liquid preparations of beef. It is not only as a *Concentrated Food*, however, that it has claims upon the support of the Profession. It furnishes a very assimilable form of nourishment, being *partially* peptonised, and thus, while free from the objections sometimes raised to peptones, it is yet adapted for use in cases where easily digested food is alone admissible. This fact, together with its concentrated character, opens up a wide field of usefulness for "Beef Peptonoids." Another characteristic that deserves mention is that the constituents of "Beef Peptonoids" are carefully sterilised during manufacture. "Beef Peptonoids" as an *aseptic* food, one, moreover, that is absorbed from the stomach, leaving no residue to occasion trouble in the bowel, is admirably adapted for use in Typhoid Fever. In fact, both the "Beef Peptonoids" and "Liquid Peptonoids" have achieved notable successes in that connexion. The uses of such a nutritious and restorative food as "Beef Peptonoids" will naturally suggest themselves to the Physician. We may say that clinical experience on an unusually large scale has demonstrated its great services in the treatment of Fevers generally, in convalescence, and in the dieting of phthisical patients. Whenever there is wasting or mal-nutrition, "Beef Peptonoids" seems worthy of trial, since it

"Contains in a highly concentrated form the elements of a complete food—nitrogen, fat, saccharine matter, mineral salts, phosphoric acid, and iron."—Prof. C. MÉHU, Paris.

"It is by far the most nutritious and concentrated food I have ever met with."—Prof. ATTFIELD, London.

LIQUID PEPTONOIDS

Is a solution of the Beef Peptonoids powder in the form of an exceptionally palatable cordial. Liquid Peptonoids contains both the stimulating and nutritious properties of Beef, is readily assimilated, affords a large amount of nutriment in small bulk, and exercises a marked influence on the appetite and strength of the patient. It is rendered *aseptic* by sterilisation, and its stimulating effect on the digestive organs, whereby it contributes to improved nutrition, is not its least valuable feature.

"A very powerful and agreeable tonic and stimulant. A very valuable CONDENSED FOOD."—THE LANCET.

We also put up Liquid Peptonoids with Coca, and Peptonoids Iron and Wine.

SAMPLES FREE OF CHARGE AND CARRIAGE PAID TO MEDICAL MEN.

CARNRICK & CO., Ltd., 24 and 25, Hart St., Bloomsbury, London.

"LANOLINE,"

The Discovery of Professor LIEBREICH,

WILL REPLACE THE

NATURAL FAT OF THE SKIN,

AND IS WIDELY

Prescribed by Physicians and Surgeons for all Ointments,

AS IT

is aseptic;

does not turn rancid;

is rapidly absorbed by the skin;

AND

can be mixed with any proportion of water.

A striking illustration of the power of "LANOLINE" of resisting influences which tend to decompose ordinary fats is afforded by some experiments carried out in 1890 by Surgeon-Major M. G. KING, with the design of obtaining a preparation of vaccine lymph which should withstand the destructive action of the heat in India. KING tried preparations with glycerine, boroglycerine, soft paraffin and "LANOLINE."

The mixtures containing glycerine decomposed in a week, those of boroglycerine in a fortnight and sometimes sooner, while 1 part of lymph with 4 parts of "LANOLINE" kept completely for at least 40 days.

Dr. A. GOTTSTEIN showed that "LANOLINE" not only was free from germs, but also **PREVENTED** their growth.

Dr. S. ECCLES said that he preferred "LANOLINE" to soft paraffin and other preparations.—BRIT. MED. ASSOC., 1887.

Dr. W. G. SMITH proves the virtue of "LANOLINE" in acne and chapped hands.—BRIT. MED. JOUR., June 12th, 1886.

Dr. SHOEMAKER describes "LANOLINE" as a mild and soft ointment, valuable for a great number of obstinate skin diseases.—BRIT. MED. ASSOC., 1886.

Professor ROSENBACH speaks highly of "LANOLINE" for the prevention and relief of decubitus.

Prof. NILS O. GADDE prescribes "LANOLINE" in Frostbites with great success.

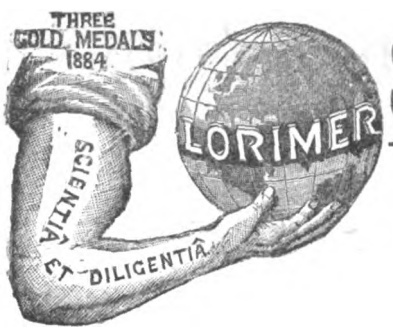
Dr. R. KLEIN calls attention to the value of a "LANOLINE" cooling ointment containing 50 per cent. water for the successful relief of the itching of measles, scarlatina, chicken-pock, or of any origin.

Dr. STELLWAGON considers "LANOLINE" indispensable in psoriasis.

Dr. NEWTH treated obstinate ulcers of the irritated kind with "LANOLINE" ointments.

Dr. MACKEY used it in all skin diseases, and particularly in chronic joint affections of rheumatic origin.—BRIT. MED. ASSOC., 1886.

Physicians should always prescribe "LANOLINE" diluted with about one-third of its weight of soft paraffin; or they can prescribe this mixture of "LANOLINE" and soft paraffin under the name of



"UNGUENTUM LANOLINI."

Winch. Quarts - - - - - - - 2/6 lb.

Is not a quack preparation or secret nostrum; the formula is printed on every label.

The formula is original, founded upon scientific principles, and has stood the test of practical experience. There is no other preparation of the hypophosphites which contains so large a proportion (about six grains to the fluid drachm) of the salts employed.

All its constituents are in perfect and permanent solution, the last dose being identical, under all circumstances, with the first. There is consequently no possibility of danger from the precipitation of strychnine, as is the case with preparations that require shaking to distribute the dose.

It is neutral, or very slightly alkaline, and can therefore be taken without ill effect by persons afflicted with sensitive stomachs, which would probably reject acid or strongly alkaline preparations.

Other preparations of similar name are either strongly acid, of unknown composition (varying from half to three grains Hypophosphites to the drachm), or **deposit their active ingredients on standing;** *many* have all these faults.

CAUTION.

As we have had several cases brought under our notice where inefficient imitations have been dispensed instead of our Syrup, causing much disappointment and annoyance, Physicians will oblige by writing "Syr. Hypophosph. Co. (Lorimer)."

REPORT OF THE ACADÉMIE DE MÉDECINE OF FRANCE.

Apollinaris

"THE QUEEN OF TABLE WATERS."

"The results of the recent investigations "in Paris and the Report of the Académie "de Médecine of France have placed "Apollinaris Water at the head of all the "waters examined for purity and freedom "from disease germs."

BULLOCK'S PEPSINA PORCI.

DOSE—2 to 4 grains.

BULLOCK'S ACID GLYCERINE OF PEPSINE.

DOSE—1 to 2 drms.

In this preparation advantage has been taken of the solubility of Pepsine in Glycerine to produce a convenient and desirable *liquid form* of this valuable medicine; whilst the preservative qualities of the menstruum confer upon the Acid Glycerine of Pepsine the property of keeping for any length of time.

May be prescribed with most substances compatible with Acids. In 4-oz., 8-oz., and 16-oz. Bottles, and in Bulk.

The published experiments of G. F. DOWDESWELL, Esq., M.A.Cantab., F.C.S., F.L.S., &c., Dr. PAVY, Professor TUSON, the late Professor GARROD, Dr. ARNOLD LEES, and others, conclusively demonstrate the excellence, high digestive power, and medicinal value of the above preparations.

In prescribing either of the above preparations it is suggested to insert in parenthesis as follows (BULLOCK).

J. L. BULLOCK & CO., 3, Hanover St., Hanover Sq., London, W.

FAT FOR CHILDREN.

"VIROL."

A PREPARATION OF

BONE-MARROW.

"Ideal form of FAT for Children and Invalids."—THE LANCET.

9d., 2s. 6d., 3s. 6d., and 21s.

THE LIQUOR CARNIS CO.,
Aston Clinton, Bucks.
Depôt: 192, Aldersgate St., London.

AN IDEAL
Food for Infants.

"Fat is wanted for every tissue formed and forming, especially for brain and nerve cell, and for the marrow cells. In children who are fed upon a deficient amount of fat, the bony structures are imperfect and slow of growth; in a word, deficiency of fat in the food (of infants) is one of the chief factors in the production of rickets."—CHEADLE.

FAT.—"The importance of a sufficiency of fat in the dietary of children cannot be over-estimated."—MILNER FOTHERGILL.

"OUR TREASURES, AND HOW TO KEEP THEM."

This little book deals essentially with the value of **Fat** and **Iron** in Infant Feeding, and, having a few copies left, will send to first applicants.

VIROL {INFANT'S FOOD, Rich in FAT and IRON.}

"A preparation containing the Red and Yellow Bone-Marrow, with the fats and proteids of Raw Eggs, combined with Extract of Malt in physiological proportions."—THE LANCET.

"For children and invalids requiring a supply of fat material in addition to their ordinary food, 'Virol' appears to be well devised to serve a useful purpose."—BRITISH MEDICAL JOURNAL.

HUMANISED MILK.

"Virol occupies the unique position amongst food-stuffs in being a link between the diet of infancy and adolescence, so that a sudden transition is easily avoided. If added to Cow's Milk, Virol renders it far more like human milk than the cumbersome and complicated method of Liebig or the more homely and delusive one of adding water and sugar."

The above are Extracts from "Our Treasures," a Free Copy of which will be posted by desire.

Recent analysis and report published by the BRITISH MEDICAL JOURNAL *on page 71 of the 7th inst.*

Samples of any article sent for trial from the L. C. C.'s country offices, Aston Clinton.

TAMAR INDIEN GRILLON.

A laxative, refreshing, and medicated Fruit Lozenge, very agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION,

HÆMORRHOIDS, BILE, CEREBRAL CONGESTION, HEADACHE, LOSS OF APPETITE, INTESTINAL OBSTRUCTIONS, &c.,

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect—that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Wholesale—London: E. GRILLON, 47, Southwark Street, London, S.E.

Sold by all Chemists and Druggists, 2s. 6d. a box, stamp included.

DR. ZED'S SYRUP.

Gold Medal, Exhibition, Vienna, 1883.

Composed of CODEINE, TOLU, &c.

Pure Codeine produces a calm sleep without any heaviness of the head (Dr. Gubler). If to this be added the sedative effects of the Balsam of Tolu and of Cherry Laurel Water, we obtain the principles of Dr. Zed's Syrup against whooping-cough, bronchitis, phthisis, insomnia, &c.

Paris: 22, RUE DROUOT.

Dr. Zed

London: G. JOZEAU, Chemist, 49, Haymarket.

GOLD MEDAL, INTERNATIONAL EXHIBITION, 1884. SILVER MEDAL, CALCUTTA EXHIBITION, 1883.

MIST. PEPSINÆ CO. c. BISMUTHO (HEWLETT'S).

COMPOSITION—Pepsine, Liq. Bismuthi, Sol. Opii Purif., Hydrocyanic Acid, P.B., Tinct. Nux Vomica, &c.

Highly recommended in various forms of dyspepsia, having a direct action upon the mucous membrane of the stomach and intestines as a sedative. It can be administered with marked and almost instantaneous effect in the irritative form of dyspepsia, more especially when *pyrosis* is a conspicuous symptom and pain occurs an hour or more after food. In simple neuralgic gastric pain following eating, occurring in feeble subjects, it is especially indicated, and even in *carcinoma* it has been used with great success in alleviating pain and vomiting.

In the dyspepsia of patients, dependent upon some organic disease, and where there is a decided loss of nerve power, it is of singular service. Thus, for instance, a person after a meal complains of a peculiar gnawing and emptiness with slight pain at the epigastrium—evident signs of general relaxation and loss of nerve power. Clinical experience has shown that it is of great service as a tonic and stomachic. A portion of its value arises, it may be, from its action upon the spinal motor nerve-centres. Be these things as they may, experience has abundantly demonstrated the value of the compound as a stomachic, antidyspeptic, and tonic. In general functional atony and relaxation, and in the various forms of dyspepsia, constipation, or diarrhœa, connected with atony of the visceral muscular coat, the MIST. PEPSINÆ CO. C. BISMUTHO is a very valuable remedy. In the *exhausting purging of Phthisis* accompanied with night sweats and restlessness Dr. Mathews, of Nantwich, has used it with marked and appreciable effect. **Price 10s. 6d. per lb.** **Dose—Half to one drachm, diluted.**

Physicians will please write "Mist. Pepsinæ Comp. (Hewlett's)."

VIN MARIANI

(ERYTHROXYLON COCA.)

More than 2000 physicians have certified to the immense sustaining, recuperative, and nourishing properties of this wine, which is indicated in cases of

OVER-EXERTION,
NEURASTHENIA,
NERVOUS DEPRESSION
SLEEPLESSNESS,
NERVOUS DEBILITY
CONVALESCENCE,
VOCAL FATIGUE.

When prescribing it the Medical Profession are strongly advised to specify "VIN MARIANI" in order to avoid the substitution of imitations often worthless, and consequently disappointing in effect.

Price 4s. per Bottle; or 45s. per Dozen. To the Medical Profession any quantity post free, at rate of 42s. dozen, from WILCOX & CO., 239, Oxford-street, London. Illustrated Treatise on Coca Free.

CIGARES DE JOY

ASTHMA
CHRONIC BRONCHITIS

One of these Cigarettes gives IMMEDIATE RELIEF in cases of ASTHMA, CHRONIC BRONCHITIS, HAY FEVER, COUGH, and SHORTNESS OF BREATH, and their daily use effects a COMPLETE CURE. The contraction of the air tubes, which causes tightness of chest and difficulty of breathing, is at once lessened by inhaling the medicated smoke of the Cigarette; a free expectoration ensues, and the breathing organs resume their natural action. Persons who suffer at night with COUGHING, PHLEGM, and SHORT BREATH find them invaluable, as they instantly check the spasm, promote sleep, and allow the patient to pass a good night.

These Cigarettes are perfectly harmless, and can be smoked by ladies, children, and the most delicate patients, as they are pleasant to use and contain no substance capable of deranging the system.

Price 2s. 6d. from WILCOX & CO., 239, Oxford-street, London, and all Chemists. To the Medical Profession, 1s. 10d. post free.

CRYSTALLIZED DIGITALINE Nativelle.

The Paris Academy of Medicine awarded a prize of 5000 francs to M. Nativelle for the discovery of CRYSTALLISED Digitaline.

CRYSTALLISED DIGITALINE (NATIVELLE) is a definite substance that can always be relied on and administered with exactitude. After a few doses the pulsations of the heart become slower, more regular, and more energetic.

Prepared in Bottles of 60 granules, each granule containing a 240th grain (½ milligramme). A Sample, with Opinions of the Press and Medical Profession, free by post from WILCOX & CO., 239, Oxford-street, London. Sold by all Chemists.

WILCOX & Co.'s DESICCATED EXTRACT OF MALT

A Concentrated, Nutritive, and Digestive Food for INVALIDS and CHILDREN.

This preparation embodies all the beneficial properties of the most carefully prepared semi-fluid extracts, and possesses the additional advantages of greater richness in DIASTASE and the impossibility of fermentation. This Powder may be eaten between bread-and-butter or dissolved in liquid, and, being a natural solvent of farinaceous material, it is strongly recommended as an adjunct to Children's Food and for ladies whilst nursing.

Prepared only by WILCOX & CO., 239, Oxford-street, London, and put up in large bottles at 2s. 6d. each. Messrs. W. & Co. will be pleased to forward a sample of the above to any of the Medical Profession.

Flitwick

A REMARKABLE ENGLISH NATURAL CHALYBEATE.

An unrivalled Specific for ANÆMIA, CHLOROSIS, & GENERAL DEBILITY.

THE LANCET, Oct. 24th, 1891:—Containing in each gallon more than 170 grains of iron as per-salt, in a nearly neutral solution, along with certain peaty constituents.

BRITISH MEDICAL JOURNAL, Feb. 11th, 1893:—"The results of our analyses show that the water contains a large amount of iron, entirely in the 'ferric' state, with a moderate amount of alumina and small amounts of lime and magnesia, combined mainly with sulphuric acid as sulphates; and very marked amounts of the organic compounds derived from peat, the total iron amounting to 96·5 parts by weight per 100,000 parts by weight of the water. It has a pleasant acid taste entirely devoid of 'inkiness,' and it is probable that the peculiar manner in which the iron is held in solution and combination renders it capable of being readily absorbed and assimilated, and so far as our observations go the water does not affect the teeth nor produce constipating effects."

THE KOLA NUT.

"The State Department has been calling upon the United States consuls in Africa for specific information in regard to the kola nut, which, by its peculiar action upon the muscular system, enables the African negroes to make long journeys bearing enormous loads under tropical suns and across difficult country without food. Authentically reported cases prove that even an old negro may carry a 176lb. bag of coffee for leagues by chewing a single nut slowly. Mr. R. P. Porley, U.S. consul at Sierra Leone, has sent in the first report upon the subject, treating of the methods of growing and preparing the nuts. According to him, the natives eat them early in the morning as a stay against ordinary food while travelling, and in the evening to induce sleep."—EVENING NEWS, May 2nd, 1896.

VI-COCOA contains a large percentage of Kola Nuts in its purest and best form.

Sold in 6d. packets, and 9d. and 1s. 6d. tins.

UNIVERSAL TUBULAR WATER AND AIR BED

Prize Medals Sanitary Congress, 1878. Industrial Exhibition, York, 1879. Certificate of Honour, Sanitary Congress, 1879.

Brighton, 1881. International, 1881. Kensington, 1882.

POCOCK BROTHERS,

Patentees and Sole Manufacturers,

235, SOUTHWARK BRIDGE ROAD, LONDON.

Consists of a series of separate and distinct cylinders, any diameter and suitable length, made of Waterproof material either for Water or Air, fitting into a case which keeps them side by side, but slightly apart.

1. In cost it is less expensive.
2. It is warm and light, and well adapted for a camp or field-bed, being waterproof.
3. It is quickly filled and easily adjusted.
4. It admits of ventilation in the space between the tubes.
5. It can be regulated so as to relieve pressure from any part required.
6. By the addition of tubes it will raise one part of the body higher than the rest.
7. By the temporary removal of one or two tubes it affords room for the introduction of a bedpan.
8. It can be inclined to any angle (even when filled with water) to suit the condition of the patient.
9. It is free from noise and surging, so disagreeable to the invalid on changing his position on a water bed.
10. In case of injury to a tube it can be withdrawn, and a fresh one substituted at a trifling cost, and without loss of time; whereas the ordinary water-bed, if injured in any part (from being in one compartment), is rendered useless.
11. In the treatment of invalids, especially the insane, who are paralysed and have no control over their evacuations, they cannot lie in a pool of wet, the fluid passing away between the tubes.

ITS ADVANTAGES OVER ORDINARY WATER OR AIR BEDS ARE AS ABOVE.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

HUXLEY'S HYPOGASTRIC CEINTURE, OR UTERINE SUPPORT FOR HORSEWOMEN.

Dr. E. J. M. C. contributed the following letter to THE LANCET and BRITISH MEDICAL JOURNAL on October 15th, 1887:—

NEW UTERINE SUPPORT FOR HORSEWOMEN.

"Shortly after my association with the 'Wild West,' I asked the frontier girls whether the violent riding did not shake them considerably, and was told that at times they suffered a great deal of pain. I advised them to get abdominal belts to keep themselves together whilst riding; they did so, and felt great benefits therefrom. On talking the matter over with Mr. E. HUXLEY, of Old Cavendish-street, he suggested a uterine support, which consists of a peculiar-shaped pad, with two straps which cross over the sacrum, and are brought to the front and fastened with any amount of tightness the wearer may find desirable. I got him to make one for each of the girls, and they say they are such a comfort and support that they will never ride without them. I think the belt will prove a great blessing to ladies in the hunting-field, as well as to professional riders.

"98, Earls-court-road." "R. J. M——— C———, F.R.C.P.Ed.

Measures required—Circumference of Pelvis, or lower part of body, as for a truss. Price 25s.

HUXLEY'S SUPPORT FOR INJURY TO THE LARGE MUSCLE OF THE THIGH (RIDER'S SPRAIN).

Until this contrivance was devised the straining of the adductor muscles had met with no effectual relief. This apparatus is immovable when in use and simply perfect in action. *Measures required—Size of top of thigh and round pelvis, stating for which leg.*

E. HUXLEY, *13, OLD CAVENDISH STREET, W.*

DR. CALDECOTT writes to THE LANCET:—"To the Editor of THE LANCET.—Sir,—Observing letters on the above in THE LANCET of July 29th and August 5th, I venture, through your columns, to recommend sufferers from the injury to give a trial to 'Huxley's Support for Injury to the Large Muscle of the Thigh,' advertised in THE LANCET of August 5th. I first injured the muscle at polo about four years ago, and suffered off and on from the injury for three years, at times having to give up riding altogether for three weeks or so. The bandage roller ordinarily used in the hunting-field gave a certain amount of support, but even with it anything like a hard game of polo made riding the following day almost an impossibility. Last year my attention was drawn to the advertisement of Mr. Huxley, 13, Old Cavendish-street, W., and I sent for one of his supports. Within a week or two after commencing to wear it, my leg was, to all intents and purposes, well, and I have had no return of the injury though I have played polo regularly during the last twelve months. I still wear the support at polo as a precautionary measure, but after using it for a month I was able to discard it for ordinary riding. I cannot too strongly recommend a trial of the support to any sufferers from the injury.

"East Indies, August 28th, 1882." "I remain, Sir, yours faithfully, R. CALDECOTT, Surg.-Maj., Central India Horse."
